# Appendix D. SQL Conformance

This section attempts to outline to what extent Postgres Pro conforms to the current SQL standard. The following information is not a full statement of conformance, but it presents the main topics in as much detail as is both reasonable and useful for users.

The formal name of the SQL standard is ISO/IEC 9075 “Database Language SQL”. A revised version of the standard is released from time to time; the most recent update appearing in 2011. The 2011 version is referred to as ISO/IEC 9075:2011, or simply as SQL:2011. The versions prior to that were SQL:2008, SQL:2006, SQL:2003, SQL:1999, and SQL-92. Each version replaces the previous one, so claims of conformance to earlier versions have no official merit. Postgres Pro development aims for conformance with the latest official version of the standard where such conformance does not contradict traditional features or common sense. Many of the features required by the SQL standard are supported, though sometimes with slightly differing syntax or function. Further moves towards conformance can be expected over time.

SQL-92 defined three feature sets for conformance: Entry, Intermediate, and Full. Most database management systems claiming SQL standard conformance were conforming at only the Entry level, since the entire set of features in the Intermediate and Full levels was either too voluminous or in conflict with legacy behaviors.

Starting with SQL:1999, the SQL standard defines a large set of individual features rather than the ineffectively broad three levels found in SQL-92. A large subset of these features represents the “Core” features, which every conforming SQL implementation must supply. The rest of the features are purely optional. Some optional features are grouped together to form “packages”, which SQL implementations can claim conformance to, thus claiming conformance to particular groups of features.

The standard versions beginning with SQL:2003 are also split into a number of parts. Each is known by a shorthand name. Note that these parts are not consecutively numbered.

- ISO/IEC 9075-1 Framework (SQL/Framework)
- ISO/IEC 9075-2 Foundation (SQL/Foundation)
- ISO/IEC 9075-3 Call Level Interface (SQL/CLI)
- ISO/IEC 9075-4 Persistent Stored Modules (SQL/PSM)
- ISO/IEC 9075-9 Management of External Data (SQL/MED)
- ISO/IEC 9075-10 Object Language Bindings (SQL/OLB)
- ISO/IEC 9075-11 Information and Definition Schemas (SQL/Schemata)
- ISO/IEC 9075-13 Routines and Types using the Java Language (SQL/JRT)
- ISO/IEC 9075-14 XML-related specifications (SQL/XML)

The Postgres Pro core covers parts 1, 2, 9, 11, and 14. Part 3 is covered by the ODBC driver, and part 13 is covered by the PL/Java plug-in, but exact conformance is currently not being verified for these components. There are currently no implementations of parts 4 and 10 for Postgres Pro.

Postgres Pro supports most of the major features of SQL:2011. Out of 179 mandatory features required for full Core conformance, Postgres Pro conforms to at least 160. In addition, there is a long list of supported optional features. It might be worth noting that at the time of writing, no current version of any database management system claims full conformance to Core SQL:2011.

In the following two sections, we provide a list of those features that Postgres Pro supports, followed by a list of the features defined in SQL:2011 which are not yet supported in Postgres Pro. Both of these lists are approximate: There might be minor details that are nonconforming for a feature that is listed as supported, and large parts of an unsupported feature might in fact be implemented. The main body of the documentation always contains the most accurate information about what does and does not work.

### Note

Feature codes containing a hyphen are subfeatures. Therefore, if a particular subfeature is not supported, the main feature is listed as unsupported even if some other subfeatures are supported.

## D.1. Supported Features

| Identifier | Package | Description                                       | Comment                                                     |
|------------|---------|---------------------------------------------------|-------------------------------------------------------------|
| B012       |         | Embedded C                                        |                                                             |
| B021       |         | Direct SQL                                        |                                                             |
| E011       | Core    | Numeric data types                                |                                                             |
| E011-01    | Core    | INTEGER and SMALLINT data types                   |                                                             |
| E011-02    | Core    | REAL, DOUBLE PRECISION, and FLOAT data types      |                                                             |
| E011-03    | Core    | DECIMAL and NUMERIC data types                    |                                                             |
| E011-04    | Core    | Arithmetic operators                              |                                                             |
| E011-05    | Core    | Numeric comparison                                |                                                             |
| E011-06    | Core    | Implicit casting among the numeric data types     |                                                             |
| E021       | Core    | Character data types                              |                                                             |
| E021-01    | Core    | CHARACTER data type                               |                                                             |
| E021-02    | Core    | CHARACTER VARYING data type                       |                                                             |
| E021-03    | Core    | Character literals                                |                                                             |
| E021-04    | Core    | CHARACTER_LENGTH function                         | trims trailing spaces from CHARACTER values before counting |
| E021-05    | Core    | OCTET_LENGTH function                             |                                                             |
| E021-06    | Core    | SUBSTRING function                                |                                                             |
| E021-07    | Core    | Character concatenation                           |                                                             |
| E021-08    | Core    | UPPER and LOWER functions                         |                                                             |
| E021-09    | Core    | TRIM function                                     |                                                             |
| E021-10    | Core    | Implicit casting among the character string types |                                                             |
| E021-11    | Core    | POSITION function                                 |                                                             |
| E021-12    | Core    | Character comparison                              |                                                             |

| Identifier | Package | Description                                       | Comment |
|------------|---------|---------------------------------------------------|---------|

## D.2. Unsupported Features

The following features defined in SQL:2011 are not implemented in this release of Postgres Pro. In a few cases, equivalent functionality is available.

| Identifier | Package | Description                                       | Comment |
|------------|---------|---------------------------------------------------|---------|

## D.3. XML Limits and Conformance to SQL/XML

Significant revisions to the XML-related specifications in ISO/IEC 9075-14 (SQL/XML) were introduced with SQL:2006. Postgres Pro's implementation of the XML data type and related functions largely follows the earlier 2003 edition, with some borrowing from later editions. In particular:

- Where the current standard provides a family of XML data types to hold “document” or “content” in untyped or XML Schema-typed variants, and a type `XML (SEQUENCE)` to hold arbitrary pieces of XML content, Postgres Pro provides the single `xml` type, which can hold “document” or “content”. There is no equivalent of the standard's “sequence” type.
- Postgres Pro provides two functions introduced in SQL:2006, but in variants that use the XPath 1.0 language, rather than XML Query as specified for them in the standard.

This section presents some of the resulting differences you may encounter.

### D.3.1. Queries are restricted to XPath 1.0

The Postgres Pro-specific functions `xpath()` and `xpath_exists()` query XML documents using the XPath language. Postgres Pro also provides XPath-only variants of the standard functions `XMLEXISTS` and `XMLTABLE`, which officially use the XQuery language. For all of these functions, Postgres Pro relies on the libxml2 library, which provides only XPath 1.0.

There is a strong connection between the XQuery language and XPath versions 2.0 and later: any expression that is syntactically valid and executes successfully in both produces the same result (with a minor exception for expressions containing numeric character references or predefined entity references, which XQuery replaces with the corresponding character while XPath leaves them alone). But there is no such connection between these languages and XPath 1.0; it was an earlier language and differs in many respects.

There are two categories of limitation to keep in mind: the restriction from XQuery to XPath for the functions specified in the SQL standard, and the restriction of XPath to version 1.0 for both the standard and the Postgres Pro-specific functions.

#### D.3.1.1. Restriction of XQuery to XPath

Features of XQuery beyond those of XPath include:

- XQuery expressions can construct and return new XML nodes, in addition to all possible XPath values. XPath can create and return values of the atomic types (numbers, strings, and so on) but can only return XML nodes that were already present in documents supplied as input to the expression.
- XQuery has control constructs for iteration, sorting, and grouping.
- XQuery allows declaration and use of local functions.

Recent XPath versions begin to offer capabilities overlapping with these (such as functional-style `for-each` and `sort`, anonymous functions, and `parse-xml` to create a node from a string), but such features were not available before XPath 3.0.

#### D.3.1.2. Restriction of XPath to 1.0

For developers familiar with XQuery and XPath 2.0 or later, XPath 1.0 presents a number of differences to contend with:

- The fundamental type of an XQuery/XPath expression, the *sequence*, which can contain XML nodes, atomic values, or both, does not exist in XPath 1.0. A 1.0 expression can only produce a node-set (containing zero or more XML nodes), or a single atomic value.
- Unlike an XQuery/XPath sequence, which can contain any desired items in any desired order, an XPath 1.0 node-set has no guaranteed order and, like any set, does not allow multiple appearances of the same item.

#### Note

The libxml2 library does seem to always return node-sets to Postgres Pro with their members in the same relative order they had in the input document. Its documentation does not commit to this behavior, and an XPath 1.0 expression cannot control it.

- While XQuery/XPath provides all of the types defined in XML Schema and many operators and functions over those types, XPath 1.0 has only node-sets and the three atomic types `boolean`, `double`, and `string`.
- XPath 1.0 has no conditional operator. An XQuery/XPath expression such as `if ( hat ) then hat/@size else "no hat"` has no XPath 1.0 equivalent.
- XPath 1.0 has no ordering comparison operator for strings. Both `"cat" < "dog"` and `"cat" > "dog"` are false, because each is a numeric comparison of two NaNs. In contrast, `=` and `!=` do compare the strings as strings.

- XPath 1.0 blurs the distinction between *value comparisons* and *general comparisons* as XQuery/XPath define them. Both `sale/@hatsize = 7` and `sale/@customer = "alice"` are existentially quantified comparisons, true if there is any `sale` with the given value for the attribute, but `sale/@taxable = false()` is a value comparison to the *effective boolean value* of a whole node-set. It is true only if no `sale` has a `taxable` attribute at all.
- In the XQuery/XPath data model, a *document node* can have either document form (i.e., exactly one top-level element, with only comments and processing instructions outside of it) or content form (with those constraints relaxed). Its equivalent in XPath 1.0, the *root node*, can only be in document form. This is part of the reason an `xml` value passed as the context item to any Postgres Pro XPath-based function must be in document form.

The differences highlighted here are not all of them. In XQuery and the 2.0 and later versions of XPath, there is an XPath 1.0 compatibility mode, and the W3C lists of [function library changes](#) and [language changes](#) applied in that mode offer a more complete (but still not exhaustive) account of the differences. The compatibility mode cannot make the later languages exactly equivalent to XPath 1.0.

### D.3.1.3. Mappings between SQL and XML data types and values

In SQL:2006 and later, both directions of conversion between standard SQL data types and the XML Schema types are specified precisely. However, the rules are expressed using the types and semantics of XQuery/XPath, and have no direct application to the different data model of XPath 1.0.

When Postgres Pro maps SQL data values to XML (as in `xmlelement`), or XML to SQL (as in the output columns of `xmltable`), except for a few cases treated specially, Postgres Pro simply assumes that the XML data type's XPath 1.0 string form will be valid as the text-input form of the SQL datatype, and conversely. This rule has the virtue of simplicity while producing, for many data types, results similar to the mappings specified in the standard. In this release, an explicit cast is needed if an `xmltable` column expression produces a boolean or double value; see [Section D.3.2](#).

Where interoperability with other systems is a concern, for some data types, it may be necessary to use data type formatting functions (such as those in [Section 9.8](#)) explicitly to produce the standard mappings.

## D.3.2. Incidental limits of the implementation

This section concerns limits that are not inherent in the libxml2 library, but apply to the current implementation in Postgres Pro.

### D.3.2.1. Cast needed for `xmltable` column of boolean or double type

An `xmltable` column expression evaluating to an XPath boolean or number result will produce an “unexpected XPath object type” error. The workaround is to rewrite the column expression to be inside the XPath `string` function; Postgres Pro will then assign the string value successfully to an SQL output column of boolean or double type.

### D.3.2.2. Column path result or SQL result column of XML type

In this release, a `xmltable` column expression that evaluates to an XML node-set can be assigned to an SQL result column of XML type, producing a concatenation of: for most types of node in the node-set, a text node containing the XPath 1.0 *string-value* of the node, but for an element node, a copy of the node itself. Such a node-set may be assigned to an SQL column of non-XML type only if the node-set has a single node, with the string-value of most node types replaced with an empty string, the string-value of an element node replaced with a concatenation of only its direct text-node children (excluding those of descendants), and the string-value of a text or attribute node being as defined in XPath 1.0. An XPath string value assigned to a result column of XML type must be parsable as XML.

It is best not to develop code that relies on these behaviors, which have little resemblance to the spec, and are changed in Postgres Pro 12.

### D.3.2.3. Only `BY VALUE` passing mechanism is supported

The SQL standard defines two *passing mechanisms* that apply when passing an XML argument from SQL to an XML function or receiving a result: `BY REF`, in which a particular XML value retains its node

identity, and `BY VALUE`, in which the content of the XML is passed but node identity is not preserved. A mechanism can be specified before a list of parameters, as the default mechanism for all of them, or after any parameter, to override the default.

To illustrate the difference, if `x` is an XML value, these two queries in an SQL:2006 environment would produce true and false, respectively:

```
SELECT XMLQUERY('$a is $b' PASSING BY REF x AS a, x AS b NULL ON EMPTY);  
SELECT XMLQUERY('$a is $b' PASSING BY VALUE x AS a, x AS b NULL ON EMPTY);
```

In this release, Postgres Pro will accept `BY REF` in an `XMLEXISTS` or `XMLTABLE` construct, but will ignore it. The `xml` data type holds a character-string serialized representation, so there is no node identity to preserve, and passing is always effectively `BY VALUE`.

#### **D.3.2.4. Cannot pass named parameters to queries**

The XPath-based functions support passing one parameter to serve as the XPath expression's context item, but do not support passing additional values to be available to the expression as named parameters.

#### **D.3.2.5. No XML (SEQUENCE) type**

The Postgres Pro `xml` data type can only hold a value in `DOCUMENT` or `CONTENT` form. An XQuery/XPath expression context item must be a single XML node or atomic value, but XPath 1.0 further restricts it to be only an XML node, and has no node type allowing `CONTENT`. The upshot is that a well-formed `DOCUMENT` is the only form of XML value that Postgres Pro can supply as an XPath context item.

---

# Appendix E. Release Notes

The release notes contain the significant changes in each Postgres Pro Enterprise release, with major features and migration issues listed at the top. The release notes do not contain changes that affect only a few users or changes that are internal and therefore not user-visible. For example, the optimizer is improved in almost every release, but the improvements are usually observed by users as simply faster queries.

## E.1. Postgres Pro Enterprise 11.18.2

**Release date:** 2022-12-19

### E.1.1. Overview

This release is based on Postgres Pro Enterprise 11.18.1 and provides the following change:

- Fixed an issue in [pgpro\\_scheduler](#), which could lead to all but one database managers exiting with an error “Scheduler manager XX: cannot find information about self in scheduler\_state” immediately after starting. This oversight could cause `pgpro_scheduler` to work correctly only when used in a single database.

### E.1.2. Migration to Version 11.18.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

#### Important

If you have previously migrated to Postgres Pro Enterprise 11.17.1, or suspect data corruption on your replica, it is strongly recommended that you recreate the replica.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.2. Postgres Pro Enterprise 11.18.1

**Release date:** 2022-12-02

### E.2.1. Overview

This release is based on PostgreSQL 11.18 and Postgres Pro Enterprise 11.17.2. All changes inherited from PostgreSQL 11.18 are listed in [PostgreSQL 11.18 Release Notes](#). As compared with Postgres Pro Enterprise 11.17.2, this version also provides the following changes:

- Added [slru\\_buffers\\_size\\_scale](#) that allows to scale the size of SLRU shared memory buffers. Note that the buffer sizes changed due to this improvement.
- Fixed compatibility of [Section F.22](#) with autonomous transactions.
- Fixed a segmentation fault in `postgres_fdw`, which might have occurred when a query was canceled.
- Improved garbage collection logic. Now percent of garbage is calculated based on file size rounded to 4 kB (typical filesystem block size) instead of raw file size, which prevents frequent defragmentation of small files.
- Fixed an issue with physical replication, which could lead to a replica crash in rare cases. Previously, WAL records on update and init of heap pages did not contain `pd_multi_base` so incorrect `xmax` values could be set.

- Fixed huge selectivity overestimation observed in rare cases, which could result in a sequential scan of a whole relation instead of a quick index scan, so certain queries were executed much more slowly than expected. The issue was due to an oversight in a recent optimization of selectivity estimation.
- Upgraded [mamonsu](#) to version 3.5.2, which provides new features and bugfixes. Notable changes are as follows:
  - Added autovacuum utilization metrics.
  - Added Zabbix macros based on plugin parameters from the configuration file, so that triggers can now be dynamically changed directly in Zabbix without updating the configuration file and restarting mamonsu.
- Upgraded [pg\\_probackup](#) to version 2.5.10, which provides optimizations and bugfixes. Notable changes are as follows:
  - Optimized \*.cfm files backup by truncating trailing zeroes.
  - Fixed an issue with `checkdb --amcheck`, which previously completed with an error when the checked database contained partitioned indexes.
  - Fixed a backup failure on a replica that occurred because the version of the `pg_probackup` agent running there was different from that on the master.
- Upgraded [pgpro\\_scheduler](#) to version 2.8. This version introduces the `schedule.timetable()` function, which returns all the jobs, both scheduled and one-time, within the specified time interval.

### E.2.2. Migration to Version 11.18.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Migration of a cluster with tables larger than 16Tb to Postgres Pro Enterprise versions 11 or 10 is not supported.

If you have previously migrated to Postgres Pro Enterprise 11.12.1 or lower, you must run the `REINDEX` command to rebuild GIN indexes.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.3. Postgres Pro Enterprise 11.17.2

**Release date:** 2022-10-07

### E.3.1. Overview

This release is based on Postgres Pro Enterprise 11.17.1 and provides the following changes:

- Fixed a bug in the logic of epoch shifting. The previous bug fix, which involved delta page replication, might have interfered with another issue, resulting in data corruption. Now full page replication is triggered.
- Fixed a segmentation fault, which could occur on a replica due to inconsistent page fragmentation. During pruning, actions on dead tuples could differ on the primary and the standby upon WAL replay, causing page inconsistency.
- Fixed an issue with queries that could time out due to long lock waits. Previously, index type names were locked in temporary tables during index creation.

### E.3.2. Migration to Version 11.17.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

#### Important

If you have previously migrated to Postgres Pro Enterprise 11.17.1, or suspect data corruption on your replica, it is strongly recommended that you recreate the replica.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.4. Postgres Pro Enterprise 11.17.1

**Release date:** 2022-09-02

### E.4.1. Overview

This release is based on PostgreSQL 11.17 and Postgres Pro Enterprise 11.16.1. All changes inherited from PostgreSQL 11.17 are listed in [PostgreSQL 11.17 Release Notes](#). As compared with Postgres Pro Enterprise 11.16.1, this version also provides the following changes:

- Fixed an issue with a large number of warnings issued during page conversion after the upgrade of Postgres Pro Enterprise 9.6 cluster to the current major version. Now `pd_prune_xid` values of version-9.6 pages are reset to zero.
- Fixed a bug in the logic of epoch shifting, which didn't take into account the `XMAX_INVALID` hint bit of the tuple. Previously, it could lead to a sudden increase of the current transaction ID.
- Resolved an issue that caused an error “duplicate key value violates unique constraint” when indexing a database in multiple threads. Now the chosen name of a type being created for the index gets locked to avoid choosing the same name in a parallel process.
- Resolved an issue in the planner's use of the compound indexes statistics: the optimizer reduced the cost prediction accuracy for a query plan if in the `WHERE` clause of the query, values of different types were compared (for example: `integer` and `numeric`, `text` and `name`). Sometimes, for certain combinations of the compared types and values, the issue could cause a server crash.
- Upgraded [mamonsu](#) to version 3.5.1. Notable changes are as follows:
  - Resolved the security issue of exposing passwords through the configuration file. Only `mamonsu` user can access `agent.conf` now.

- Fixed metrics computation that caused “float division by zero” errors in the `mamonsu STATEMENTS` plugin.
- Upgraded [pg\\_probackup](#) to version 2.5.7, which provides the following new features and bugfixes:
  - Enabled output of logs in the JSON format by adding new logging options.
  - Added an option to explicitly specify the directory where the `restore` command should restore WAL records.
  - Changed the level of detail of logging some messages of `pg_probackup` commands to add user convenience to reading logs.
  - Fixed `pg_probackup` hanging that could occur when the `ControlMaster` option was specified in the SSH `config` file. Now the value of `ControlMaster` is explicitly set to “no”.

## E.4.2. Migration to Version 11.17.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Migration of a cluster with tables larger than 16Tb to Postgres Pro Enterprise versions 11 or 10 is not supported.

If you have previously migrated to Postgres Pro Enterprise 11.12.1 or lower, you must run the `REINDEX` command to rebuild GIN indexes.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.5. Postgres Pro Enterprise 11.16.1

**Release date:** 2022-06-09

### E.5.1. Overview

This release is based on PostgreSQL 11.16 and Postgres Pro Enterprise 11.15.2. All changes inherited from PostgreSQL 11.16 are listed in [PostgreSQL 11.16 Release Notes](#). As compared with Postgres Pro Enterprise 11.15.2, this version also provides the following changes:

- Fixed an issue that could occur when attempting to read a parameter being NULL (including reads when calling `set_config(setting_name, null, is_local)`).
- Changed the algorithm of composite type name generation. This fixes an issue in the code of vanilla PostgreSQL, which strictly limits the number of tables with the same long prefix in names.
- Made the [pg\\_freespacemap](#) `pg_freespace` function display the correct amount of free space on pages for tables in CFS tablespaces. The function is now implemented in C instead of SQL used before.
- Upgraded [pg\\_probackup](#) to version 2.5.6, which provides the following new features and bugfixes as compared to version 2.5.5:
  - Added the `--dry-run` flag to the `catchup` command to allow you to estimate the size of data files to be transferred, but make no changes on disk.
  - Changed the level of detail of logging some `catchup` messages for user convenience of log reading.
  - Fixed a bug that prevented correct rereading of a block after a message “File: ... blknum ... have wrong checksum, try again” was issued.
- Upgraded [PTRACK](#) to version 2.3.0, optimizing PTRACK map loading, which previously in some cases could considerably slow down overall database loading. A substantial speed-up is observed for large-size maps.
- Renamed the [vops](#)-specific `unnest()` function with conflicting definition to `vops_unnest()`.

## E.5.2. Migration to Version 11.16.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Migration of a cluster with tables larger than 16Tb to Postgres Pro Enterprise versions 11 or 10 is not supported.

If you have previously migrated to Postgres Pro Enterprise 11.12.1 or lower, you must run the `REINDEX` command to rebuild GIN indexes.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.6. Postgres Pro Enterprise 11.15.2

**Release date:** 2022-03-22

### E.6.1. Overview

This release is based on Postgres Pro Enterprise 11.15.1 and provides the following change:

- Fixed a bug in the [CFS](#) causing subtle corruption of data in compressed tablespaces at the server startup on Windows after an abnormal termination or when restoring a backup.

### E.6.2. Migration to Version 11.15.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.7. Postgres Pro Enterprise 11.15.1

**Release date:** 2022-03-09

### E.7.1. Overview

This release is based on PostgreSQL 11.15 and Postgres Pro Enterprise 11.14.1. All changes inherited from PostgreSQL 11.15 are listed in [PostgreSQL 11.15 Release Notes](#). As compared with Postgres Pro Enterprise 11.14.1, this version also provides the following changes:

- Increased the number of partitions of the shared buffer mapping hash table to 1024, which can improve performance on multi-core systems.
- Fixed an issue with lazy conversion from 32-bit to 64-bit transaction IDs in read-only transactions or on replicas by enforcing marking pages as subject to full-page writes to WAL. This issue could cause failures to synchronize conversion results to other replicas.
- Fixed an issue with \*.cfm files that were unexpectedly left in compressed tablespaces after dropping a table.
- Fixed segmentation fault, which might have occurred when executing a specific procedure calling pattern while [plan\\_cache\\_lru\\_size](#) was set.
- Fixed the use of multi-column statistics by planner. Previously, when the optimizer estimated the query selectivity using multi-column statistics and the query conditions only included part of the columns involved, the cardinality could be considerably overestimated, so the created plan would be non-optimal.
- Fixed the out-of-memory (OOM) killer settings in system startup files. Previously the OOM score adjustment value was set for all Postgres Pro processes rather than for postmaster only, so when Postgres Pro exhausted all RAM, the OOM killer could start killing irrelevant processes, such as sshd.
- Ended support for outdated operating systems Debian 8 and Astra Linux Smolensk 1.5.
- Upgraded [mamonsu](#) to version 3.4.0. Notable changes are as follows:
  - Added a new `timeout` parameter to the `[zabbix]` section of the mamonsu configuration file. It allows you to set maximum time to wait while connecting to the Zabbix server.
  - Added a new `mamonsu dashboard upload template_name` command, which can be used to upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.
- Upgraded [pg\\_probackup](#) to version 2.5.5, which provides the following new features and bugfixes as compared to the previous included version 2.5.3:

- Added the `--checkunique` option to the `checkdb` command to work together with `--amcheck` and verify unique constraints during logical verification of indexes when the `amcheck` extension is installed in the database and its version supports the verification of unique constraints. Check the [amcheck](#) documentation for whether this verification is supported.
- Fixed an issue that could occur when the source database was not on the timeline 1 and the destination database did not fall behind: `probackup` sanity checks on `catchup` timeline history failed with the error “Destination is not in source timeline history”.
- Fixed the behavior of `catchup` in `DELTA` and `PTRACK` modes. The fixed issue could occur when `pg_probackup` operated remotely via SSH and `--destination-pgdata` was the same as `--source-pgdata`, caused corruption of the source instance (at least the `global/pg_control`, `global/pg_filenode.map` and `base/*/pg_filenode.map` files got deleted) and resulted in the error “Could not open file `/pgwal/test/global/pg_control` for reading: No such file or directory”.

## E.7.2. Migration to Version 11.15.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Migration of a cluster with tables larger than 16Tb to Postgres Pro Enterprise versions 11 or 10 is not supported.

If you have previously migrated to Postgres Pro Enterprise 11.12.1 or lower, you must run the `REINDEX` command to rebuild GIN indexes.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take `PTRACK` backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.8. Postgres Pro Enterprise 11.14.1

**Release date:** 2021-12-08

### E.8.1. Overview

This release is based on PostgreSQL 11.14 and Postgres Pro Enterprise 11.13.1. All changes inherited from PostgreSQL 11.14 are listed in [PostgreSQL 11.14 Release Notes](#). As compared with Postgres Pro Enterprise 11.13.1, this version also provides the following changes:

- Fixed `pg_dump` to handle 64-bit XID statistics correctly, which is important when upgrading Postgres Pro Enterprise using `pg_upgrade`. Previously, values over  $2^{32}$  in XID statistics were incorrectly transferred, which led to the launch of autovacuum to prevent transaction ID wraparound.
- Fixed an issue with an upgrade of Postgres Pro Enterprise 9.6 cluster to the current major version using `pg_upgrade`. Previously, it incorrectly converted free space maps of tables larger than 4 TB.
- Dropped support for the `sr_plan` extension.
- Upgraded `mamonsu` to version 3.1.0. Notable changes are as follows:
  - A new option for `bootstrap` is added. With this option, if `-dbname` is not explicitly specified, its value will be automatically set to the database name defined in the `[postgres]` section of the `mamonsu` configuration file.
  - A critical issue is fixed that could arise when the `bootstrap` step was skipped. In this case, although a user can work with `mamonsu` under superuser permissions, the special `mamonsu` schema is not created, but after creating the auxiliary extension `pg_buffercache` in any other schema, running `mamonsu` resulted in errors `"ERROR: relation "mamonsu.pg_buffercache" does not exist..."`.
- Forbade access to temporary namespaces from `autonomous transactions` to ensure predictable behavior.
- Added support for ALT Linux 10.
- Changed the minimum supported Windows versions to Windows 10 and Windows Server 2012 R2.
- Enforced the size limit of 16TB to non-system tables with non-unique and not covering B-tree indexes to avoid issues with such indexes in extremely large tables.
- Fixed a `pg_probackup` issue with archiving WAL from a directory outside of the data directory. Previously, multi-threaded and batch optimizations of `archive-push` prevented such archiving; now it is possible to archive WAL from any directory, but if it is outside of the data directory, multi-threaded and batch optimizations are automatically turned off.
- Fixed `pg_dumpall` to avoid using an insecure search path.
- Deprecated `WAITLSN` command.
- Leveraged sparse file functionality in Windows for `CFS`, which optimizes on-disk size of `*.cfm` files, up to 1MB each.

## E.8.2. Migration to Version 11.14.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Migration of a cluster with tables larger than 16Tb to Postgres Pro Enterprise versions 11 or 10 is not supported.

If you have previously migrated to Postgres Pro Enterprise 11.12.1 or lower, you must run the `REINDEX` command to rebuild GIN indexes.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run `pg_upgrade` to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.9. Postgres Pro Enterprise 11.13.1

**Release date:** 2021-09-09

### E.9.1. Overview

This release is based on PostgreSQL 11.13 and Postgres Pro Enterprise 11.12.1. All changes inherited from PostgreSQL 11.13 are listed in [PostgreSQL 11.13 Release Notes](#). As compared with Postgres Pro Enterprise 11.12.1, this version also provides the following changes:

- Fixed an issue with handling posting list pages in GIN indexes after upgrading Postgres Pro Enterprise to the current major version. This issue could lead to GIN index corruption that manifested itself in “ERROR: XX000: tuple offset out of range” errors on stand-by servers.
- Added support for Debian 11.
- Upgraded mamonsu to version 3.0, which is incompatible with the previous one. Read [mamonsu Compatibility Considerations](#) to learn what you need to do to continue using the application.
- Fixed an issue with `pgpro_scheduler` that could result in a failure to stop a stand-by server, e.g. with `pg_ctl`.
- Added support for Astra Linux Smolensk 1.7.
- Fixed the behavior of `ALTER TABLE IF EXISTS table RENAME TO table1` command in the case when the source table is missing and the `pg_pathman` extension was loaded. Previously, `ERROR` was returned, and now `NOTICE` is generated, which is how Postgres Pro behaves with no `pg_pathman` extension loaded.
- Upgraded `pg_probackup` to version 2.5.1, which added a new `catchup` command to copy a Postgres Pro instance directly, without using the backup catalog. This allows you to add a new standby server in a parallel mode or to have a fallen-behind standby server “catch up” with master.
- Fixed a bug in the query optimizer, which overestimated the cost of index scan using a unique index. This behavior was observed when between index scans using a unique index and using a non-unique one, the non-unique index was chosen, which resulted in excessive disk accesses and a considerable overall slowdown.
- Implemented I/O buffering in [CFS](#), which can improve performance on HDD.
- Fixed a corner case of incorrect snapshot handling in parallel workers.

### E.9.2. Migration to Version 11.13.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

## Important

If you have previously migrated to Postgres Pro Enterprise 11.12.1 or lower, you must run the `REINDEX` command to rebuild GIN indexes.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.10. Postgres Pro Enterprise 11.12.1

**Release date:** 2021-06-07

### E.10.1. Overview

This release is based on PostgreSQL 11.12 and Postgres Pro Enterprise 11.11.3. All changes inherited from PostgreSQL 11.12 are listed in [PostgreSQL 11.12 Release Notes](#). As compared with Postgres Pro Enterprise 11.11.3, this version also provides the following changes:

- Fixed a bug in the [rum](#) extension which caused phrase search to return less results than expected when the `rum_tsvector_addon_ops` or `rum_tsvector_hash_addon_ops` operator class was used.
- Fixed a bug in B-tree deduplication that could lead to a loss of index entries following a single dead entry, thus breaking the index.
- Optimized writing of empty pages to `*.cfm` files when upgrading a cluster with compressed tablespaces using [pg\\_upgrade](#).
- Removed the `hunspell_ne_np` Hunspell dictionary. If you still need it, use the extension from [github](#).
- Fixed an issue that could lead to a server crash due to dangling pointers to the statistics data when using autonomous transactions.
- Upgraded [PTRACK](#) to use a different algorithm for tracking changed pages. This greatly reduces the number of false positives among the changed pages tracked in the PTRACK map and hence the size of PTRACK backups.
- Fixed a memory leak in B-tree deduplication.

- Implemented [restoration](#) of corrupted WAL data from in-memory WAL buffers. This is controlled by the `wal_sender_check_crc` parameter.
- Removed the legacy `pg_shardman` extension.
- Fixed a bug that caused queries to fail with an error “geqo failed to make a valid plan” after updating statistics with `VACUUM ANALYZE` when `enable_compound_index_stats` was on.
- Dropped support for the [multimaster](#) extension.
- Ended support for Ubuntu 16.04.
- Fixed an issue of installing Postgres Pro on Alt Linux 8.2 SP. For this OS, Postgres Pro now provides a separate package repository, which is different from the repositories of earlier Alt Linux SP versions.
- Upgraded [pg\\_hint\\_plan](#).
- Improved the planner's algorithm of self-join selectivity calculation, which ensures more accurate estimates of the number of rows after joins.
- Upgraded [mamonsu](#) to version 2.7.1.
- Upgraded [pgpro\\_controldata](#) to version 13.2.0.

### E.10.2. Migration to Version 11.12.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

If you are upgrading from Postgres Pro Enterprise versions 11.11.x or lower and take PTRACK backups using `pg_probackup`, retake a full backup after upgrade.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.11. Postgres Pro Enterprise 11.11.3

**Release date:** 2021-04-05

### E.11.1. Overview

This release is based on Postgres Pro Enterprise 11.11.2 and provides the following changes:

- Fixed an issue with an upgrade of Postgres Pro Enterprise 9.6 cluster to the current major version using `pg_upgrade`. Previously, it could crash when processing the free space map of a very large table.
- Fixed the signed integer overflow in `ptrack` that could occur when `ptrack` map data in RAM was saved to disk. Previously, for large-size `ptrack` maps (`ptrack.mapsize > 17200 MB`), this resulted in a “FATAL/ERROR `ptrack checkpoint: stat_buf.st_size != ptrack_map_size XXX != YYY`” error during a checkpoint.
- Fixed building of covering indexes with included columns of type for which the collation is defined in the table. The fixed defect could result in an “ERROR: could not determine which collation to use for string comparison” error during the `ANALYZE` operation on the table, although single columns could be successfully analyzed. To avoid this error in future, after upgrading, rebuild covering indexes built at least with one included column.

## E.11.2. Migration to Version 11.11.3

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run `pg_upgrade` to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

When upgrading from Postgres Pro Enterprise versions 11.11.2 or lower, rebuild covering indexes containing at least one included column of type for which the collation was defined in the table.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.12. Postgres Pro Enterprise 11.11.2

**Release date:** 2021-03-23

### E.12.1. Overview

This release is based on Postgres Pro Enterprise 11.11.1 and provides the following changes:

- Fixed an issue with upgrading Postgres Pro Enterprise 9.6 cluster to the current major version of Postgres Pro Enterprise. Previously, such an upgrade could result in a corrupted free space map and visibility map; the corruption manifested in “could not read block XXX in file ...” errors.
- Fixed incorrect data conversion after Postgres Pro Enterprise cluster upgrade through `pg_upgrade` following a migration from PostgreSQL or Postgres Pro Standard edition. Previously, a cluster repeatedly converted like this would lose its original conversion attribute, which would result in a serious data corruption unless *all the data* was accessed before the second upgrade.

- Added the [log2\\_num\\_lock\\_partitions](#) parameter which allows to change a number of lock partitions. Previously the shared lock tables were always divided into 16 partitions; now this number can be increased up to 256 to prevent performance loss in some special cases.

## E.12.2. Migration to Version 11.11.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.13. Postgres Pro Enterprise 11.11.1

**Release date:** 2021-03-02

### E.13.1. Overview

This release is based on PostgreSQL 11.11 and Postgres Pro Enterprise 11.10.1. All changes inherited from PostgreSQL 11.11 are listed in [PostgreSQL 11.11 Release Notes](#). As compared with Postgres Pro Enterprise 11.10.1, this version also provides the following changes:

- Deprecated the `cfs_compress_small_relations` parameter. Small relations are still compressed by default and will not differ from the bigger ones. Make sure to keep the existing parameter setting intact for the lifetime of your database cluster.
- Fixed a bug in the CFS implementation that resulted in disabling compression for all relations when the `cfs_compress_temp_relations` parameter was set.
- Added the `pg_snapshot_any` function to help superusers explore corrupted databases. See [Section 9.26.11](#) for details.
- Aligned the behavior of the parameters `idle_session_timeout` and `idle_in_transaction_session_timeout` with how they will behave in a future PostgreSQL release. Specifically, the `idle_session_timeout` parameter now applies only when outside a transaction.
- Fixed a bug in the btree compression implementation that could lead to a server crash when processing a tuple deletion in some rare cases.
- Upgraded `pg_probackup` to the latest version 2.4.10. Major improvements over the previously included version 2.4.2 are as follows:

- Incremental restore with `--force` flag now allows you to overwrite the contents of the directory specified by `PGDATA` in case of system ID mismatch. Previously this resulted in an error.
- It is now possible to restore and validate backups from a read-only filesystem.
- In-place merge is now disabled only if the storage format changed.
- Non-exclusive backup locks are implemented, which enables concurrent validate and restore. Backup shared locks are now released at the process exit.
- Streamed WAL segments are now added to the backup filelist on the fly and fsynced to disk at the end of the backup.

See [pg\\_probackup documentation](#) for details.

- Fixed a bug that prevented setting `ptrack.map_size` to values higher than 1024 MB due to `int32` overflow. See [PTRACK](#) for details.
- Fixed a bug in [pgpro\\_scheduler](#) due to which jobs scheduled to run exactly at the start of an hour (but at a two-hour or larger interval) were not executed at all.
- Added [pgpro\\_controldata](#) utility to display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server.
- Fixed the behavior of [pg\\_wait\\_sampling](#) in case of interrupting a client backend that accessed the shared queue. Previously, the `pg_wait_sampling` collector could hang in such cases and block other backends trying to read the `pg_wait_sampling_profile` view.
- Fixed a bug in the [multimaster](#) extension related to monotonic sequences. Now the parameter `multimaster.monotonic_sequences` behaves as documented and provides always increasing sequences across all nodes.

### E.13.2. Migration to Version 11.11.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.14. Postgres Pro Enterprise 11.10.1

**Release date:** 2020-11-30

### E.14.1. Overview

This release is based on PostgreSQL 11.10 and Postgres Pro Enterprise 11.9.1. All changes inherited from PostgreSQL 11.10 are listed in [PostgreSQL 11.10 Release Notes](#). As compared with Postgres Pro Enterprise 11.9.1, this version also provides the following changes:

- Ended support for CentOS 6.
- Fixed a bug in the [pg\\_variables](#) module. Now you can create a variable in a transaction after removal of a variable with the same name.
- Upgraded [mamonsu](#) to version 2.6.2.
- Upgraded [pgbouncer](#) to version 1.15.
- Improved the precision of `pgbench` when the `--default-isolation-level` option is used. The default isolation level is now set in the environment variable `PGOPTIONS` so that TPS values are computed consistently, with or without the `--connect` option.
- Fixed [CFS](#) to dramatically speed up `pg_basebackup` for a database that contains a lot of small tables. Previously, nearly 1 MB of zeroes was produced for each relation to be copied.
- Fixed a bug that permitted duplication of rows in a table with a unique index. Only tables with more than one unique index were prone to this issue. The duplicates could appear if insertions were done under a heavy concurrent load and concurrently with DDL operations on the table that triggered invalidation of the relation cache.
- Fixed a bug in the function for estimating the selectivity by index when evaluating a condition. Previously, the server could crash while executing this function if the type cache invalidation occurred at an unsuitable moment.
- Updated [pgpro\\_scheduler](#):
  - Now `pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a master server. Previously it didn't work on a standby server either and besides generated a lot of error messages.
  - Enhanced the scheduling scale used by `pgpro_scheduler` — jobs can now be scheduled to a precision of seconds. Also some predefined keywords can now be used instead of `crontab` strings.
- Updated [multimaster](#):
  - Increased the maximum length of a transaction identifier that is specified in `PREPARE TRANSACTION`. Now the identifier can be up to 200 bytes long, while previously it was limited to 31 bytes.
  - Fixed a bug that could lead to the `mtm-logrep-receiver` process crash in case of failure when starting a dynamic worker. This failure could occur if the `max_worker_processes` parameter was not increased appropriately.
- The use of `pg_upgrade` for upgrading a PostgreSQL or Postgres Pro Standard instance to Postgres Pro Enterprise 11 is no longer supported. If you need to upgrade from these versions, use a `dump/restore`.

### E.14.2. Migration to Version 11.10.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and `POSIX` regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.15. Postgres Pro Enterprise 11.9.1

**Release date:** 2020-08-27

### E.15.1. Overview

This release is based on PostgreSQL 11.9 and Postgres Pro Enterprise 11.8.1. All changes inherited from PostgreSQL 11.9 are listed in [PostgreSQL 11.9 Release Notes](#). As compared with Postgres Pro Enterprise 11.8.1, this version also provides the following changes:

- Disabling [password reuse](#) now correctly works with SCRAM authentication. Previously SCRAM-encrypted password was reused even when it was not supposed to.
- Fixed bug in `pgpro_scheduler` that prevented stopping of the running jobs on `schedule.stop()`.
- Fixed the GUC parameter group naming. A `Compressed File System` parameter group name has been omitted previously which caused other group names to be shifted.
- Improved the `rum` extension:
  - Improved full text search for `tsvector` values with the lexeme weights specified. When executing queries with the weight-based constraints, the index search results do not need to be rechecked in table, so these queries perform much faster.
  - Fixed the error which causes result loss when the negation operator is used in such queries.
- Removing multimaster temporary schemas (`mtm_tmp_X_Y`) that can be left over after a node crash. This ensures that such orphaned schemas are not accumulated on crashes.
- Removed CFS map recovery procedure executed at server start. It could create race condition and did not provide any benefit.
- Introduced new multimaster extension version to enable functionality implemented in Postgres Pro Enterprise version 11.8.1. Previously this functionality was not enabled on Postgres Pro Enterprise upgrade.
- Upgraded `pg_probackup` to latest version 2.4.2:
  - New options and flags can now be used to add flexibility to `delete`, `backup`, `restore`, `archive-push` and `set-backup` commands.
  - Incremental restore and support for multi-timeline incremental chains have been added.
  - Postgres Pro parameters `slot_name` and `primary_conninfo` can be used during restore.
  - `archive-push` and `archive-get` commands considerably reworked.
  - Improvements have been achieved in speed and memory consumption.

See [pg\\_probackup documentation](#) for details.

- Ended support for PTRACK versions lower than 2.0 (1.5 - 1.7) since they contain a critical bug that can cause silent corruption in PTRACK backups that were taken under load. PTRACK 1.x API is retained for backward compatibility although all the functionality is no longer available. It is recommended that you avoid restoring PTRACK backups taken earlier, but if such a need arises, validate any restored cluster instance using the command: `pg_probackup checkdb --amcheck`.
- Added the optional `tune` argument to the `pg-setup initdb` command. This argument allows you to choose one of the predefined customized configurations for your database cluster.
- Ended support for SUSE Linux Enterprise Server 11.
- Fixed race conditions in BRIN index that caused errors:
  - "failed to find parent tuple for heap-only tuple ...".

The error could occur when the `brin_summarize_new_values()` function and HOT updates were executed simultaneously in concurrent transactions.
  - "corrupted BRIN index: inconsistent range map".

The error could occur when BRIN index's desummarization and a bitmap scan were executed simultaneously in concurrent transactions.
- Upgraded mamonsu for Linux systems to version 2.5.1. Now it is based on Python 3. Version 2.3.4 is still provided for Windows systems.

## E.15.2. Migration to Version 11.9.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run `pg_upgrade` to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.16. Postgres Pro Enterprise 11.8.1

**Release date:** 2020-05-28

### E.16.1. Overview

This release is based on PostgreSQL 11.8 and Postgres Pro Enterprise 11.7.2. All changes inherited from PostgreSQL 11.8 are listed in [PostgreSQL 11.8 Release Notes](#). As compared with Postgres Pro Enterprise 11.7.2, this version also provides the following changes:

- Fixed an issue with an infinite loop that could lead to consuming all the available memory while planning join operations with multiple `IN` conditions.
- Fixed an issue that could lead to server failure if autovacuum tried to access a manually dropped temporary namespace.
- Fixed an issue that could lead to losing transactional consistency if multiple autonomous transactions were in use.
- Enabled index replacement for primary key and exclusion constraints using the `ALTER CONSTRAINT ... USING INDEX` clause of the `ALTER TABLE` command; previously, this functionality was supported only for unique constraints. Besides, index compatibility checks performed during such replacements have been refined.
- Updated `CFS` to allow changing the `cfs_gc_threshold` parameter for the current session. Now you can temporarily set it to a smaller value if you would like to manually defragment a relation with a smaller percent of garbage than is currently allowed.
- Fixed a memory leak that could occur during join operations if they required estimating multiple query execution paths for complex queries.
- Added the `--no-data-checksums` option for `initdb` to allow initializing Postgres Pro clusters with checksums disabled.
- Optimized writing of empty pages to `*.cfm` files in `base backups`.
- Added support for Oracle Linux 8.
- Added support for ALT Linux 8 SP.
- Added support for Ubuntu 20.04.
- Added the `plpython3` package for Rosa Enterprise Linux Server 7, ROSA COBALT (server edition) based on Rosa platform 7, and AlterOS 7.5 distributions where it was previously missing. Now it is available on all supported platforms except SLES 11.
- Upgraded several libraries provided with Postgres Pro on Windows. Now the following libraries are used: OpenSSL 1.1.1g, libzstd 1.4.4, gettext 0.20.2, libiconv 1.16, libxml2 2.9.9, and libxslt 1.1.32. The ICU library has been upgraded from version 56.1 to 56.2.
- Updated the `multimaster` extension. Now it provides the `mtm.check_query(query_text)` function for checking data consistency between cluster nodes. For details, see [Section F.30.4.6](#).
- Updated `amcheck` to correctly handle B-tree indexes that use deduplication.
- Upgraded `pgpro_scheduler` to version 2.6. This version introduces several fixes and enhancements, including the following:
  - Running DDL commands within scheduled tasks does not cause server failure anymore.
  - `pgpro_scheduler` now starts scheduled jobs once a background worker becomes available if there were not enough workers to start the job on time.
  - The implementation of cron parser has been fully reworked.
- Upgraded `pageinspect` to version 1.6 to correctly handle 64-bit transaction IDs.
- Updated `vops` to provide an automated way of generating and accessing vectorized data. For details, see [Section F.68.5.5](#).
- Upgraded `pg_pathman` to version 1.5.11 to avoid server failure when trying to access child partitions without the required permissions while parent table access is allowed. This issue could previously occur when using `pg_pathman` with Postgres Pro 11.7.1 or higher.

## E.16.2. Migration to Version 11.8.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.17. Postgres Pro Enterprise 11.7.2

**Release date:** 2020-04-07

### E.17.1. Overview

This release is based on Postgres Pro Enterprise 11.7.1 and provides the following changes:

- Fixed a memory leak that could occur when vacuuming tables with non-unique B-tree indexes.

### E.17.2. Migration to Version 11.7.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. When upgrading from these versions, run [pg\\_upgrade](#) to fix this issue, or manually correct `pg_proc` entries for these functions in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions if you are upgrading from lower versions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.18. Postgres Pro Enterprise 11.7.1

**Release date:** 2020-02-28

### E.18.1. Overview

This release is based on PostgreSQL 11.7 and Postgres Pro Enterprise 11.6.2. All changes inherited from PostgreSQL 11.7 are listed in [PostgreSQL 11.7 Release Notes](#). As compared with Postgres Pro Enterprise 11.6.2, this version also provides the following changes:

- Added the [enable\\_compound\\_index\\_stats](#) configuration parameter to control the use of compound indexes statistics for selectivity estimation.
- Increased the maximum value of the [track\\_activity\\_query\\_size](#) parameter to 1MB. In vanilla PostgreSQL, this change is targeted for version 13.
- Updated [CFS](#) to enhance compression functionality:
  - The `cfs_compress_small_relations` parameter controls whether small tables are compressed. It may be useful to turn off this setting for databases with many relations smaller than 1GB to avoid overhead.
- The built-in [connection pooler](#) has been improved. As compared to the previous version, the following changes have been introduced:
  - The [dedicated\\_users](#) parameter enables you to specify one or more users that can have a separate backend for each connection even if connection pooling is enabled.
  - Pooled backends can now serve multiple users, so all connections to a particular database use a common pool.
- Improved stability of [multimaster](#) extension:
  - It is recommended to use `multimaster` in a three-node configuration, where one node is a referee. For details on how to set up a cluster with a referee, see [Section F.30.3.3](#).
  - Fixed an issue with WAL bloating by purging synchronization points of the dropped node and fixing the calculation of the minimal required LSN. Previously, it could occur when dropping a cluster node.
  - Fixed an issue with returning a node to the cluster after this node has been offline for a long time.
  - Forced synchronization point upon `multimaster` initialization to handle the case when a crash happens before the first synchronization.
- Fixed planner's optimization to correctly take into account similar `OR` clauses if they reference columns that are different, but have the same position in different indexes.
- Improved query performance with row-level security policy enabled by correctly marking numeric comparison functions as leakproof.
- Fixed self join removal functionality to achieve better stability.
- Optimized execution of queries with Materialize nodes that return nothing; now such nodes are called only once and skipped in all the subsequent runs.
- Fixed the `mchar` extension to correctly handle the `ESCAPE` clause in `SIMILAR TO` regular expressions.
- Upgraded `pg_probackup` to version 2.2.7.
- Upgraded `mamonsu` to version 2.4.4.

### E.18.2. Migration to Version 11.7.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

While functions `numeric_eq`, `numeric_ne`, `numeric_gt`, `numeric_ge`, `numeric_lt`, and `numeric_le` are actually leakproof, they were not marked as such in Postgres Pro Enterprise 11.6.1 or lower, which could lead to incorrect query optimization. In particular, it negatively affected query execution if row-level security policy was in use. Version 11.7.1 repairs this issue for new installations by correcting the initial catalog data, but existing installations will still have incorrect markings unless you update `pg_proc` entries for these functions. You can run [pg\\_upgrade](#) to upgrade your server instance to a version containing the corrected initial data, or manually correct these entries in each database of the installation using the `ALTER FUNCTION` command. For example:

```
ALTER FUNCTION pg_catalog.numeric_eq LEAKPROOF
```

Version 11.7.1 also fixes `SIMILAR TO` and POSIX regular expressions that use character classes for ICU collations, so you may need to check for objects that use such regular expressions.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.19. Postgres Pro Enterprise 11.6.2

**Release date:** 2019-12-27

### E.19.1. Overview

This release is based on Postgres Pro Enterprise 11.6.1 and provides several improvements for multi-master, including the following:

- Fixed an issue introduced in Postgres Pro Enterprise 11.6.1 that did not allow to upgrade multimaster to a newer version. After installing Postgres Pro Enterprise 11.6.2, you need to restart all nodes of your multimaster cluster.

### E.19.2. Migration to Version 11.6.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.20. Postgres Pro Enterprise 11.6.1

**Release date:** 2019-12-13

### E.20.1. Overview

This release is based on PostgreSQL 11.6 and Postgres Pro Enterprise 11.5.4. All changes inherited from PostgreSQL 11.6 are listed in [PostgreSQL 11.6 Release Notes](#). As compared with Postgres Pro Enterprise 11.5.4, this version also provides the following changes:

- Added support for ALT Linux 9.
- Modified the implementation of ICU default collations to ensure that the server can be started after the ICU library has been upgraded. For details, see the migration instructions below.
- Forbade access to tables that belong to partition hierarchies in which both `pg_pathman` and standard PostgreSQL inheritance have been used for partitioning. Mixing different partitioning mecha-

nisms in a single table hierarchy is unsupported and should have never been attempted. Previously, you could get duplicated query results from such table hierarchies.

- Enabled bulk page allocation for indexes.
- Fixed handling of temporary tables by autonomous transactions.
- Fixed handling of NULL distance values when using k-NN search with SP-GiST.
- Fixed an issue caused by removing self-joins from plans when using any condition other than = in the join operation.
- Fixed incorrect memory allocation by optimizer in a background process.
- Reduced memory consumption when using ICU collations.
- Reduced planner's memory consumption and sped up `EXPLAIN ANALYZE` for queries with multiple `JOIN` clauses.
- Improved stability of the `pg_query_state` module.
- Update `pgpro_scheduler`:
  - Changing `pgpro_scheduler` parameters on the fly does not cause server failures anymore.
  - `pgpro_scheduler` stability has been improved for several other corner cases.
- Updated `multimaster`:
  - Added support for temporary tables.
  - Added support for updating `enum` values.
  - Fixed an issue that caused WAL bloating.
  - Fixed handling of node ID sequences when adding or removing cluster nodes.
  - Fixed connection logic in `multimaster` to allow a node to return to the cluster if the domain name of this node can be resolved to different IP addresses.
- Updated the `mamonsu` module to version 2.4.1. You can now convert all system and Postgres Pro metrics definitions provided by `mamonsu` to the format supported by the native Zabbix agent.
- Upgraded `pgbouncer` to version 1.11.0.
- Upgraded `pg_probackup` to version 2.2.5.

## E.20.2. Migration to Version 11.6.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

Starting from Postgres Pro Enterprise 11.6.1, the ICU library upgrade does not interfere with the server start. Before connecting to a database using ICU as the default collation, Postgres Pro compares this collation version to the one provided by the ICU library and displays a warning if the collation versions do not match; you may need to rebuild the objects that depend on the default collation if you think the collation change may affect the sort order of your data. To suppress these warnings, you can use the `ALTER COLLATION "default" REFRESH VERSION` command, as explained in [ALTER COLLATION](#).

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.21. Postgres Pro Enterprise 11.5.4

**Release date:** 2019-10-08

### E.21.1. Overview

This release is based on Postgres Pro Enterprise 11.5.3 and provides several improvements:

- Added support for CentOS 8.
- The expression comparison function has been reworked to fix bugs and improve support in the future.

## E.21.2. Migration to Version 11.5.4

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.22. Postgres Pro Enterprise 11.5.3

**Release date:** 2019-09-17

### E.22.1. Overview

This release is based on Postgres Pro Enterprise 11.5.2 and provides several improvements:

- Added support for Python 3 on SLES 12/15 and JIT on SLES 15.
- Improved optimizer performance on simple queries.
- Fixed assorted bugs in planner that could cause server failures.
- Ensured that `pg_visibility` is compatible with 64-bit transaction IDs.

### E.22.2. Migration to Version 11.5.3

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.23. Postgres Pro Enterprise 11.5.2

**Release date:** 2019-08-23

### E.23.1. Overview

This release is based on Postgres Pro Enterprise 11.5.1 and provides several improvements for multi-master, including the following:

- Fixed an issue in multimaster that could affect replication of statements that report zero modified rows in command tag, but have modified some rows, which is possible if a common table expression (CTE) is used.

### E.23.2. Migration to Version 11.5.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.24. Postgres Pro Enterprise 11.5.1

**Release date:** 2019-08-14

## E.24.1. Overview

This release is based on PostgreSQL 11.5 and Postgres Pro Enterprise 11.4.2. All changes inherited from PostgreSQL 11.5 are listed in [PostgreSQL 11.5 Release Notes](#). As compared with Postgres Pro Enterprise 11.4.2, this version also provides the following changes:

- Added support for Debian 10.
- Added support for Red Hat Enterprise Linux 8.
- Added `-z/-Z` options to [postgres](#) that check compatibility between the specified cluster and the current postgres binary without starting the cluster.
- Fixed a memory allocation issue that could occur if the [plan\\_cache\\_lru\\_size](#) feature was used, which is enabled in Postgres Pro Enterprise by default.
- Fixed `VACUUM` logic for truncating multixact members as required for 64-bit transaction and multixact IDs. It resolves a bloating issue that could affect the `pg_multixact` directory.
- Backported an optimization for the `PostmasterIsAlive()` check. On Linux systems, backends now use signals to determine that postmaster has died. In particular, it fixes an issue with `pg_wal` bloating and high CPU load when logical replication with multiple publications and subscriptions is used. In vanilla PostgreSQL, this optimization appears in version 12.
- Improved handling of dead tuples for B-tree indexes that perform key deduplication.
- Improved planning accuracy for queries with `OR` clauses. Now sorting is performed correctly for such queries.
- Fixed implementation of greater than (`>`) and not equal to (`<>`) operators for the `jsquery` type.
- Fixed a deadlock issue in the `pg_wait_sampling` module. Previously, a deadlock could occur if clients got disconnected before receiving the requested statistics on wait events. Now statistics collector releases the exclusive lock in such cases and logs the following message: `pg_wait_sampling collector: receiver of message queue has been detached`.
- Improved the multimaster module:
  - Added support for autonomous transactions on multi-master clusters (see [Chapter 16](#)).
  - Fixed an issue in multimaster that resulted in a rollback of the first transaction on a backend if this transaction set repeatable read or serializable isolation level. This issue manifested itself in the following error message: `ERROR: SET TRANSACTION ISOLATION LEVEL must be called before any query`.
  - Fixed an issue in the `mtm.make_table_local()` function that could cause hanging and interfere with node recovery.

## E.24.2. Migration to Version 11.5.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.25. Postgres Pro Enterprise 11.4.2

**Release date:** 2019-07-23

### E.25.1. Overview

This release is based on PostgreSQL 11.4 and provides the following improvements for multimaster:

- Fixed an issue in multimaster that resulted in a rollback of the first transaction on a backend if this transaction set repeatable read or serializable isolation level. This issue manifested itself in the fol-

lowing error message: `ERROR: SET TRANSACTION ISOLATION LEVEL must be called before any query.`

- Added support for partitioning functions provided by `pg_pathman`.

## E.25.2. Migration to Version 11.4.2

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.26. Postgres Pro Enterprise 11.4.1

**Release date:** 2019-07-04

### E.26.1. Overview

This release is based on PostgreSQL 11.4 and Postgres Pro Enterprise 11.2.1. All changes inherited from PostgreSQL 11.4 are listed in [PostgreSQL 11.4 Release Notes](#). As compared with Postgres Pro Enterprise 11.2.1, this version also provides the following changes:

- Added support for SUSE Linux Enterprise Server 12 SP3.
- Added support for Astra Linux Orel 2.12.
- Added support for Rosa Enterprise Linux Server 7 and ROSA COBALT 7 (server edition). The previous versions of these operating systems are no longer supported.
- Improved selectivity estimation for queries with `IN` operations, as well as with conditions referencing columns that appear in wider multi-column indexes.
- Updated `pg_pathman` module to version 1.5.8. As compared to version 1.5.5 provided in the previous Postgres Pro releases, the following enhancements were introduced:
  - Fixed handling of tables with multilevel partitioning. Previously, `SELECT FOR SHARE` and `SELECT FOR UPDATE` commands for such tables could return the following error: `ERROR: variable not found in subplan target lists`.
  - Enhanced `pg_pathman` stability.
- Updated `pg_probackup` module to version 2.1.3. As compared with version 2.0.26, it offers the following major improvements:
  - Backup and restore of a remote Postgres Pro instance via SSH.
  - Merging incremental backups with their expired parent backups to satisfy retention policy.
  - Backing up files and directories located outside of Postgres Pro data directory, such as configuration or log files.
  - The `checkdb` command for validating all data files in the Postgres Pro instance and logical verification of indexes using [amcheck](#).

For a full list of changes, see [pg\\_probackup Wiki](#).

- Improved `pgpro_scheduler` extension:
  - Added the `schedule.auto_enabled` configuration parameter that specifies whether to enable `pgpro_scheduler` at the server start. By default, `pgpro_scheduler` is not automatically restarted if you reload the server.
  - Added the `schedule.is_enabled()` that allows to check whether `pgpro_scheduler` is currently running. The `schedule.enabled` configuration parameter that could previously serve this purpose is now deprecated.
- Updated `multimaster` extension:

- Added support for `pg_pathman` declarative syntax. Partitioning using `pg_pathman` functions is not yet supported by `multimaster`.

## E.26.2. Migration to Version 11.4.1

If you are upgrading from a Postgres Pro Enterprise release based on the same PostgreSQL major version, it is enough to install the new version into your current installation directory.

To migrate from PostgreSQL, as well as Postgres Pro Standard or Postgres Pro Enterprise based on a previous PostgreSQL major version, see the [migration instructions for version 11](#).

## E.27. Postgres Pro Enterprise 11.2.1

**Release date:** 2019-05-07

### E.27.1. Overview

This release is based on Postgres Pro Enterprise 10.7.1 and PostgreSQL 11.2. It includes all the new features introduced in PostgreSQL 11, as well as bug fixes implemented in PostgreSQL 11.1 and 11.2. For their detailed description, see [PostgreSQL 11](#), [PostgreSQL 11.1](#), and [PostgreSQL 11.2](#) Release Notes, respectively. As compared with Postgres Pro Enterprise 10.7.1, this version adds the following new features:

- Implemented an experimental built-in connection pooler that can limit the number of backends when working with multiple clients, without imposing restrictions on using session configuration parameters, prepared statements, or temporary tables. See [Chapter 34](#) for details.
- Added the *autoprepere* mode that allows to implicitly prepare frequently used statements, thus eliminating the cost of their compilation and planning on each subsequent execution. For details, see [Section 14.6](#).
- Added support for changing configuration of other sessions, which allows to switch on debug messages to trace sessions with unexpected behavior. See [Section 9.26.1](#) for details.
- Enabled replacement of a constraint index without dropping this constraint using the `ALTER CONSTRAINT ... USING INDEX` clause of the [ALTER TABLE](#) command.
- Updated Postgres Pro Enterprise default configuration to use declarative partitioning syntax provided by Postgres Pro core instead of the `pg_pathman` implementation, which is used in Postgres Pro Enterprise 10 by default. You can change this setting using the [partition\\_backend](#) parameter, if required.
- Improved usability of the `multimaster` extension:
  - Now `multimaster` uses only native Postgres Pro connections between nodes, without setting up an extra communication channel on a different TCP port. Hence connection strings do not need the `arbiter_port` option anymore, and `multimaster.arbiter_port` configuration parameter has been removed. The `multimaster.use_rdma` parameter is also deleted since `multimaster` can now use all connection types supported by Postgres Pro without any additional settings.
  - Cluster configuration is now stored inside the database instead of configuration files. That allows to assign node IDs automatically and avoid manual editing of configuration files on all cluster nodes when adding or dropping a node. Therefore, `multimaster.conn_strings` and `multimaster.node_id` have been removed. You can use the `mtm.init_cluster()` function to update cluster configuration on all nodes.
  - Tables without a primary key are now always replicated by default, so the `multimaster.ignore_tables_without_pk` configuration parameter has been removed. You can still stop replicating a table using the `mtm.make_table_local()` function.
  - Automatic deletion of a lagged replication slot is no longer happening as it caused more problems than it solved. To drop replication slots for a node, you have to explicitly call the `mtm.drop_node()` function.

- The `mtm.major_node` configuration parameter has been removed as redundant since the same behavior can be achieved in the referee mode.
- The `multimaster.max_nodes` is no longer required to change the cluster configuration. The `mtm.add_node()` does all the necessary work.
- Several ways of dropping/adding nodes have been unified into a single mechanism that is now accessible through functions `mtm.add_node()/mtm.drop_node()`.
- Monitoring views have been redesigned, and cluster information is now accessible via `mtm.status()` and `mtm.nodes()` functions. The `mtm.collect_cluster_info()`, `mtm.get_cluster_state()`, and `mtm.get_nodes_state()` functions have been deleted.
- The `mtm.copy_table` and `mtm.broadcast_table` functions have been removed as redundant.
- Added support for Just-in-Time (JIT) compilation on Debian and Ubuntu systems, Astra Linux 1.6, ALT Linux 8, and CentOS 7. To use this functionality, you must install a separate JIT package and set up your environment as explained in [Chapter 17](#). To learn more about JIT, see [Chapter 32](#).
- Added support for SUSE Linux Enterprise Server 15 and AlterOS 7.5.
- Added PL/Python packages for Python 3 on SUSE Linux Enterprise Server 12.1, CentOS 6/7, Red Hat Enterprise Linux 6/7, and Oracle Linux 6/7.
- Modified ICU usage specifics: ICU collation version is no longer stored in the cluster and therefore it is not checked when connecting to a database. For upgrade implications of this change, see [Section E.27.2](#).
- Accelerated index creation and minimized undesired eviction of relation pages from shared buffers while an index is being built.
- Updated planner/optimizer to improve planning speed and accuracy for several query types:
  - When estimating the sorting cost, the planner now takes into account comparison complexity, field width, and the number of comparison function calls required for each column, which results in fewer estimation errors.
  - For queries with several columns in the `GROUP BY` clause, it is now possible to choose the order of columns when sorting the data if it does not affect query accuracy. The more unique values the first sorted column contains, the less sorting is required for other columns. If all values in one of the columns are unique, it may be enough to sort data by that column only. The planner can also take advantage of the existing sorting results of index scans or the `ORDER BY` clause.
  - If all tables to be joined have indexes, they are now used to estimate the number of rows in the joined result.
  - Self-joins are now eliminated from plans if it does not affect query results.
- Fixed an issue in index search that caused a slowdown when using complex `jsonquery` values.
- Improved selectivity estimation for indexes on boolean columns.
- Improved stability of [autonomous transactions](#).
- Added `pg_recovery_settings` view that displays the current recovery settings stored in the `recovery.conf` file.

All the Postgres Pro features included into Postgres Pro Enterprise 10.7.1 have been ported. You can get an overview of all the main Postgres Pro enhancements over vanilla PostgreSQL in [Section 2](#).

### Note

Covering indexes have been committed to PostgreSQL 11, so Postgres Pro now inherits their modified implementation. If you have been using covering indexes in the previous versions of Postgres Pro Enterprise, you have to rebuild them after the upgrade.

## E.27.2. Migration to Version 11

To migrate to Postgres Pro Enterprise 11 from PostgreSQL or Postgres Pro Standard, you should perform a dump/restore using [pg\\_dumpall](#). [pg\\_upgrade](#) utility can only be used when upgrading from lower versions of Postgres Pro Enterprise. Before the upgrade, remember to install the latest available minor version of your product if it is based on a previous major version of PostgreSQL.

When migrating from PostgreSQL or Postgres Pro Standard, make sure to pay special attention to implementation specifics of [64-bit transaction IDs](#). If you have used explicit casts to 32-bit integers when handling transaction IDs, you have to replace them with casts to `bigint` since 64-bit transaction IDs are of the `bigint` type.

### Note

To avoid conflicts on Linux systems, do not use the `postgrespro-ent-11` package to install the new Postgres Pro binaries. Use the individual packages instead. In this case, server autostart needs to be enabled manually, if required. For details on the available packages and installation instructions, see [Chapter 17](#).

If you choose to run `pg_upgrade`, make sure to initialize the new database cluster with compatible parameters. In particular, pay attention to the provider of the default collation and the [checksum](#) settings in the cluster you are migrating from. If `pg_upgrade` creates any SQL files in its current directory, run these files to complete the upgrade.

If you are opting for a dump/restore, do not forget to use the `--add-collprovider` option to correctly choose the provider for the default collation of the migrated database.

To find out the default collation and its provider in the original cluster, see the `datcollate` value for the `template0` database in the [pg\\_database](#) catalog. If you are upgrading from a version where provider of the default collation is not specified, use `libc` provider if upgrading from vanilla PostgreSQL, and omit the provider if upgrading from earlier versions of Postgres Pro.

Besides, note the following collation-related upgrade specifics described below.

On Windows, Postgres Pro installations could contain databases with default collations provided by ICU, where the name of the database default collation used a syntactically correct BCP 47 language tag format, but had a wrong language code or other parameters, which invalidated the database default collation name for ICU.

If this issue affects the `template0` database, you will get the following error message when trying to initialize the cluster with the same collation: `failed to get the canonical name for collation locale`. In this case, you can only use dump/restore for upgrade, specifying a valid locale for the selected collation provider.

If this issue affects other databases, you will get the same error message when Postgres Pro tries to create these databases with invalid collation in the new cluster. In this case, you can try the following:

1. Make a dump of the database using `pg_dump`; it is required to use `--create` and `--format=plain` options.
2. Change the provider for the default collation of the database in the dump file from `'@icu'` to `'@libc'`.
3. In `psql`, restore the modified dump to complete the upgrade. This operation may fail if any constraints depending on the database collations are violated. In this case, you can try resolving the issues manually or call the support team.

In some corner cases, using dump/restore could lead to invalid constraints in the restored databases. For example:

- If the installation of Postgres Pro 9.6 or lower contained any indexes or constraints depending on collations other than the default collation of the database, `C`, or `POSIX` in databases with multibyte

encodings, indexes and constraints in such databases could become inconsistent when these databases are migrated to Postgres Pro 10 or higher. On Windows, this situation can also happen if the database with a multibyte encoding contained any indexes or constraints depending on the default collation with a verbose name, such as `"Russian_Russia[.encoding]"` or `"English_United States[.encoding]"`.

- For upgrades from Postgres Pro 10, if the cluster has no information about the ICU library version, the ICU collation versions are checked to ensure that indexes and constraints remain valid after the upgrade. However, for clusters that contain databases with default ICU collations but have no information about the ICU library version and/or its collation versions, it is impossible to check that the current version of Postgres Pro uses the same version of the ICU library.
- On Windows, in Postgres Pro 10 clusters with default collations provided by ICU, the ICU collation locale may not match the corresponding `libc` collation locale.

If you use `pg_upgrade`, it declares such indexes and constraints invalid and creates `reindex_text_indexes.sql` and `validate_text_constraints.sql`, respectively. You have to run these files to complete the upgrade.

For other upgrade requirements imposed by vanilla PostgreSQL, see [Section E.46](#).

## E.28. Release 11.18

**Release date:** 2022-11-10

This release contains a variety of fixes from 11.17. For information about new features in major release 11, see [Section E.46](#).

### E.28.1. Migration to Version 11.18

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.14, see [Section E.32](#).

### E.28.2. Changes

- Fix `VACUUM` to press on if an attempted page deletion in a btree index fails to find the page's parent downlink (Peter Geoghegan)

Rather than throwing an error, just log the issue and continue without deleting the empty page. Previously, a buggy operator class or corrupted index could indefinitely prevent completion of vacuuming of the index, eventually leading to transaction wraparound problems.

- Fix handling of `DEFAULT` tokens that appear in a multi-row `VALUES` clause of an `INSERT` on an updatable view (Tom Lane)

This oversight could lead to “cache lookup failed for type” errors, or in older branches even to crashes.

- Disallow rules named `_RETURN` that are not `ON SELECT` (Tom Lane)

This avoids confusion between a view's `ON SELECT` rule and any other rules it may have.

- Repair rare failure of `MULTIEXPR_SUBLINK` subplans in inherited updates (Tom Lane)

Use of the syntax `UPDATE tab SET (c1, ...) = (SELECT ...)` with an inherited or partitioned target table could result in failure if the child tables are sufficiently dissimilar. This typically manifested as failure of consistency checks in the executor; but a crash or incorrect data updates are also possible.

- Fix incorrect matching of index expressions and predicates when creating a partitioned index (Richard Guo, Tom Lane)

While creating a partitioned index, we try to identify any existing indexes on the partitions that match the partitioned index, so that we can absorb those as child indexes instead of building new ones. Matching of expressions was not done right, so that a usable child index might be ignored, leading to creation of a duplicative index.

- Avoid flattening `FROM`-less subqueries when the outer query has grouping sets (Tom Lane)

This oversight could lead to assertion failures or planner errors such as “variable not found in sub-plan target list”.

- Prevent WAL corruption after a standby promotion (Dilip Kumar, Robert Haas)

When a PostgreSQL instance performing archive recovery (but not using standby mode) is promoted, and the last WAL segment that it attempted to read ended in a partial record, the instance would write an invalid WAL segment on the new timeline.

- Fix mis-ordering of WAL operations in fast insert path for GIN indexes (Matthias van de Meent, Zhang Mingli)

This mistake is not known to have any negative consequences within core PostgreSQL, but it did cause issues for some extensions.

- Fix bugs in logical decoding when replay starts from a point between the beginning of a transaction and the beginning of its subtransaction (Masahiko Sawada, Kuroda Hayato)

These errors could lead to assertion failures in debug builds, and otherwise to memory leaks.

- Prevent examining system catalogs with the wrong snapshot during logical decoding (Masahiko Sawada)

If decoding begins partway through a transaction that modifies system catalogs, the decoder may not recognize that, causing it to fail to treat that transaction as in-progress for catalog lookups.

- Accept interrupts in more places during logical decoding (Amit Kapila, Masahiko Sawada)

This ameliorates problems with slow shutdown of replication workers.

- Avoid crash after function syntax error in replication workers (Maxim Orlov, Anton Melnikov, Masahiko Sawada, Tom Lane)

If a syntax error occurred in a SQL-language or PL/pgSQL-language `CREATE FUNCTION` or `DO` command executed in a logical replication worker, the worker process would crash with a null pointer dereference or assertion failure.

- Fix handling of read-write expanded datums that are passed to SQL functions (Tom Lane)

If a non-inlined SQL function uses a parameter in more than one place, and one of those functions expects to be able to modify read-write datums in place, then later uses of the parameter would observe the wrong value. (Within core PostgreSQL, the expanded-datum mechanism is only used for array and composite-type values; but extensions might use it for other structured types.)

- In Snowball dictionaries, don't try to stem excessively-long words (Olly Betts, Tom Lane)

If the input word exceeds 1000 bytes, return it as-is after case folding, rather than trying to run it through the Snowball code. This restriction protects against a known recursion-to-stack-overflow problem in the Turkish stemmer, and it seems like good insurance against any other safety or performance issues that may exist in the Snowball stemmers. Such a long string is surely not a word in any human language, so it's doubtful that the stemmer would have done anything desirable with it anyway.

- Fix use-after-free hazard in string comparisons (Tom Lane)

Improper memory management in the string comparison functions could result in scribbling on no-longer-allocated buffers, potentially breaking things for whatever is using that memory now. This would only happen with fairly long strings (more than 1kB), and only if an ICU collation is in use.

- Prevent postmaster crash when shared-memory state is corrupted (Tom Lane)

The postmaster process is supposed to survive and initiate a database restart if shared memory becomes corrupted, but one bit of code was being insufficiently cautious about that.

- Add some more defenses against recursion till stack overrun (Richard Guo, Tom Lane)
- Avoid long-term memory leakage in the autovacuum launcher process (Reid Thompson)

The lack of field reports suggests that this problem is only latent in pre-v15 branches; but it's not very clear why, so back-patch the fix anyway.

- Improve PL/pgSQL's ability to handle parameters declared as `RECORD` (Tom Lane)

Build a separate function cache entry for each concrete type passed to the `RECORD` parameter during a session, much as we do for polymorphic parameters. This allows some usages to work that previously failed with errors such as “type of parameter does not match that when preparing the plan”.

- Add missing guards for `NULL` connection pointer in `libpq` (Daniele Varrazzo, Tom Lane)

There's a convention that `libpq` functions should check for a `NULL PGconn` argument, and fail gracefully instead of crashing. `PQflush()` and `PQisnonblocking()` didn't get that memo, so fix them.

- In `ecpg`, fix omission of variable storage classes when multiple `varchar` or `bytea` variables are declared in the same declaration (Andrey Sokolov)

For example, `ecpg` translated `static varchar str1[10], str2[20], str3[30];` in such a way that only `str1` was marked `static`.

- Allow cross-platform tablespace relocation in `pg_basebackup` (Robert Haas)

Allow the remote path in `--tablespace-mapping` to be either a Unix-style or Windows-style absolute path, since the source server could be on a different OS than the local system.

- In `pg_stat_statements`, fix access to already-freed memory (zhaoqigui)

This occurred if `pg_stat_statements` tracked a `ROLLBACK` command issued via extended query protocol. In debug builds it consistently led to an assertion failure. In production builds there would often be no visible ill effect; but if the freed memory had already been reused, the likely result would be to store garbage for the query string.

- In `postgres_fdw`, ensure that target lists constructed for `EvalPlanQual` plans will have all required columns (Richard Guo, Etsuro Fujita)

This avoids “variable not found in subplan target list” errors in rare cases.

- Reject unwanted output from the platform's `uuid_create()` function (Nazir Bilal Yavuz)

The `uuid-oss` module expects `libc`'s `uuid_create()` to produce a version-1 UUID, but recent NetBSD releases produce a version-4 (random) UUID instead. Check for that, and complain if so. Drop the documentation's claim that the NetBSD implementation is usable for `uuid-oss`. (If a version-4 UUID is okay for your purposes, you don't need `uuid-oss` at all; just use `gen_random_uuid()`.)

- Include new Perl test modules in standard installations (Álvaro Herrera)

Add `PostgreSQL/Test/Cluster.pm` and `PostgreSQL/Test/Utils.pm` to the standard installation file set in pre-version-15 branches. This is for the benefit of extensions that want to use newly-written test code in older branches.

- On NetBSD, force dynamic symbol resolution at postmaster start (Andres Freund, Tom Lane)

This avoids a risk of deadlock in the dynamic linker on NetBSD 10.

- Fix incompatibilities with LLVM 15 (Thomas Munro, Andres Freund)

- Allow use of `__sync_lock_test_and_set()` for spinlocks on any machine (Tom Lane)

This eases porting to new machine architectures, at least if you're using a compiler that supports this GCC builtin function.

- Rename symbol `REF` to `REF_P` to avoid compile failure on recent macOS (Tom Lane)
- Silence assorted compiler warnings from clang 15 and later (Tom Lane)
- Update time zone data files to tzdata release 2022f for DST law changes in Chile, Fiji, Iran, Jordan, Mexico, Palestine, and Syria, plus historical corrections for Chile, Crimea, Iran, and Mexico.

Also, the Europe/Kiev zone has been renamed to Europe/Kyiv. Also, the following zones have been merged into nearby, more-populous zones whose clocks have agreed with them since 1970: Antarctica/Vostok, Asia/Brunei, Asia/Kuala\_Lumpur, Atlantic/Reykjavik, Europe/Amsterdam, Europe/Copenhagen, Europe/Luxembourg, Europe/Monaco, Europe/Oslo, Europe/Stockholm, Indian/Christmas, Indian/Cocos, Indian/Kerguelen, Indian/Mahe, Indian/Reunion, Pacific/Chuuk, Pacific/Funafuti, Pacific/Majuro, Pacific/Pohnpei, Pacific/Wake and Pacific/Wallis. (This indirectly affects zones that were already links to one of these: Arctic/Longyearbyen, Atlantic/Jan\_Mayen, Iceland, Pacific/Ponape, Pacific/Truk, and Pacific/Yap.) America/Nipigon, America/Rainy\_River, America/Thunder\_Bay, Europe/Uzhgorod, and Europe/Zaporozhye were also merged into nearby zones after discovering that their claimed post-1970 differences from those zones seem to have been errors. In all these cases, the previous zone name remains as an alias; but the actual data is that of the zone that was merged into.

These zone mergers result in loss of pre-1970 timezone history for the merged zones, which may be troublesome for applications expecting consistency of `timestampz` display. As an example, the stored value `1944-06-01 12:00 UTC` would previously display as `1944-06-01 13:00:00+01` if the Europe/Stockholm zone is selected, but now it will read out as `1944-06-01 14:00:00+02`.

It is possible to build the time zone data files with options that will restore the older zone data, but that choice also inserts a lot of other old (and typically poorly-attested) zone data, resulting in more total changes from the previous release than accepting these upstream changes does. PostgreSQL has chosen to ship the tzdb data as-recommended, and so far as we are aware most major operating system distributions are doing likewise. However, if these changes cause significant problems for your application, a possible solution is to install a local build of the time zone data files using tzdb's backwards-compatibility options (see their `PACKRATDATA` and `PACKRATLIST` options).

## E.29. Release 11.17

**Release date:** 2022-08-11

This release contains a variety of fixes from 11.16. For information about new features in major release 11, see [Section E.46](#).

### E.29.1. Migration to Version 11.17

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.14, see [Section E.32](#).

### E.29.2. Changes

- Do not let extension scripts replace objects not already belonging to the extension (Tom Lane)

This change prevents extension scripts from doing `CREATE OR REPLACE` if there is an existing object that does not belong to the extension. It also prevents `CREATE IF NOT EXISTS` in the same situation. This prevents a form of trojan-horse attack in which a hostile database user could become the owner of an extension object and then modify it to compromise future uses of the object by other users. As a side benefit, it also reduces the risk of accidentally replacing objects one did not mean to.

The PostgreSQL Project thanks Sven Klemm for reporting this problem. (CVE-2022-2625)

- Fix replay of `CREATE DATABASE` WAL records on standby servers (Kyotaro Horiguchi, Asim R Praveen, Paul Guo)

Standby servers may encounter missing tablespace directories when replaying database-creation WAL records. Prior to this patch, a standby would fail to recover in such a case; however, such directories could be legitimately missing. Create the tablespace (as a plain directory), then check that it has been dropped again once replay reaches a consistent state.

- Support “in place” tablespaces (Thomas Munro, Michael Paquier, Álvaro Herrera)

Normally a Postgres tablespace is a symbolic link to a directory on some other filesystem. This change allows it to just be a plain directory. While this has no use for separating tables onto different filesystems, it is a convenient setup for testing. Moreover, it is necessary to support the `CREATE DATABASE` replay fix, which transiently creates a missing tablespace as an “in place” tablespace.

- Fix permissions checks in `CREATE INDEX` (Nathan Bossart, Noah Misch)

The fix for CVE-2022-1552 caused `CREATE INDEX` to apply the table owner's permissions while performing lookups of operator classes and other objects, where formerly the calling user's permissions were used. This broke dump/restore scenarios, because `pg_dump` issues `CREATE INDEX` before re-granting permissions.

- In extended query protocol, force an immediate commit after `CREATE DATABASE` and other commands that can't run in a transaction block (Tom Lane)

If the client does not send a Sync message immediately after such a command, but instead sends another command, any failure in that command would lead to rolling back the preceding command, typically leaving inconsistent state on-disk (such as a missing or extra database directory). The mechanisms intended to prevent that situation turn out to work for multiple commands in a simple-Query message, but not for a series of extended-protocol messages. To prevent inconsistency without breaking use-cases that work today, force an implicit commit after such commands.

- Fix race condition when checking transaction visibility (Simon Riggs)

`TransactionIdIsInProgress` could report `false` before the subject transaction is considered visible, leading to various misbehaviors. The race condition window is normally very narrow, but use of synchronous replication makes it much wider, because the wait for a synchronous replica happens in that window.

- Fix queries in which a “whole-row variable” references the result of a function that returns a domain over composite type (Tom Lane)
- Fix “variable not found in subplan target list” planner error when pulling up a sub-`SELECT` that's referenced in a `GROUPING` function (Richard Guo)
- Fix `ALTER TABLE ... ENABLE/DISABLE TRIGGER` to handle recursion correctly for triggers on partitioned tables (Álvaro Herrera, Amit Langote)

In certain cases, a “trigger does not exist” failure would occur because the command would try to adjust the trigger on a child partition that doesn't have it.

- Prevent `pg_stat_get_subscription()` from possibly returning an extra row containing garbage values (Kuntal Ghosh)
- Ensure that `pg_stop_backup()` cleans up session state properly (Fujii Masao)

This omission could lead to assertion failures or crashes later in the session.

- Fix join alias matching in `FOR [KEY] UPDATE/SHARE` clauses (Dean Rasheed)

In corner cases, a misleading error could be reported.

- Avoid crashing if too many column aliases are attached to an `XMLTABLE` or `JSON_TABLE` construct (Álvaro Herrera)
- Reject `ROW()` expressions and functions in `FROM` that have too many columns (Tom Lane)

Cases with more than about 1600 columns are unsupported, and have always failed at execution. However, it emerges that some earlier code could be driven to assertion failures or crashes by queries with more than 32K columns. Add a parse-time check to prevent that.

- When decompiling a view or rule, show a `SELECT` output column's `AS "?column?"` alias clause if it could be referenced elsewhere (Tom Lane)

Previously, this auto-generated alias was always hidden; but there are corner cases where doing so results in a non-restorable view or rule definition.

- Fix dumping of a view using a function in `FROM` that returns a composite type, when column(s) of the composite type have been dropped since the view was made (Tom Lane)

This oversight could lead to dump/reload or `pg_upgrade` failures, as the dumped view would have too many column aliases for the function.

- Report implicitly-created operator families to event triggers (Masahiko Sawada)

If `CREATE OPERATOR CLASS` results in the implicit creation of an operator family, that object was not reported to event triggers that should capture such events.

- Fix control file updates made when a restartpoint is running during promotion of a standby server (Kyotaro Horiguchi)

Previously, when the restartpoint completed it could incorrectly update the last-checkpoint fields of the control file, potentially leading to PANIC and failure to restart if the server crashes before the next normal checkpoint completes.

- Prevent triggering of standby's `wal_receiver_timeout` during logical replication of large transactions (Wang Wei, Amit Kapila)

If a large transaction on the primary server sends no data to the standby (perhaps because no table it changes is published), it was possible for the standby to timeout. Fix that by ensuring we send keepalive messages periodically in such situations.

- Disallow nested backup operations in logical replication walsenders (Fujii Masao)
- Fix memory leak in logical replication subscribers (Hou Zhijie)
- Prevent open-file leak when reading an invalid timezone abbreviation file (Kyotaro Horiguchi)

Such cases could result in harmless warning messages.

- Allow custom server parameters to have short descriptions that are NULL (Steve Chavez)

Previously, although extensions could choose to create such settings, some code paths would crash while processing them.

- Fix WAL consistency checking logic to correctly handle `BRIN_EVACUATE_PAGE` flags (Haiyang Wang)
- Fix erroneous assertion checks in shared hashtable management (Thomas Munro)
- Arrange to clean up after commit-time errors within `SPI_commit()`, rather than expecting callers to do that (Peter Eisentraut, Tom Lane)

Proper cleanup is complicated and requires use of low-level facilities, so it's not surprising that no known caller got it right. This led to misbehaviors when a PL procedure issued `COMMIT` but a failure occurred (such as a deferred constraint check). To improve matters, redefine `SPI_commit()` as starting a new transaction, so that it becomes equivalent to `SPI_commit_and_chain()` except that you get default transaction characteristics instead of preserving the prior transaction's characteris-

tics. To make this somewhat transparent API-wise, redefine `SPI_start_transaction()` as a no-op. All known callers of `SPI_commit()` immediately call `SPI_start_transaction()`, so they will not notice any change. Similar remarks apply to `SPI_rollback()`.

Also fix PL/Python, which omitted any handling of such errors at all, resulting in jumping out of the Python interpreter. This is reported to crash Python 3.11. Older Python releases leak some memory but seem okay with it otherwise.

- Remove misguided SSL key file ownership check in libpq (Tom Lane)

In the previous minor releases, we copied the server's permission checking rules for SSL private key files into libpq. But we should not have also copied the server's file-ownership check. While that works in normal use-cases, it can result in an unexpected failure for clients running as root, and perhaps in other cases.

- Ensure ecpg reports server connection loss sanely (Tom Lane)

Misprocessing of a libpq-generated error result, such as a report of lost connection, would lead to printing "(null)" instead of a useful error message; or in older releases it would lead to a crash.

- Avoid core dump in ecpglib with unexpected orders of operations (Tom Lane)

Certain operations such as `EXEC SQL PREPARE` would crash (rather than reporting an error as expected) if called before establishing any database connection.

- In ecpglib, avoid redundant `newlocale()` calls (Noah Misch)

Allocate a C locale object once per process when first connecting, rather than creating and freeing locale objects once per query. This mitigates a libc memory leak on AIX, and may offer some performance benefit everywhere.

- In psql's `\watch` command, echo a newline after cancellation with control-C (Pavel Stehule)

This prevents libedit (and possibly also libreadline) from becoming confused about which column the cursor is in.

- Fix `contrib/pg_stat_statements` to avoid problems with very large query-text files on 32-bit platforms (Tom Lane)
- Ensure that `contrib/postgres_fdw` sends constants of `regconfig` and other `reg*` types with proper schema qualification (Tom Lane)
- Block signals while allocating dynamic shared memory on Linux (Thomas Munro)

This avoids problems when a signal interrupts `posix_fallocate()`.

- Detect unexpected `EEXIST` error from `shm_open()` (Thomas Munro)

This avoids a possible crash on Solaris.

- Adjust PL/Perl test case so it will work under Perl 5.36 (Dagfinn Ilmari Mannsåker)
- Avoid incorrectly using an out-of-date `libldap_r` library when multiple OpenLDAP installations are present while building PostgreSQL (Tom Lane)

## E.30. Release 11.16

**Release date:** 2022-05-12

This release contains a variety of fixes from 11.15. For information about new features in major release 11, see [Section E.46](#).

### E.30.1. Migration to Version 11.16

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.14, see [Section E.32](#).

### E.30.2. Changes

- Confine additional operations within “security restricted operation” sandboxes (Sergey Shinderuk, Noah Misch)

Autovacuum, `CLUSTER`, `CREATE INDEX`, `REINDEX`, `REFRESH MATERIALIZED VIEW`, and `pg_amcheck` activated the “security restricted operation” protection mechanism too late, or even not at all in some code paths. A user having permission to create non-temporary objects within a database could define an object that would execute arbitrary SQL code with superuser permissions the next time that autovacuum processed the object, or that some superuser ran one of the affected commands against it.

The PostgreSQL Project thanks Alexander Lakhin for reporting this problem. (CVE-2022-1552)

- Stop using query-provided column aliases for the columns of whole-row variables that refer to plain tables (Tom Lane)

The column names in tuples produced by a whole-row variable (such as `tbl.*` in contexts other than the top level of a `SELECT` list) are now always those of the associated named composite type, if there is one. We'd previously attempted to make them track any column aliases that had been applied to the `FROM` entry the variable refers to. But that's semantically dubious, because really then the output of the variable is not at all of the composite type it claims to be. Previous attempts to deal with that inconsistency had bad results up to and including storing unreadable data on disk, so just give up on the whole idea.

In cases where it's important to be able to relabel such columns, a workaround is to introduce an extra level of sub-`SELECT`, so that the whole-row variable is referring to the sub-`SELECT`'s output and not to a plain table. Then the variable is of type `record` to begin with and there's no issue.

- Fix incorrect output for types `timestamptz` and `timetz` in `table_to_xmlschema()` and allied functions (Renan Soares Lopes)

The `xmlschema` output for these types included a malformed regular expression.

- Avoid core dump in parser for a `VALUES` clause with zero columns (Tom Lane)
- Fix planner errors for `GROUPING()` constructs that reference outer query levels (Richard Guo, Tom Lane)
- Fix plan generation for index-only scans on indexes with both returnable and non-returnable columns (Tom Lane)

The previous coding could try to read non-returnable columns in addition to the returnable ones. This was fairly harmless because it didn't actually do anything with the bogus values, but it fell foul of a recently-added error check that rejected such a plan.

- Fix query-lifespan memory leak in an `IndexScan` node that is performing reordering (Aliaksandr Kalenik)
- Fix `ALTER FUNCTION` to support changing a function's parallelism property and its `SET`-variable list in the same command (Tom Lane)

The parallelism property change was lost if the same command also updated the function's `SET` clause.

- Fix mis-sorting of table rows when `CLUSTERING` using an index whose leading key is an expression (Peter Geoghegan, Thomas Munro)

The table would be rebuilt with the correct data, but in an order having little to do with the index order.

- Fix risk of deadlock failures while dropping a partitioned index (Jimmy Yih, Gaurab Dey, Tom Lane)

Ensure that the required table and index locks are taken in the standard order (parents before children, tables before indexes). The previous coding for `DROP INDEX` did it differently, and so could deadlock against concurrent queries taking these locks in the standard order.

- Fix race condition between `DROP TABLESPACE` and checkpointing (Nathan Bossart)

The checkpoint forced by `DROP TABLESPACE` could sometimes fail to remove all dead files from the tablespace's directory, leading to a bogus “tablespace is not empty” error.

- Fix possible trouble in crash recovery after a `TRUNCATE` command that overlaps a checkpoint (Kyotaro Horiguchi, Heikki Linnakangas, Robert Haas)

`TRUNCATE` must ensure that the table's disk file is truncated before the checkpoint is allowed to complete. Otherwise, replay starting from that checkpoint might find unexpected data in the supposedly-removed pages, possibly causing replay failure.

- Fix unsafe toast-data accesses during temporary object cleanup (Andres Freund)

Temporary-object deletion during server process exit could fail with “FATAL: cannot fetch toast data without an active snapshot”. This was usually harmless since the next use of that temporary schema would clean up successfully.

- Fix “PANIC: xlog flush request is not satisfied” failure during standby promotion when there is a missing WAL continuation record (Sami Imseih)
- Fix possibility of self-deadlock in hot standby conflict handling (Andres Freund)

With unlucky timing, the WAL-applying process could get stuck while waiting for some other process to release a buffer lock.

- Ensure that logical replication apply workers can be restarted even when we're up against the `max_sync_workers_per_subscription` limit (Amit Kapila)

Faulty coding of the limit check caused a restarted worker to exit immediately, leaving fewer workers than there should be.

- Include unchanged replica identity key columns in the WAL log for an update, if they are stored out-of-line (Dilip Kumar, Amit Kapila)

Otherwise subscribers cannot see the values and will fail to replicate the update.

- Improve logical replication subscriber's error message for an unsupported relation kind (Tom Lane)

v13 and later servers support publishing partitioned tables. Older server versions cannot handle subscribing to such a table, and they gave a very misleading error message: “table XYZ not found on publisher”. Arrange to deliver a more on-point message.

- Disallow execution of SPI functions during PL/Perl function compilation (Tom Lane)

Perl can be convinced to execute user-defined code during compilation of a PL/Perl function. However, it's not okay for such code to try to invoke SQL operations via SPI. That results in a crash, and if it didn't crash it would be a security hazard, because we really don't want code execution during function validation. Put in a check to give a friendlier error message instead.

- Make libpq accept root-owned SSL private key files (David Steele)

This change synchronizes libpq's rules for safe ownership and permissions of SSL key files with the rules the server has used since release 9.6. Namely, in addition to the current rules, allow the case where the key file is owned by root and has permissions `rw-r-----` or less. This is helpful for system-wide management of key files.

- Make `pg_ctl` recheck postmaster aliveness while waiting for stop/restart/promote actions (Tom Lane)

`pg_ctl` would verify that the postmaster is alive as a side-effect of sending the stop or promote signal, but then it just naively waited to see the on-disk state change. If the postmaster died uncleanly without having removed its PID file or updated the control file, `pg_ctl` would wait until timeout. Instead make it recheck every so often that the postmaster process is still there.

- Fix error handling in `pg_waldump` (Kyotaro Horiguchi, Andres Freund)

While trying to read a WAL file to determine the WAL segment size, `pg_waldump` would report an incorrect error for the case of a too-short file. In addition, the file name reported in this and related error messages could be garbage.

- Ensure that `contrib/pageinspect` functions cope with all-zero pages (Michael Paquier)

This is a legitimate edge case, but the module was mostly unprepared for it. Arrange to return nulls, or no rows, as appropriate; that seems more useful than raising an error.

- In `contrib/pageinspect`, add defenses against incorrect page “special space” contents, tighten checks for correct page size, and add some missing checks that an index is of the expected type (Michael Paquier, Justin Pryzby, Julien Rouhaud)

These changes make it less likely that the module will crash on bad data.

- In `contrib/postgres_fdw`, verify that `ORDER BY` clauses are safe to ship before requesting a remotely-ordered query, and include a `USING` clause if necessary (Ronan Dunklau)

This fix prevents situations where the remote server might sort in a different order than we intend. While sometimes that would be only cosmetic, it could produce thoroughly wrong results if the remote data is used as input for a locally-performed merge join.

- Update JIT code to work with LLVM 14 (Thomas Munro)
- Clean up assorted failures under clang's `-fsanitize=undefined` checks (Tom Lane, Andres Freund, Zhihong Yu)

Most of these changes are just for pro-forma compliance with the letter of the C and POSIX standards, and are unlikely to have any effect on production builds.

- Fix PL/Perl so it builds on C compilers that don't support statements nested within expressions (Tom Lane)

- Fix possible build failure of `pg_dumpall` on Windows, when not using MSVC to build (Andres Freund)
- In Windows builds, use `gendef` instead of `pexports` to build DEF files (Andrew Dunstan)

This adapts the build process to work on recent MSys tool chains.

- Prevent extra expansion of shell wildcard patterns in programs built under MinGW (Andrew Dunstan)

For some reason the C library provided by MinGW will expand shell wildcard characters in a program's command-line arguments by default. This is confusing, not least because it doesn't happen under MSVC, so turn it off.

- Update time zone data files to tzdata release 2022a for DST law changes in Palestine, plus historical corrections for Chile and Ukraine.

## E.31. Release 11.15

**Release date:** 2022-02-10

This release contains a variety of fixes from 11.14. For information about new features in major release 11, see [Section E.46](#).

### E.31.1. Migration to Version 11.15

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.14, see [Section E.32](#).

### E.31.2. Changes

- Fix index-only scan plans for cases where not all index columns can be returned (Tom Lane)

If an index has both returnable and non-returnable columns, and one of the non-returnable columns is an expression using a table column that appears in a returnable index column, then a query using that expression could result in an index-only scan plan that attempts to read the non-returnable column, instead of recomputing the expression from the returnable column as intended. The non-returnable column would read as NULL, resulting in wrong query results.

- Ensure that casting to an unspecified typmod generates a RelabelType node rather than a length-coercion function call (Tom Lane)

While the coercion function should do the right thing (nothing), this translation is undesirably inefficient.

- Fix WAL replay failure when database consistency is reached exactly at a WAL page boundary (Álvaro Herrera)
- Fix startup of a physical replica to tolerate transaction ID wraparound (Abhijit Menon-Sen, Tomas Vondra)

If a replica server is started while the set of active transactions on the primary crosses a wrap-around boundary (so that there are some newer transactions with smaller XIDs than older ones), the replica would fail with “out-of-order XID insertion in KnownAssignedXids”. The replica would retry, but could never get past that error.

- Remove lexical limitations for SQL commands issued on a logical replication connection (Tom Lane)

The walsender process would fail for a SQL command containing an unquoted semicolon, or with dollar-quoted literals containing odd numbers of single or double quote marks, or when the SQL command starts with a comment. Moreover, faulty error recovery could lead to unexpected errors in later commands too.

- Fix possible loss of the commit timestamp for the last subtransaction of a transaction (Alex Kingsborough, Kyotaro Horiguchi)
- Be sure to `fsync` the `pg_logical/mappings` subdirectory during checkpoints (Nathan Bossart)

On some filesystems this oversight could lead to losing logical rewrite status files after a system crash.

- Build extended statistics for partitioned tables (Justin Pryzby)

A previous bug fix disabled building of extended statistics for old-style inheritance trees, but it also prevented building them for partitioned tables, which was an unnecessary restriction. This change allows `ANALYZE` to compute values for statistics objects for partitioned tables. (But note that `autovacuum` does not process partitioned tables as such, so you must periodically issue manual `ANALYZE` on the partitioned table if you want to maintain such statistics.)

- Ignore extended statistics for inheritance trees (Justin Pryzby)

Currently, extended statistics values are only computed locally for each table, not for entire inheritance trees. However the values were mistakenly consulted when planning queries across inheritance trees, possibly resulting in worse-than-default estimates.

- Disallow altering data type of a partitioned table's columns when the partitioned table's row type is used as a composite type elsewhere (Tom Lane)

This restriction has long existed for regular tables, but through an oversight it was not checked for partitioned tables.

- Disallow `ALTER TABLE ... DROP NOT NULL` for a column that is part of a replica identity index (Haiying Tang, Hou Zhijie)

The same prohibition already existed for primary key indexes.

- Correctly update cached table state during `ALTER TABLE ADD PRIMARY KEY USING INDEX` (Hou Zhijie)

Concurrent sessions failed to update their opinion of whether the table has a primary key, possibly causing incorrect logical replication behavior.

- Correctly update cached table state when switching `REPLICA IDENTITY` index (Tang Haiying, Hou Zhijie)

Concurrent sessions failed to update their opinion of which index is the replica identity one, possibly causing incorrect logical replication behavior.

- Avoid leaking memory during `REASSIGN OWNED BY` operations that reassign ownership of many objects (Justin Pryzby)
- Fix display of whole-row variables appearing in `INSERT ... VALUES` rules (Tom Lane)

A whole-row variable would be printed as `"var.*"`, but that allows it to be expanded to individual columns when the rule is reloaded, resulting in different semantics. Attach an explicit cast to prevent that, as we do elsewhere.

- Fix or remove some incorrect assertions (Simon Riggs, Michael Paquier, Alexander Lakhin)

These errors should affect only debug builds, not production.

- Fix race condition that could lead to failure to localize error messages that are reported early in multi-threaded use of `libpq` or `ecpglib` (Tom Lane)
- Avoid calling `strerror` from `libpq`'s `PQcancel` function (Tom Lane)

`PQcancel` is supposed to be safe to call from a signal handler, but `strerror` is not safe. The faulty usage only occurred in the unlikely event of failure to send the cancel message to the server, perhaps explaining the lack of reports.

- Make `psql`'s `\password` command default to setting the password for `CURRENT_USER`, not the connection's original user name (Tom Lane)

This agrees with the documented behavior, and avoids probable permissions failure if `SET ROLE` or `SET SESSION AUTHORIZATION` has been done since the session began. To prevent confusion, the role name to be acted on is now included in the password prompt.

- In `psql` and some other client programs, avoid trying to invoke `gettext()` from a control-C signal handler (Tom Lane)

While no reported failures have been traced to this mistake, it seems highly unlikely to be a safe thing to do.

- Allow canceling the initial password prompt in `pg_receivewal` and `pg_recvlogical` (Tom Lane, Nathan Bossart)

Previously it was impossible to terminate these programs via control-C while they were prompting for a password.

- Fix `pg_dump`'s dump ordering for user-defined casts (Tom Lane)

In rare cases, the output script might refer to a user-defined cast before it had been created.

- Fix possible mis-reporting of errors in `pg_dump` and `pg_basebackup` (Tom Lane)

The previous code failed to check for errors from some kernel calls, and could report the wrong `errno` values in other cases.

- Fix results of index-only scans on `contrib/btree_gist` indexes on `char(N)` columns (Tom Lane)

Index-only scans returned column values with trailing spaces removed, which is not the expected behavior. That happened because that's how the data was stored in the index. This fix changes the code to store `char(N)` values with the expected amount of space padding. The behavior of such an index will not change immediately unless you `REINDEX` it; otherwise space-stripped values will be gradually replaced over time during updates. Queries that do not use index-only scan plans will be unaffected in any case.

- Change `configure` to use Python's `sysconfig` module, rather than the deprecated `distutils` module, to determine how to build PL/Python (Peter Eisentraut, Tom Lane, Andres Freund)

With Python 3.10, this avoids `configure`-time warnings about `distutils` being deprecated and scheduled for removal in Python 3.12. Presumably, once 3.12 is out, `configure --with-python` would fail altogether. This future-proofing does come at a cost: `sysconfig` did not exist before Python 2.7, nor before 3.2 in the Python 3 branch, so it is no longer possible to build PL/Python against long-dead Python versions.

- Fix PL/Perl compile failure on Windows with Perl 5.28 and later (Victor Wagner)
- Fix PL/Python compile failure with Python 3.11 and later (Peter Eisentraut)
- Add support for building with Visual Studio 2022 (Hans Buschmann)
- Allow the `.bat` wrapper scripts in our MSVC build system to be called without first changing into their directory (Anton Voloshin, Andrew Dunstan)

## E.32. Release 11.14

**Release date:** 2021-11-11

This release contains a variety of fixes from 11.13. For information about new features in major release 11, see [Section E.46](#).

### E.32.1. Migration to Version 11.14

A dump/restore is not required for those running 11.X.

However, note that installations using physical replication should update standby servers before the primary server, as explained in the third changelog entry below.

Also, several bugs have been found that may have resulted in corrupted indexes, as explained in the next several changelog entries. If any of those cases apply to you, it's recommended to `reindex` possibly-affected indexes after updating.

Also, if you are upgrading from a version earlier than 11.11, see [Section E.35](#).

### E.32.2. Changes

- Make the server reject extraneous data after an SSL or GSS encryption handshake (Tom Lane)

A man-in-the-middle with the ability to inject data into the TCP connection could stuff some cleartext data into the start of a supposedly encryption-protected database session. This could be abused to send faked SQL commands to the server, although that would only work if the server did not demand any authentication data. (However, a server relying on SSL certificate authentication might well not do so.)

The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2021-23214)

- Make libpq reject extraneous data after an SSL or GSS encryption handshake (Tom Lane)

A man-in-the-middle with the ability to inject data into the TCP connection could stuff some cleartext data into the start of a supposedly encryption-protected database session. This could probably be abused to inject faked responses to the client's first few queries, although other details of libpq's behavior make that harder than it sounds. A different line of attack is to exfiltrate the client's password, or other sensitive data that might be sent early in the session. That has been shown to be possible with a server vulnerable to CVE-2021-23214.

The PostgreSQL Project thanks Jacob Champion for reporting this problem. (CVE-2021-23222)

- Fix physical replication for cases where the primary crashes after shipping a WAL segment that ends with a partial WAL record (Álvaro Herrera)

If the primary did not survive long enough to finish writing the rest of the incomplete WAL record, then the previous crash-recovery logic had it back up and overwrite WAL starting from the beginning of the incomplete WAL record. This is problematic since standby servers may already have copies of that WAL segment. They will then see an inconsistent next segment, and will not be able to recover without manual intervention. To fix, do not back up over a WAL segment boundary when restarting after a crash. Instead write a new type of WAL record at the start of the next WAL segment, informing readers that the incomplete WAL record will never be finished and must be disregarded.

When applying this update, it's best to update standby servers before the primary, so that they will be ready to handle this new WAL record type if the primary happens to crash.

- Fix `CREATE INDEX CONCURRENTLY` to wait for the latest prepared transactions (Andrey Borodin)

Rows inserted by just-prepared transactions might be omitted from the new index, causing queries relying on the index to miss such rows. The previous fix for this type of problem failed to account for `PREPARE TRANSACTION` commands that were still in progress when `CREATE INDEX CONCURRENTLY` checked for them. As before, in installations that have enabled prepared transactions (`max_prepared_transactions > 0`), it's recommended to reindex any concurrently-built indexes in case this problem occurred when they were built.

- Avoid race condition that can cause backends to fail to add entries for new rows to an index being built concurrently (Noah Misch, Andrey Borodin)

While it's apparently rare in the field, this case could potentially affect any index built or reindexed with the `CONCURRENTLY` option. It is recommended to reindex any such indexes to make sure they are correct.

- Fix `float4` and `float8` hash functions to produce uniform results for NaNs (Tom Lane)

Since PostgreSQL's floating-point types deem all NaNs to be equal, it's important for the hash functions to produce the same hash code for all bit-patterns that are NaNs according to the IEEE 754 standard. This failed to happen before, meaning that hash indexes and hash-based query plans might produce incorrect results for non-canonical NaN values. (`'-NaN'::float8` is one way to produce such a value on most machines.) It is advisable to reindex hash indexes on floating-point columns, if there is any possibility that they might contain such values.

- Prevent data loss during crash recovery of `CREATE TABLESPACE`, when `wal_level = minimal` (Noah Misch)

If the server crashed between `CREATE TABLESPACE` and the next checkpoint, replay would fully remove the contents of the new tablespace's directory, relying on subsequent WAL replay to restore everything within that directory. This interacts badly with optimizations that skip writing WAL (one example is `COPY` into a just-created table). Such optimizations are applied only when `wal_level` is `minimal`, which is not the default in v10 and later.

- Ensure that the relation cache is invalidated for a table being attached to or detached from a partitioned table (Amit Langote, Álvaro Herrera)

This oversight could allow misbehavior of subsequent inserts/updates addressed directly to the partition, but only in currently-existing sessions.

- Ensure that the relation cache is invalidated when creating or dropping a `FOR ALL TABLES` publication (Hou Zhijie, Vignesh C)

This oversight could lead to improper replication behavior until all currently-existing sessions have exited.

- Don't discard a cast to the same type with unspecified type modifier (Tom Lane)

For example, if column `f1` is of type `numeric(18,3)`, the parser used to simply discard a cast like `f1::numeric`, on the grounds that it would have no run-time effect. That's true, but the exposed type of the expression should still be considered to be plain `numeric`, not `numeric(18,3)`. This is important for correctly resolving the type of larger constructs, such as recursive `UNIONS`.

- Fix updates of element fields in arrays of domain over composite (Tom Lane)

A command such as `UPDATE tab SET fld[1].subfld = val` failed if the array's elements were domains rather than plain composites.

- Disallow creating an ICU collation if the current database's encoding won't support it (Tom Lane)

Previously this was allowed, but then the collation could not be referenced because of the way collation lookup works; you could not use the collation, nor even drop it.

- Fix corner-case loss of precision in `numeric power()` (Dean Rasheed)

The result could be inaccurate when the first argument is very close to 1.

- Avoid regular expression errors with capturing parentheses inside `{0}` (Tom Lane)

Regular expressions like `(.) {0} ... \1` drew “invalid backreference number”. Other regexp engines such as Perl don't complain, though, and for that matter ours doesn't either in some closely related cases. Worse, it could throw an assertion failure instead. Fix it so that no error is thrown and instead the back-reference is silently deemed to never match.

- Prevent regular expression back-references from sometimes matching when they shouldn't (Tom Lane)

The regexp engine was careless about clearing match data for capturing parentheses after rejecting a partial match. This could allow a later back-reference to match in places where it should fail for lack of a defined referent.

- Fix regular expression performance bug with back-references inside iteration nodes (Tom Lane)

Incorrect back-tracking logic could result in exponential time spent looking for a match. Fortunately the problem is masked in most cases by other optimizations.

- Fix incorrect results from `AT TIME ZONE` applied to a time with time zone value (Tom Lane)

The results were incorrect if the target time zone was specified by a dynamic timezone abbreviation (that is, one that is defined as equivalent to a full time zone name, rather than a fixed UTC offset).

- Avoid using MCV-only statistics to estimate the range of a column (Tom Lane)

There are corner cases in which `ANALYZE` will build a most-common-values (MCV) list but not a histogram, even though the MCV list does not account for all the observed values. In such cases, keep the planner from using the MCV list alone to estimate the range of column values.

- Fix restoration of a Portal's snapshot inside a subtransaction (Bertrand Drouvot)

If a procedure commits or rolls back a transaction, and then its next significant action is inside a new subtransaction, snapshot management went wrong, leading to a dangling pointer and probable

crash. A typical example in PL/pgSQL is a `COMMIT` immediately followed by a `BEGIN ... EXCEPTION` block that performs a query.

- Clean up correctly if a transaction fails after exporting its snapshot (Dilip Kumar)

This oversight would only cause a problem if the same session attempted to export a snapshot again. The most likely scenario for that is creation of a replication slot (followed by rollback) and then creation of another replication slot.

- Prevent wraparound of overflowed-subtransaction tracking on standby servers (Kyotaro Horiguchi, Alexander Korotkov)

This oversight could cause significant performance degradation (manifesting as excessive SubtransSLRU traffic) on standby servers.

- Ensure that prepared transactions are properly accounted for during promotion of a standby server (Michael Paquier, Andres Freund)

There was a narrow window where a prepared transaction could be omitted from a snapshot taken by a concurrently-running session. If that session then used the snapshot to perform data updates, erroneous results or data corruption could occur.

- Refuse to rewind a cursor marked `NO SCROLL` if it has been held over from a previous transaction due to the `WITH HOLD` option (Tom Lane)

We have long forbidden fetching backwards from a `NO SCROLL` cursor, but for historical reasons the prohibition didn't extend to cases in which we rewind the query altogether and then re-fetch forwards. That exception leads to inconsistencies, particularly for held-over cursors which may not have stored all the data necessary to rewind. Disallow rewinding for non-scrollable held-over cursors to block the worst inconsistencies. (v15 will remove the exception altogether.)

- Fix possible failure while saving a `WITH HOLD` cursor at transaction end, if it had already been read to completion (Tom Lane)
- Fix detection of a relation that has grown to the maximum allowed length (Tom Lane)

An attempt to extend a table or index past the limit of  $2^{32}-1$  blocks was rejected, but not soon enough to prevent inconsistent internal state from being created.

- Correctly track the presence of data-modifying CTEs when expanding a `DO INSTEAD` rule (Greg Nancarrow, Tom Lane)

The previous failure to do this could lead to problems such as unsafely choosing a parallel plan.

- Fix incorrect reporting of permissions failures on extended statistics objects (Tomas Vondra)

The code typically produced “cache lookup error” rather than the intended message.

- Fix incorrect snapshot handling in parallel workers (Greg Nancarrow)

This oversight could lead to misbehavior in parallel queries if the transaction isolation level is less than `REPEATABLE READ`.

- Fix logical decoding to correctly ignore toast-table changes for transient tables (Bertrand Drouvot)

Logical decoding normally ignores changes in transient tables such as those created during an `ALTER TABLE` heap rewrite. But that filtering wasn't applied to the associated toast table if any, leading to possible errors when rewriting a table that's being published.

- Ensure that walreceiver processes create all required archive notification files before exiting (Fujii Masao)

If a walreceiver exited exactly at a WAL segment boundary, it failed to make a notification file for the last-received segment, thus delaying archiving of that segment on the standby.

- Avoid trying to lock the `OLD` and `NEW` pseudo-relations in a rule that uses `SELECT FOR UPDATE` (Masahiko Sawada, Tom Lane)
- Fix parser's processing of aggregate `FILTER` clauses (Tom Lane)

If the `FILTER` expression is a plain boolean column, the semantic level of the aggregate could be mis-determined, leading to not-per-spec behavior. If the `FILTER` expression is itself a boolean-returning aggregate, an error should be thrown but was not, likely resulting in a crash at execution.

- Avoid trying to clean up LLVM state after an error within LLVM (Andres Freund, Justin Pryzby)

This prevents a likely crash during backend exit after a fatal LLVM error.

- Avoid null-pointer-dereference crash when dropping a role that owns objects being dropped concurrently (Álvaro Herrera)
- Prevent “snapshot reference leak” warning when `lo_export()` or a related function fails (Heikki Linnakangas)
- Ensure that scans of SP-GiST indexes are counted in the statistics views (Tom Lane)

Incrementing the number-of-index-scans counter was overlooked in the SP-GiST code, although per-tuple counters were advanced correctly.

- Recalculate relevant wait intervals if `recovery_min_apply_delay` is changed during recovery (Soumyadeep Chakraborty, Ashwin Agrawal)
- Fix infinite loop if a `simplehash.h` hash table reaches  $2^{32}$  elements (Yura Sokolov)

It seems unlikely that this bug has been hit in practice, as it would require `work_mem` settings of hundreds of gigabytes for existing uses of `simplehash.h`.

- Reduce memory consumption during calculation of extended statistics (Justin Pryzby, Tomas Vondra)
- Fix `ecpg` to recover correctly after `malloc()` failure while establishing a connection (Michael Paquier)
- Fix misevaluation of stable functions called in the arguments of a PL/pgSQL `CALL` statement (Tom Lane)

They were being called with an out-of-date snapshot, so that they would not see any database changes made since the start of the session's top-level command.

- Allow `EXIT` out of the outermost block in a PL/pgSQL routine (Tom Lane)

If the routine does not require an explicit `RETURN`, this usage should be valid, but it was rejected.

- Remove `pg_ctl`'s hard-coded limits on the total length of generated commands (Phil Krylov)

For example, this removes a restriction on how many command-line options can be passed through to the postmaster. Individual path names that `pg_ctl` deals with, such as the postmaster executable's name or the data directory name, are still limited to `MAXPGPATH` bytes in most cases.

- Fix `pg_dump` to dump non-global default privileges correctly (Neil Chen, Masahiko Sawada)

If a global (unrestricted) `ALTER DEFAULT PRIVILEGES` command revoked some present-by-default privilege, for example `EXECUTE` for functions, and then a restricted `ALTER DEFAULT PRIVILEGES` command granted that privilege again for a selected role or schema, `pg_dump` failed to dump the restricted privilege grant correctly.

- Make `pg_dump` acquire shared lock on partitioned tables that are to be dumped (Tom Lane)

This oversight was usually pretty harmless, since once `pg_dump` has locked any of the leaf partitions, that would suffice to prevent significant DDL on the partitioned table itself. However problems could ensue when dumping a childless partitioned table, since no relevant lock would be held.

- Improve `pg_dump`'s performance by avoiding making per-table queries for RLS policies, and by avoiding repetitive calls to `format_type()` (Tom Lane)

These changes provide only marginal improvement when dumping from a local server, but a dump from a remote server can benefit substantially due to fewer network round-trips.

- Fix crash in `pg_dump` when attempting to dump trigger definitions from a pre-8.3 server (Tom Lane)
- Fix incorrect filename in `pg_restore`'s error message about an invalid large object TOC file (Daniel Gustafsson)
- Fix failure of `contrib/btree_gin` indexes on `"char"` (not `char(n)`) columns, when an indexscan using the `<` or `<=` operator is performed (Tom Lane)

Such an indexscan failed to return all the entries it should.

- Change `contrib/pg_stat_statements` to read its "query texts" file in units of at most 1GB (Tom Lane)

Such large query text files are very unusual, but if they do occur, the previous coding would fail on Windows 64 (which rejects individual read requests of more than 2GB).

- Fix null-pointer crash when `contrib/postgres_fdw` tries to report a data conversion error (Tom Lane)
- Add spinlock support for the RISC-V architecture (Marek Szuba)

This is essential for reasonable performance on that platform.

- Support OpenSSL 3.0.0 (Peter Eisentraut, Daniel Gustafsson, Michael Paquier)
- Set correct type identifier on OpenSSL BIO (I/O abstraction) objects created by PostgreSQL (Itamar Gafni)

This oversight probably only matters for code that is doing tasks like auditing the OpenSSL installation. But it's nominally a violation of the OpenSSL API, so fix it.

- Make `pg_regexec()` robust against an out-of-range `search_start` parameter (Tom Lane)

Return `REG_NOMATCH`, instead of possibly crashing, when `search_start` is past the end of the string. This case is probably unreachable within core PostgreSQL, but extensions might be more careless about the parameter value.

- Ensure that `GetSharedSecurityLabel()` can be used in a newly-started session that has not yet built its critical relation cache entries (Jeff Davis)
- Use the CLDR project's data to map Windows time zone names to IANA time zones (Tom Lane)

When running on Windows, `initdb` attempts to set the new cluster's `timezone` parameter to the IANA time zone matching the system's prevailing time zone. We were using a mapping table that we'd generated years ago and updated only fitfully; unsurprisingly, it contained a number of errors as well as omissions of recently-added zones. It turns out that CLDR has been tracking the most appropriate mappings, so start using their data. This change will not affect any existing installation, only newly-initialized clusters.

- Update time zone data files to `tzdata` release 2021e for DST law changes in Fiji, Jordan, Palestine, and Samoa, plus historical corrections for Barbados, Cook Islands, Guyana, Niue, Portugal, and Tonga.

Also, the Pacific/Enderbury zone has been renamed to Pacific/Kanton. Also, the following zones have been merged into nearby, more-populous zones whose clocks have agreed with them since 1970: Africa/Accra, America/Atikokan, America/Blanc-Sablon, America/Creston, America/Curacao, America/Nassau, America/Port\_of\_Spain, Antarctica/DumontDURville, and Antarctica/Syowa. In all these cases, the previous zone name remains as an alias.

## E.33. Release 11.13

**Release date:** 2021-08-12

This release contains a variety of fixes from 11.12. For information about new features in major release 11, see [Section E.46](#).

### E.33.1. Migration to Version 11.13

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.11, see [Section E.35](#).

### E.33.2. Changes

- Fix mis-planning of repeated application of a projection step (Tom Lane)

The planner could create an incorrect plan in cases where two `ProjectionPaths` were stacked on top of each other. The only known way to trigger that situation involves parallel sort operations, but there may be other instances. The result would be crashes or incorrect query results. Disclosure of server memory contents is also possible. (CVE-2021-3677)

- Disallow SSL renegotiation more completely (Michael Paquier)

SSL renegotiation has been disabled for some time, but the server would still cooperate with a client-initiated renegotiation request. A maliciously crafted renegotiation request could result in a server crash (see OpenSSL issue CVE-2021-3449). Disable the feature altogether on OpenSSL versions that permit doing so, which are 1.1.0h and newer.

- Restore the Portal-level snapshot after `COMMIT` or `ROLLBACK` within a procedure (Tom Lane)

This change fixes cases where an attempt to fetch a toasted value immediately after `COMMIT/ROLLBACK` would fail with errors like “no known snapshots” or “missing chunk number 0 for toast value”.

Some extensions may attempt to execute SQL code outside of any Portal. They are responsible for ensuring that an outer snapshot exists before doing so. Previously, not providing a snapshot might work or it might not; now it will consistently fail with “cannot execute SQL without an outer snapshot or portal”.

- Avoid misbehavior when persisting the output of a cursor that's reading a non-stable query (Tom Lane)

Previously, we'd always rewind and re-read the whole query result, possibly getting results different from the earlier execution, causing great confusion later. For a `NO SCROLL` cursor, we can fix this by only storing the not-yet-read portion of the query output, which is sufficient since a `NO SCROLL` cursor can't be backed up. Cursors with the `SCROLL` option remain at hazard, but that was already documented to be an unsafe option to use with a non-stable query. Make those documentation warnings stronger.

Also force `NO SCROLL` mode for the implicit cursor used by a PL/pgSQL `FOR-over-query` loop, to avoid this type of problem when persisting such a cursor during an intra-procedure commit.

- Reject `SELECT ... GROUP BY GROUPING SETS (( )) FOR UPDATE` (Tom Lane)

This should be disallowed, just as `FOR UPDATE` with a plain `GROUP BY` is disallowed, but the test for that failed to handle empty grouping sets correctly. The end result would be a null-pointer dereference in the executor.

- Reject cases where a query in `WITH` rewrites to just `NOTIFY` (Tom Lane)

Such cases previously crashed.

- In `numeric` multiplication, round the result rather than failing if it would have more than 16383 digits after the decimal point (Dean Rasheed)

- Fix corner-case errors and loss of precision when raising `numeric` values to very large powers (Dean Rasheed)
- Fix division-by-zero failure in `to_char()` with `EEEE` format and a `numeric` input value less than  $10^{(-1001)}$  (Dean Rasheed)
- Fix `pg_size_pretty(bigint)` to round negative values consistently with the way it rounds positive ones (and consistently with the `numeric` version) (Dean Rasheed, David Rowley)
- Make `pg_filenode_relation(0, 0)` return NULL rather than failing (Justin Pryzby)
- Make `ALTER EXTENSION` lock the extension when adding or removing a member object (Tom Lane)

The previous coding allowed `ALTER EXTENSION ADD/DROP` to occur concurrently with `DROP EXTENSION`, leading to a crash or corrupt catalog entries.

- Fix `ALTER SUBSCRIPTION` to reject an empty slot name (Japin Li)
- When cloning a partitioned table's triggers to a new partition, ensure that their enabled status is copied (Álvaro Herrera)
- Avoid alias conflicts in queries generated for `REFRESH MATERIALIZED VIEW CONCURRENTLY` (Tom Lane, Bharath Rupireddy)

This command failed on materialized views containing columns with certain names, notably `mv` and `newdata`.

- Fix `PREPARE TRANSACTION` to check correctly for conflicting session-lifespan and transaction-lifespan locks (Tom Lane)

A transaction cannot be prepared if it has both session-lifespan and transaction-lifespan locks on the same advisory-lock ID value. This restriction was not fully checked, which could lead to a PANIC during `PREPARE TRANSACTION`.

- Fix misbehavior of `DROP OWNED BY` when the target role is listed more than once in an RLS policy (Tom Lane)
- Skip unnecessary error tests when removing a role from an RLS policy during `DROP OWNED BY` (Tom Lane)

Notably, this fixes some cases where it was necessary to be a superuser to use `DROP OWNED BY`.

- Don't store a "fast default" when adding a column to a foreign table (Andrew Dunstan)

The fast default is useless since no local heap storage exists for such a table, but it confused subsequent operations. In addition to suppressing creation of such catalog entries in `ALTER TABLE` commands, adjust the downstream code to cope when one is incorrectly present.

- Allow index state flags to be updated transactionally (Michael Paquier, Andrey Lepikhov)

This avoids failures when dealing with index predicates that aren't really immutable. While that's not considered a supported case, the original reason for using a non-transactional update here is long gone, so we may as well change it.

- Avoid corrupting the plan cache entry when `CREATE DOMAIN` or `ALTER DOMAIN` appears in a cached plan (Tom Lane)
- Make walsenders show their latest replication commands in `pg_stat_activity` (Tom Lane)

Previously, a walsender would show its latest SQL command, which was confusing if it's now doing some replication operation instead. Now we show replication-protocol commands on the same footing as SQL commands.

- Make `pg_settings.pending_restart` show as true when the pertinent entry in `postgresql.conf` has been removed (Álvaro Herrera)

`pending_restart` correctly showed the case where an entry that cannot be changed without a post-master restart has been modified, but not where the entry had been removed altogether.

- Fix corner-case failure of a new standby to follow a new primary (Dilip Kumar, Robert Haas)

Under a narrow combination of conditions, the standby could wind up trying to follow the wrong WAL timeline.

- Update minimum recovery point when WAL replay of a transaction abort record causes file truncation (Fujii Masao)

File truncation is irreversible, so it's no longer safe to stop recovery at a point earlier than that record. The corresponding case for transaction commit was fixed years ago, but this one was overlooked.

- In walreceivers, avoid attempting catalog lookups after an error (Masahiko Sawada, Bharath Rupireddy)
- Ensure that a standby server's startup process will respond to a shutdown signal promptly while waiting for WAL to arrive (Fujii Masao, Soumyadeep Chakraborty)
- Correctly clear shared state after failing to become a member of a transaction commit group (Amit Kapila)

Given the right timing, this could cause an assertion failure when some later session re-uses the same PGPROC object.

- Add locking to avoid reading incorrect relmapper data in the face of a concurrent write from another process (Heikki Linnakangas)
- Improve checks for violations of replication protocol (Tom Lane)

Logical replication workers frequently used Asserts to check for cases that could be triggered by invalid or out-of-order replication commands. This seems unwise, so promote these tests to regular error checks.

- Fix deadlock when multiple logical replication workers try to truncate the same table (Peter Smith, Haiying Tang)
- Fix error cases and memory leaks in logical decoding of speculative insertions (Dilip Kumar)
- Avoid leaving an invalid record-type hash table entry behind after an error (Sait Talha Nisanci)

This could lead to later crashes or memory leakage.

- Fix plan cache reference leaks in some error cases in `CREATE TABLE ... AS EXECUTE` (Tom Lane)
- Fix race condition in code for sharing tuple descriptors across parallel workers (Thomas Munro)

Given the right timing, a crash could result.

- Fix possible race condition when releasing `BackgroundWorkerSlots` (Tom Lane)

It's likely that this doesn't fix any observable bug on Intel hardware, but machines with weaker memory ordering rules could have problems.

- Fix latent crash in sorting code (Ronan Dunklau)

One code path could attempt to free a null pointer. The case appears unreachable in the core server's use of sorting, but perhaps it could be triggered by extensions.

- Prevent infinite loops in SP-GiST index insertion (Tom Lane)

In the event that `INCLUDE` columns take up enough space to prevent a leaf index tuple from ever fitting on a page, the `text_ops` operator class would get into an infinite loop vainly trying to make the tuple fit. While pre-v11 versions don't have `INCLUDE` columns, back-patch this anti-looping fix to them anyway, as it seems like a good defense against bugs in operator classes.

- Ensure that SP-GiST index insertion can be terminated by a query cancel request (Tom Lane, Álvaro Herrera)
- Fix uninitialized-variable bug that could cause PL/pgSQL to act as though an `INTO` clause specified `STRICT`, even though it didn't (Tom Lane)
- Don't abort the process for an out-of-memory failure in libpq's printing functions (Tom Lane)
- In `ecpg`, allow the `numeric` value `INT_MIN` (usually -2147483648) to be converted to integer (John Naylor)
- In `psql` and other client programs, avoid overrunning the ends of strings when dealing with invalidly-encoded data (Tom Lane)

An incorrectly-encoded multibyte character near the end of a string could cause various processing loops to run past the string's terminating NUL, with results ranging from no detectable issue to a program crash, depending on what happens to be in the following memory. This is reminiscent of CVE-2006-2313, although these particular cases do not appear to have interesting security consequences.

- Fix `pg_dump` to correctly handle triggers on partitioned tables whose enabled status is different from their parent triggers' status (Justin Pryzby, Álvaro Herrera)
- Avoid “invalid creation date in header” warnings observed when running `pg_restore` on an archive file created in a different time zone (Tom Lane)
- Make `pg_upgrade` carry forward the old installation's `oldestXID` value (Bertrand Drouvot)

Previously, the new installation's `oldestXID` was set to a value old enough to (usually) force immediate anti-wraparound autovacuuming. That's not desirable from a performance standpoint; what's worse, installations using large values of `autovacuum_freeze_max_age` could suffer unwanted forced shutdowns soon after an upgrade.

- Extend `pg_upgrade` to detect and warn about extensions that should be upgraded (Bruce Momjian)

A script file is now produced containing the `ALTER EXTENSION UPDATE` commands needed to bring extensions up to the versions that are considered default in the new installation.

- Avoid problems when switching `pg_receivewal` between compressed and non-compressed WAL storage (Michael Paquier)
- In `contrib/postgres_fdw`, avoid attempting catalog lookups after an error (Tom Lane)

While this usually worked, it's not very safe since the error might have been one that made catalog access nonfunctional. A side effect of the fix is that messages about data conversion errors will now mention the query's table and column aliases (if used) rather than the true underlying name of a foreign table or column.

- Improve the isolation-test infrastructure (Tom Lane, Michael Paquier)

Allow isolation test steps to be annotated to show the expected completion order. This allows getting stable results from otherwise-racy test cases, without the long delays that we previously used (not entirely successfully) to fend off race conditions. Allow non-quoted identifiers as isolation test session/step names (formerly, all such names had to be double-quoted). Detect and warn about unused steps in isolation tests. Improve display of query results in isolation tests. Remove isolation-tester's “dry-run” mode. Remove memory leaks in `isolationtester` itself.

- Reduce overhead of cache-clobber testing (Tom Lane)
- Fix PL/Python's regression tests to pass with Python 3.10 (Honza Horak)
- Make `printf("%s", NULL)` print `(null)` instead of crashing (Tom Lane)

This should improve server robustness in corner cases, and it syncs our `printf` implementation with common libraries.

- Fix incorrect log message when point-in-time recovery stops at a `ROLLBACK PREPARED` record (Simon Riggs)
- Improve `ALTER TABLE`'s messages for wrong-relation-kind errors (Kyotaro Horiguchi)
- Clarify error messages referring to “non-negative” values (Bharath Rupireddy)
- Fix configure to work with OpenLDAP 2.5, which no longer has a separate `libldap_r` library (Adrian Ho, Tom Lane)

If there is no `libldap_r` library, we now silently assume that `libldap` is thread-safe.

- Add new make targets `world-bin` and `install-world-bin` (Andrew Dunstan)

These are the same as `world` and `install-world` respectively, except that they do not build or install the documentation.

- Fix make rule for TAP tests (`prove_installcheck`) to work in PGXS usage (Andrew Dunstan)
- Adjust JIT code to prepare for forthcoming LLVM API change (Thomas Munro, Andres Freund)

LLVM 13 has made an incompatible API change that will cause crashing of our previous JIT compiler.

- Avoid assuming that strings returned by GSSAPI libraries are null-terminated (Tom Lane)

The GSSAPI spec provides for a string pointer and length. It seems that in practice the next byte after the string is usually zero, so that our previous coding didn't actually fail; but we do have a report of AddressSanitizer complaints.

- Enable building with GSSAPI on MSVC (Michael Paquier)

Fix various incompatibilities with modern Kerberos builds.

- In MSVC builds, include `--with-pgport` in the set of configure options reported by `pg_config`, if it had been specified (Andrew Dunstan)

## E.34. Release 11.12

**Release date:** 2021-05-13

This release contains a variety of fixes from 11.11. For information about new features in major release 11, see [Section E.46](#).

### E.34.1. Migration to Version 11.12

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.11, see [Section E.35](#).

### E.34.2. Changes

- Prevent integer overflows in array subscripting calculations (Tom Lane)

The array code previously did not complain about cases where an array's lower bound plus length overflows an integer. This resulted in later entries in the array becoming inaccessible (since their subscripts could not be written as integers), but more importantly it confused subsequent assignment operations. This could lead to memory overwrites, with ensuing crashes or unwanted data modifications. (CVE-2021-32027)

- Fix mishandling of “junk” columns in `INSERT ... ON CONFLICT ... UPDATE` target lists (Tom Lane)

If the `UPDATE` list contains any multi-column sub-selects (which give rise to junk columns in addition to the results proper), the `UPDATE` path would end up storing tuples that include the values of the extra junk columns. That's fairly harmless in the short run, but if new columns are added to the ta-

ble then the values would become accessible, possibly leading to malfunctions if they don't match the datatypes of the added columns.

In addition, in versions supporting cross-partition updates, a cross-partition update triggered by such a case had the reverse problem: the junk columns were removed from the target list, typically causing an immediate crash due to malfunction of the multi-column sub-select mechanism. (CVE-2021-32028)

- Fix possibly-incorrect computation of `UPDATE ... RETURNING` outputs for joined cross-partition updates (Amit Langote, Etsuro Fujita)

If an `UPDATE` for a partitioned table caused a row to be moved to another partition with a physically different row type (for example, one with a different set of dropped columns), computation of `RETURNING` results for that row could produce errors or wrong answers. No error is observed unless the `UPDATE` involves other tables being joined to the target table. (CVE-2021-32029)

- Fix adjustment of constraint deferrability properties in partitioned tables (Álvaro Herrera)

When applied to a foreign-key constraint of a partitioned table, `ALTER TABLE ... ALTER CONSTRAINT` failed to adjust the `DEFERRABLE` and/or `INITIALLY DEFERRED` markings of the constraints and triggers of leaf partitions. This led to unexpected behavior of such constraints. After updating to this version, any misbehaving partitioned tables can be fixed by executing a new `ALTER` command to set the desired properties.

This change also disallows applying such an `ALTER` directly to the constraints of leaf partitions. The only supported case is for the whole partitioning hierarchy to have identical constraint properties, so such `ALTERS` must be applied at the partition root.

- Forbid marking an identity column as nullable (Vik Fearing)

`GENERATED ... AS IDENTITY` implies `NOT NULL`, so don't allow it to be combined with an explicit `NULL` specification.

- Allow `ALTER ROLE/DATABASE ... SET` to set the `role`, `session_authorization`, and `temp_buffers` parameters (Tom Lane)

Previously, over-eager validity checks might reject these commands, even if the values would have worked when used later. This created a command ordering hazard for dump/reload and upgrade scenarios.

- Fix bug with coercing the result of a `COLLATE` expression to a non-collatable type (Tom Lane)

This led to a parse tree in which the `COLLATE` appears to be applied to a non-collatable value. While that normally has no real impact (since `COLLATE` has no effect at runtime), it was possible to construct views that would be rejected during dump/reload.

- Disallow calling window functions and procedures via the “fast path” wire protocol message (Tom Lane)

Only plain functions are supported here. While trying to call an aggregate function failed already, calling a window function would crash, and calling a procedure would work only if the procedure did no transaction control.

- Extend `pg_identify_object_as_address()` to support event triggers (Joel Jacobson)
- Fix `to_char()`'s handling of Roman-numeral month format codes with negative intervals (Julien Rouhaud)

Previously, such cases would usually cause a crash.

- Check that the argument of `pg_import_system_collations()` is a valid schema OID (Tom Lane)
- Fix use of uninitialized value while parsing an `\{m,n\}` quantifier in a BRE-mode regular expression (Tom Lane)

This error could cause the quantifier to act non-greedy, that is behave like an  $\{m, n\}^?$  quantifier would do in full regular expressions.

- Don't ignore system columns when estimating the number of groups using extended statistics (Tomas Vondra)

This led to strange estimates for queries such as `SELECT ... GROUP BY a, b, ctid`.

- Avoid divide-by-zero when estimating selectivity of a regular expression with a very long fixed prefix (Tom Lane)

This typically led to a NaN selectivity value, causing assertion failures or strange planner behavior.

- Fix access-off-the-end-of-the-table error in BRIN index bitmap scans (Tomas Vondra)

If the page range size used by a BRIN index isn't a power of two, there were corner cases in which a bitmap scan could try to fetch pages past the actual end of the table, leading to "could not open file" errors.

- Avoid incorrect timeline change while recovering uncommitted two-phase transactions from WAL (Soumyadeep Chakraborty, Jimmy Yih, Kevin Yeap)

This error could lead to subsequent WAL records being written under the wrong timeline ID, leading to consistency problems, or even complete failure to be able to restart the server, later on.

- Ensure that locks are released while shutting down a standby server's startup process (Fujii Masao)

When a standby server is shut down while still in recovery, some locks might be left held. This causes assertion failures in debug builds; it's unclear whether any serious consequence could occur in production builds.

- Fix crash when a logical replication worker does `ALTER SUBSCRIPTION REFRESH` (Peter Smith)

The core code won't do this, but a replica trigger could.

- Ensure we default to `wal_sync_method = fdatasync` on recent FreeBSD (Thomas Munro)

FreeBSD 13 supports `open_datasync`, which would normally become the default choice. However, it's unclear whether that is actually an improvement for Postgres, so preserve the existing default for now.

- Ensure we finish cleaning up when interrupted while detaching a DSM segment (Thomas Munro)

This error could result in temporary files not being cleaned up promptly after a parallel query.

- Fix memory leak while initializing server's SSL parameters (Michael Paquier)

This is ordinarily insignificant, but if the postmaster is repeatedly sent SIGHUP signals, the leak can build up over time.

- Fix assorted minor memory leaks in the server (Tom Lane, Andres Freund)
- Fix failure when a PL/pgSQL `DO` block makes use of both composite-type variables and transaction control (Tom Lane)

Previously, such cases led to errors about leaked tuple descriptors.

- Prevent infinite loop in libpq if a ParameterDescription message with a corrupt length is received (Tom Lane)
- When `initdb` prints instructions about how to start the server, make the path shown for `pg_ctl` use backslash separators on Windows (Nitin Jadhav)
- Fix `psql` to restore the previous behavior of `\connect service=something` (Tom Lane)

A previous bug fix caused environment variables (such as `PGPORT`) to override entries in the service file in this context. Restore the previous behavior, in which the priority is the other way around.

- Fix race condition in detection of file modification by `psql's \e` and related commands (Laurenz Albe)

A very fast typist could fool the code's file-timestamp-based detection of whether the temporary edit file was changed.

- Fix missed file version check in `pg_restore` (Tom Lane)

When reading a custom-format archive from a non-seekable source, `pg_restore` neglected to check the archive version. If it was fed a newer archive version than it can support, it would fail messily later on.

- Add some more checks to `pg_upgrade` for user tables containing non-upgradable data types (Tom Lane)

Fix detection of some cases where a non-upgradable data type is embedded within a container type (such as an array or range). Also disallow upgrading when user tables contain columns of system-defined composite types, since those types' OIDs are not stable across versions.

- Fix `pg_waldump` to count `XACT` records correctly when generating per-record statistics (Kyotaro Horiguchi)
- Fix `contrib/amcheck` to not complain about the tuple flags `HEAP_XMAX_LOCK_ONLY` and `HEAP_KEYS_UPDATED` both being set (Julien Rouhaud)

This is a valid state after `SELECT FOR UPDATE`.

- Adjust `VPATH` build rules to support recent Oracle Developer Studio compiler versions (Noah Misch)
- Fix testing of PL/Python for Python 3 on Solaris (Noah Misch)

## E.35. Release 11.11

**Release date:** 2021-02-11

This release contains a variety of fixes from 11.10. For information about new features in major release 11, see [Section E.46](#).

### E.35.1. Migration to Version 11.11

A dump/restore is not required for those running 11.X.

However, see the second changelog item below, which describes cases in which reindexing indexes after the upgrade may be advisable.

Also, if you are upgrading from a version earlier than 11.6, see [Section E.40](#).

### E.35.2. Changes

- Fix information leakage in constraint-violation error messages (Heikki Linnakangas)

If an `UPDATE` command attempts to move a row to a different partition but finds that it violates some constraint on the new partition, and the columns in that partition are in different physical positions than in the parent table, the error message could reveal the contents of columns that the user does not have `SELECT` privilege on. (CVE-2021-3393)

- Fix `CREATE INDEX CONCURRENTLY` to wait for concurrent prepared transactions (Andrey Borodin)

At the point where `CREATE INDEX CONCURRENTLY` waits for all concurrent transactions to complete so that it can see rows they inserted, it must also wait for all prepared transactions to complete, for

the same reason. Its failure to do so meant that rows inserted by prepared transactions might be omitted from the new index, causing queries relying on the index to miss such rows. In installations that have enabled prepared transactions (`max_prepared_transactions > 0`), it's recommended to reindex any concurrently-built indexes in case this problem occurred when they were built.

- Avoid crash when a `CALL` or `DO` statement that performs a transaction rollback is executed via extended query protocol (Thomas Munro, Tom Lane)

In PostgreSQL 13, this case reliably caused a null-pointer dereference. In earlier versions the bug seems to have no visible symptoms, but it's not quite clear that it could never cause a problem.

- Fix partition pruning logic to handle asymmetric hash partition sets (Tom Lane)

If a hash-partitioned table has unequally-sized partitions (that is, varying modulus values), or it lacks partitions for some remainder values, then the planner's pruning logic could mistakenly conclude that some partitions don't need to be scanned, leading to failure to find rows that the query should find.

- Avoid incorrect results when `WHERE CURRENT OF` is applied to a cursor whose plan contains a `MergeAppend` node (Tom Lane)

This case is unsupported (in general, a cursor using `ORDER BY` is not guaranteed to be simply updatable); but the code previously did not reject it, and could silently give false matches.

- Fix crash when `WHERE CURRENT OF` is applied to a cursor whose plan contains a custom scan node (David Geier)
- Fix planner's handling of a placeholder that is computed at some join level and used only at that same level (Tom Lane)

This oversight could lead to “failed to build any *N*-way joins” planner errors.

- Be more careful about whether index AMs support mark/restore (Andrew Gierth)

This prevents errors about missing support functions in rare edge cases.

- Adjust settings to make it more difficult to run out of DSM slots during heavy usage of parallel queries (Thomas Munro)
- Fix overestimate of the amount of shared memory needed for parallel queries (Takayuki Tsunakawa)
- Fix `ALTER DEFAULT PRIVILEGES` to handle duplicated arguments safely (Michael Paquier)

Duplicate role or schema names within the same command could lead to “tuple already updated by self” errors or unique-constraint violations.

- Flush ACL-related caches when `pg_authid` changes (Noah Misch)

This change ensures that permissions-related decisions will promptly reflect the results of `ALTER ROLE ... [NO] INHERIT`.

- Prevent misprocessing of ambiguous `CREATE TABLE LIKE` clauses (Tom Lane)

A `LIKE` clause is re-examined after initial creation of the new table, to handle importation of indexes and such. It was possible for this re-examination to find a different table of the same name, causing unexpected behavior; one example is where the new table is a temporary table of the same name as the `LIKE` target.

- Rearrange order of operations in `CREATE TABLE LIKE` so that indexes are cloned before building foreign key constraints (Tom Lane)

This fixes the case where a self-referential foreign key constraint declared in the outer `CREATE TABLE` depends on an index that's coming from the `LIKE` clause.

- Disallow `CREATE STATISTICS` on system catalogs (Tomas Vondra)

- Disallow converting an inheritance child table to a view (Tom Lane)
- Ensure that disk space allocated for a dropped relation is released promptly at commit (Thomas Munro)

Previously, if the dropped relation spanned multiple 1GB segments, only the first segment was truncated immediately. Other segments were simply unlinked, which doesn't authorize the kernel to release the storage so long as any other backends still have the files open.

- Prevent dropping a tablespace that is referenced by a partitioned relation, but is not used for any actual storage (Álvaro Herrera)

Previously this was allowed, but subsequent operations on the partitioned relation would fail.

- Fix handling of backslash-escaped multibyte characters in `COPY FROM` (Heikki Linnakangas)

A backslash followed by a multibyte character was not handled correctly. In some client character encodings, this could lead to misinterpreting part of a multibyte character as a field separator or end-of-copy-data marker.

- Avoid preallocating executor hash tables in `EXPLAIN` without `ANALYZE` (Alexey Bashtanov)
- Fix recently-introduced race conditions in `LISTEN/NOTIFY` queue handling (Tom Lane)

A newly-listening backend could attempt to read SLRU pages that were in process of being truncated, possibly causing an error.

The queue tail pointer could become set to a value that's not equal to the queue position of any backend, resulting in effective disabling of the queue truncation logic. Continued use of `NOTIFY` then led to queue-fill warnings, and eventually to inability to send any more notifies until the server is restarted.

- Allow the `jsonb` concatenation operator to handle all combinations of JSON data types (Tom Lane)

We can concatenate two JSON objects or two JSON arrays. Handle other cases by wrapping non-array inputs in one-element arrays, then performing an array concatenation. Previously, some combinations of inputs followed this rule but others arbitrarily threw an error.

- Fix use of uninitialized value while parsing a `*` quantifier in a BRE-mode regular expression (Tom Lane)

This error could cause the quantifier to act non-greedy, that is behave like a `*?` quantifier would do in full regular expressions.

- Fix numeric `power()` for the case where the exponent is exactly `INT_MIN` (-2147483648) (Dean Rasheed)

Previously, a result with no significant digits was produced.

- Fix integer-overflow cases in `substring()` functions (Tom Lane, Pavel Stehule)

If the specified starting index and length overflow an integer when added together, `substring()` misbehaved, either throwing a bogus “negative substring length” error for a case that should succeed, or failing to complain that a negative length is negative (and instead returning the whole string, in most cases).

- Prevent possible data loss from incorrect detection of the wraparound point of an SLRU log (Noah Misch)

The wraparound point typically falls in the middle of a page, which must be rounded off to a page boundary, and that was not done correctly. No issue could arise unless an installation had gotten to within one page of SLRU overflow, which is unlikely in a properly-functioning system. If this did happen, it would manifest in later “apparent wraparound” or “could not access status of transaction” errors.

- Fix memory leak in walsender processes while sending new snapshots for logical decoding (Amit Kapila)
- Fix walsender to accept additional commands after terminating replication (Jeff Davis)
- Ensure detection of deadlocks between hot standby backends and the startup (WAL-application) process (Fujii Masao)

The startup process did not run the deadlock detection code, so that in situations where the startup process is last to join a circular wait situation, the deadlock might never be recognized.

- Ensure that unserviced requests for background workers are cleaned up when the postmaster begins a “smart” or “fast” shutdown sequence (Tom Lane)

Previously, there was a race condition whereby a child process that had requested a background worker just before shutdown could wait indefinitely, preventing shutdown from completing.

- Fix portability problem in parsing of `recovery_target_xid` values (Michael Paquier)

The target XID is potentially 64 bits wide, but it was parsed with `strtoul()`, causing misbehavior on platforms where `long` is 32 bits (such as Windows).

- Avoid trying to use parallel index build in a standalone backend (Yulin Pei)
- Allow index AMs to support included columns without necessarily supporting multiple key columns (Tom Lane)
- Avoid assertion failure during parallel aggregation of an aggregate with a non-strict deserialization function (Andrew Gierth)

No such aggregate functions exist in core PostgreSQL, but some extensions such as PostGIS provide some. The mistake is harmless anyway in a non-assert build.

- Avoid assertion failure in `pg_get_functiondef()` when examining a function with a `TRANSFORM` option (Tom Lane)
- Fix data structure misallocation in PL/pgSQL's `CALL` statement (Tom Lane)

A `CALL` in a PL/pgSQL procedure, to another procedure that has OUT parameters, would fail if the called procedure did a `COMMIT` or `ROLLBACK`.

- In `psql`, re-allow including a password in a `connection_string` argument of a `\connect` command (Tom Lane)

This used to work, but a recent bug fix caused the password to be ignored (resulting in prompting for a password).

- Fix assorted bugs in `psql`'s `\help` command (Kyotaro Horiguchi, Tom Lane)

`\help` with two argument words failed to find a command description using only the first word, for example `\help reset all` should show the help for `RESET` but did not. Also, `\help` often failed to invoke the pager when it should. It also leaked memory.

- In `pg_dump`, ensure that the restore script runs `ALTER PUBLICATION ADD TABLE` commands as the owner of the publication, and similarly runs `ALTER INDEX ATTACH PARTITION` commands as the owner of the partitioned index (Tom Lane)

Previously, these commands would be run by the role that started the restore script; which will usually work, but in corner cases that role might not have adequate permissions.

- Fix `pg_dump` to handle `WITH GRANT OPTION` in an extension's initial privileges (Noah Misch)

If an extension's script creates an object and grants privileges on it with grant option, then later the user revokes such privileges, `pg_dump` would generate incorrect SQL for reproducing the situation. (Few if any extensions do this today.)

- In `pg_rewind`, ensure that all WAL is accounted for when rewinding a standby server (Ian Barwick, Heikki Linnakangas)
- In `pgbench`, disallow a digit as the first character of a variable name (Fabien Coelho)

This prevents trying to substitute variables into timestamp literal values, which may contain strings like `12:34`.

- Report the correct database name in connection failure error messages from some client programs (Álvaro Herrera)

If the database name was defaulted rather than given on the command line, `pg_dumpall`, `pgbench`, `oid2name`, and `vacuumlo` would produce misleading error messages after a connection failure.

- Fix memory leak in `contrib/auto_explain` (Japin Li)

Memory consumed while producing the `EXPLAIN` output was not freed until the end of the current transaction (for a top-level statement) or the end of the surrounding statement (for a nested statement). This was particularly a problem with `log_nested_statements` enabled.

- In `contrib/postgres_fdw`, avoid leaking open connections to remote servers when a user mapping or foreign server object is dropped (Bharath Rupireddy)

Open connections that depend on a dropped user mapping or foreign server can no longer be referenced, but formerly they were kept around anyway for the duration of the local session.

- In `contrib/pgcrypto`, check for error returns from OpenSSL's EVP functions (Michael Paquier)

We do not really expect errors here, but this change silences warnings from static analysis tools.

- Make `contrib/pg_prewarm` more robust when the cluster is shut down before prewarming is complete (Tom Lane)

Previously, `autoprewarm` would rewrite its status file with only the block numbers that it had managed to load so far, thus perhaps largely disabling the prewarm functionality in the next startup. Instead, suppress status file updates until the initial loading pass is complete.

- In `contrib/pg_trgm`'s GiST index support, avoid crash in the rare case that `picksplit` is called on exactly two index items (Andrew Gierth, Alexander Korotkov)
- Fix miscalculation of timeouts in `contrib/pg_prewarm` and `contrib/postgres_fdw` (Alexey Kondratov, Tom Lane)

The main loop in `contrib/pg_prewarm`'s `autoprewarm` parent process underestimated its desired sleep time by a factor of 1000, causing it to consume much more CPU than intended. When waiting for a result from a remote server, `contrib/postgres_fdw` overestimated the desired timeout by a factor of 1000 (though this error had been mitigated by imposing a clamp to 60 seconds).

Both of these errors stemmed from incorrectly converting seconds-and-microseconds to milliseconds. Introduce a new API `TimestampDifferenceMilliseconds()` to make it easier to get this right in the future.

- Improve `configure`'s heuristics for selecting `PG_SYSROOT` on macOS (Tom Lane)

The new method is more likely to produce desirable results when Xcode is newer than the underlying operating system. Choosing a `sysroot` that does not match the OS version may result in non-functional executables.

- While building on macOS, specify `-isysroot` in link steps as well as compile steps (James Hilliard)

This likewise improves the results when Xcode is out of sync with the operating system.

- Fix JIT compilation to be compatible with LLVM 11 and LLVM 12 (Andres Freund)
- Fix potential mishandling of references to boolean variables in JIT expression compilation (Andres Freund)

No field reports attributable to this have been seen, but it seems likely that it could cause problems on some architectures.

- Fix compile failure with ICU 68 and later (Tom Lane)
- Avoid `memcpy()` with a NULL source pointer and zero count during partitioned index creation (Álvaro Herrera)

While such a call is not known to cause problems in itself, some compilers assume that the arguments of `memcpy()` are never NULL, which could result in incorrect optimization of nearby code.

- Update time zone data files to tzdata release 2021a for DST law changes in Russia (Volgograd zone) and South Sudan, plus historical corrections for Australia, Bahamas, Belize, Bermuda, Ghana, Israel, Kenya, Nigeria, Palestine, Seychelles, and Vanuatu.

Notably, the Australia/Currie zone has been corrected to the point where it is identical to Australia/Hobart.

## E.36. Release 11.10

**Release date:** 2020-11-12

This release contains a variety of fixes from 11.9. For information about new features in major release 11, see [Section E.46](#).

### E.36.1. Migration to Version 11.10

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.6, see [Section E.40](#).

### E.36.2. Changes

- Block `DECLARE CURSOR ... WITH HOLD` and firing of deferred triggers within index expressions and materialized view queries (Noah Misch)

This is essentially a leak in the “security restricted operation” sandbox mechanism. An attacker having permission to create non-temporary SQL objects could parlay this leak to execute arbitrary SQL code as a superuser.

The PostgreSQL Project thanks Etienne Stalmans for reporting this problem. (CVE-2020-25695)

- Fix usage of complex connection-string parameters in `pg_dump`, `pg_restore`, `clusterdb`, `reindexdb`, and `vacuumdb` (Tom Lane)

The `-d` parameter of `pg_dump` and `pg_restore`, or the `--maintenance-db` parameter of the other programs mentioned, can be a “connection string” containing multiple connection parameters rather than just a database name. In cases where these programs need to initiate additional connections, such as parallel processing or processing of multiple databases, the connection string was forgotten and just the basic connection parameters (database name, host, port, and username) were used for the additional connections. This could lead to connection failures if the connection string included any other essential information, such as non-default SSL or GSS parameters. Worse, the connection might succeed but not be encrypted as intended, or be vulnerable to man-in-the-middle attacks that the intended connection parameters would have prevented. (CVE-2020-25694)

- When `psql`'s `\connect` command re-uses connection parameters, ensure that all non-overridden parameters from a previous connection string are re-used (Tom Lane)

This avoids cases where reconnection might fail due to omission of relevant parameters, such as non-default SSL or GSS options. Worse, the reconnection might succeed but not be encrypted as intended, or be vulnerable to man-in-the-middle attacks that the intended connection parameters

would have prevented. This is largely the same problem as just cited for `pg_dump` et al, although `psql`'s behavior is more complex since the user may intentionally override some connection parameters. (CVE-2020-25694)

- Prevent `psql`'s `\gset` command from modifying specially-treated variables (Noah Misch)

`\gset` without a prefix would overwrite whatever variables the server told it to. Thus, a compromised server could set specially-treated variables such as `PROMPT1`, giving the ability to execute arbitrary shell code in the user's session.

The PostgreSQL Project thanks Nick Cleaton for reporting this problem. (CVE-2020-25696)

- Prevent possible data loss from concurrent truncations of SLRU logs (Noah Misch)

This rare problem would manifest in later “apparent wraparound” or “could not access status of transaction” errors.

- Ensure that SLRU directories are properly `fsync`'d during checkpoints (Thomas Munro)

This prevents possible data loss in a subsequent operating system crash.

- Fix `ALTER ROLE` for users with the `BYPASSRLS` attribute (Tom Lane, Stephen Frost)

The `BYPASSRLS` attribute is only allowed to be changed by superusers, but other `ALTER ROLE` operations, such as password changes, should be allowed with only ordinary permission checks. The previous coding erroneously restricted all changes on such a role to superusers.

- Ensure that `ALTER TABLE ONLY ... ENABLE/DISABLE TRIGGER` does not recurse to child tables (Álvaro Herrera)

Previously the `ONLY` flag was ignored.

- Fix handling of expressions in `CREATE TABLE LIKE` with inheritance (Tom Lane)

If a `CREATE TABLE` command uses both `LIKE` and traditional inheritance, column references in `CHECK` constraints and expression indexes that came from a `LIKE` parent table tended to get mis-numbered, resulting in wrong answers and/or bizarre error messages. The same could happen in `GENERATED` expressions, in branches that have that feature.

- Disallow `DROP INDEX CONCURRENTLY` on a partitioned table (Álvaro Herrera, Michael Paquier)

This case failed anyway, but with a confusing error message.

- Allow `LOCK TABLE` to succeed on a self-referential view (Tom Lane)

It previously threw an error complaining about infinite recursion, but there seems no need to disallow the case.

- Fix off-by-one conversion of negative years to BC dates in `to_date()` and `to_timestamp()` (Dar Alathar-Yemen, Tom Lane)

Also, arrange for the combination of a negative year and an explicit “BC” marker to cancel out and produce AD.

- Ensure that standby servers will archive WAL timeline history files when `archive_mode` is set to `always` (Grigory Smolkin, Fujii Masao)

This oversight could lead to failure of subsequent PITR recovery attempts.

- Fix “cache lookup failed for relation 0” failures in logical replication workers (Tom Lane)

The real-world impact is small, since the failure is unlikely, and if it does happen the worker would just exit and be restarted.

- Prevent logical replication workers from sending redundant ping requests (Tom Lane)

- During “smart” shutdown, don't terminate background processes until all client (foreground) sessions are done (Tom Lane)

The previous behavior broke parallel query processing, since the postmaster would terminate parallel workers and refuse to launch any new ones. It also caused autovacuum to cease functioning, which could have dire long-term effects if the surviving client sessions make a lot of data changes.

- Avoid recursive consumption of stack space while processing signals in the postmaster (Tom Lane)

Heavy use of parallel processing has been observed to cause postmaster crashes due to too many concurrent signals requesting creation of a parallel worker process.

- Avoid running atexit handlers when exiting due to SIGQUIT (Kyotaro Horiguchi, Tom Lane)

Most server processes followed this practice already, but the archiver process was overlooked. Backends that were still waiting for a client startup packet got it wrong, too.

- Avoid misoptimization of subquery qualifications that reference apparently-constant grouping columns (Tom Lane)

A “constant” subquery output column isn't really constant if it is a grouping column that appears in only some of the grouping sets.

- Avoid failure when SQL function inlining changes the shape of a potentially-hashable subplan comparison expression (Tom Lane)
- While building or re-building an index, tolerate the appearance of new HOT chains due to concurrent updates (Anastasia Lubennikova, Álvaro Herrera)

This oversight could lead to “failed to find parent tuple for heap-only tuple” errors.

- Fix failure of parallel B-tree index scans when the index condition is unsatisfiable (James Hunter)
- Ensure that data is detoasted before being inserted into a BRIN index (Tomas Vondra)

Index entries are not supposed to contain out-of-line TOAST pointers, but BRIN didn't get that memo. This could lead to errors like “missing chunk number 0 for toast value NNN”. (If you are faced with such an error from an existing index, `REINDEX` should be enough to fix it.)

- Handle concurrent desummarization correctly during BRIN index scans (Alexander Lakhin, Álvaro Herrera)

Previously, if a page range was desummarized at just the wrong time, an index scan might falsely raise an error indicating index corruption.

- Fix rare “lost saved point in index” errors in scans of multicolumn GIN indexes (Tom Lane)
- Fix unportable use of `getnameinfo()` in `pg_hba_file_rules` view (Tom Lane)

On FreeBSD 11, and possibly other platforms, the view's `address` and `netmask` columns were always null due to this error.

- Avoid crash if `debug_query_string` is NULL when starting a parallel worker (Noah Misch)
- Fix use-after-free hazard when an event trigger monitors an `ALTER TABLE` operation (Jehan-Guil-laume de Rorthais)
- Fix incorrect error message about inconsistent moving-aggregate data types (Jeff Janes)
- Avoid lockup when a parallel worker reports a very long error message (Vignesh C)
- Avoid unnecessary failure when transferring very large payloads through shared memory queues (Markus Wanner)
- Fix incorrect handling of template function attributes in JIT code generation (Andres Freund)

This has been shown to cause crashes on `s390x`, and very possibly there are other cases on other platforms.

- Fix relation cache memory leaks with RLS policies (Tom Lane)
- Fix small memory leak when SIGHUP processing decides that a new GUC variable value cannot be applied without a restart (Tom Lane)
- Fix memory leaks in PL/pgsql's `CALL` processing (Pavel Stehule, Tom Lane)
- Make libpq support arbitrary-length lines in `.pgpass` files (Tom Lane)

This is mostly useful to allow using very long security tokens as passwords.

- In libpq for Windows, call `WSAStartup()` once per process and `WSACleanup()` not at all (Tom Lane, Alexander Lakhin)

Previously, libpq invoked `WSAStartup()` at connection start and `WSACleanup()` at connection cleanup. However, it appears that calling `WSACleanup()` can interfere with other program operations; notably, we have observed rare failures to emit expected output to stdout. There appear to be no ill effects from omitting the call, so do that. (This also eliminates a performance issue from repeated DLL loads and unloads when a program performs a series of database connections.)

- Fix ecpg library's per-thread initialization logic for Windows (Tom Lane, Alexander Lakhin)

Multi-threaded ecpg applications could suffer rare misbehavior due to incorrect locking.

- On Windows, make psql read the output of a backtick command in text mode, not binary mode (Tom Lane)

This ensures proper handling of newlines.

- Ensure that `pg_dump` collects per-column information about extension configuration tables (Fabrício de Royes Mello, Tom Lane)

Failure to do this led to crashes when specifying `--inserts`, or underspecified (though usually correct) `COPY` commands when using `COPY` to reload the tables' data.

- Make `pg_upgrade` check for pre-existence of tablespace directories in the target cluster (Bruce Momjian)
- Fix potential memory leak in `contrib/pgcrypto` (Michael Paquier)
- Add check for an unlikely failure case in `contrib/pgcrypto` (Daniel Gustafsson)
- Fix recently-added `timetz` test case so it works when the USA is not observing daylight savings time (Tom Lane)
- Update time zone data files to tzdata release 2020d for DST law changes in Fiji, Morocco, Palestine, the Canadian Yukon, Macquarie Island, and Casey Station (Antarctica); plus historical corrections for France, Hungary, Monaco, and Palestine.
- Sync our copy of the timezone library with IANA tzcode release 2020d (Tom Lane)

This absorbs upstream's change of `zic`'s default output option from “fat” to “slim”. That's just cosmetic for our purposes, as we continue to select the “fat” mode in pre-v13 branches. This change also ensures that `strftime()` does not change `errno` unless it fails.

## E.37. Release 11.9

**Release date:** 2020-08-13

This release contains a variety of fixes from 11.8. For information about new features in major release 11, see [Section E.46](#).

### E.37.1. Migration to Version 11.9

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.6, see [Section E.40](#).

### E.37.2. Changes

- Set a secure `search_path` in logical replication walsenders and apply workers (Noah Misch)

A malicious user of either the publisher or subscriber database could potentially cause execution of arbitrary SQL code by the role running replication, which is often a superuser. Some of the risks here are equivalent to those described in CVE-2018-1058, and are mitigated in this patch by ensuring that the replication sender and receiver execute with empty `search_path` settings. (As with CVE-2018-1058, that change might cause problems for under-qualified names used in replicated tables' DDL.) Other risks are inherent in replicating objects that belong to untrusted roles; the most we can do is document that there is a hazard to consider. (CVE-2020-14349)

- Make contrib modules' installation scripts more secure (Tom Lane)

Attacks similar to those described in CVE-2018-1058 could be carried out against an extension installation script, if the attacker can create objects in either the extension's target schema or the schema of some prerequisite extension. Since extensions often require superuser privilege to install, this can open a path to obtaining superuser privilege. To mitigate this risk, be more careful about the `search_path` used to run an installation script; disable `check_function_bodies` within the script; and fix catalog-adjustment queries used in some contrib modules to ensure they are secure. Also provide documentation to help third-party extension authors make their installation scripts secure. This is not a complete solution; extensions that depend on other extensions can still be at risk if installed carelessly. (CVE-2020-14350)

- Fix edge cases in partition pruning (Etsuro Fujita, Dmitry Dolgov)

When there are multiple partition key columns, generation of pruning tests could misbehave if some columns had no constraining `WHERE` clauses or multiple constraining clauses. This could lead to server crashes, incorrect query results, or assertion failures.

- Fix construction of parameterized BitmapAnd and BitmapOr index scans on the inside of partition-wise nestloop joins (Tom Lane)

A plan in which such a scan needed to use a value from the outside of the join would usually crash at execution.

- In logical replication walsender, fix failure to send feedback messages after sending a keepalive message (Álvaro Herrera)

This is a relatively minor problem when using built-in logical replication, because the built-in wal-receiver will send a feedback reply (which clears the incorrect state) fairly frequently anyway. But with some other replication systems, such as pglogical, it causes significant performance issues.

- Fix firing of column-specific `UPDATE` triggers in logical replication subscribers (Tom Lane)

The code neglected to account for the possibility of column numbers being different between the publisher and subscriber tables, so that if those were indeed different, wrong decisions might be made about which triggers to fire.

- Update oldest xmin and LSN values during `pg_replication_slot_advance()` (Michael Paquier)

This function previously failed to do that, possibly preventing resource cleanup (such as removal of no-longer-needed WAL segments) after manual advancement of a replication slot.

- Fix slow execution of `ts_headline()` (Tom Lane)

The phrase-search fix added in our previous set of minor releases could cause `ts_headline()` to take unreasonable amounts of time for long documents; to make matters worse, the query was not cancellable within the troublesome loop.

- Ensure the `repeat()` function can be interrupted by query cancel (Joe Conway)

- Fix `pg_current_logfile()` to not include a carriage return (`\r`) in its result on Windows (Tom Lane)
- Ensure that `pg_read_file()` and related functions read until EOF is reached (Joe Conway)

Previously, if not given a specific data length to read, these functions would stop at whatever file length was reported by `stat()`. That's unhelpful for pipes and other sorts of virtual files.

- Fix mis-handling of NaN inputs during parallel aggregation on `numeric`-type columns (Tom Lane)

If some partial aggregation workers found only NaNs while others found only non-NaNs, the results were combined incorrectly, possibly leading to the wrong overall result (i.e., not NaN when it should be).

- Reject time-of-day values greater than 24 hours (Tom Lane)

The intention of the datetime input code is to allow “24:00:00” or equivalently “23:59:60”, but no larger value. However, the range check was miscoded so that it would accept “23:59:60.*nnn*” with nonzero fractional-second *nnn*. In timestamp values this would result in wrapping into the first second of the next day. In `time` and `timetz` values, the stored value would actually be more than 24 hours, causing dump/reload failures and possibly other misbehavior.

- Undo double-quoting of index names in EXPLAIN's non-text output formats (Tom Lane, Euler Taveira)
- Fix EXPLAIN's accounting for resource usage, particularly buffer accesses, in parallel workers in a plan using Gather Merge nodes (Jehan-Guillaume de Rorthais)
- Fix timing of constraint revalidation in ALTER TABLE (David Rowley)

If ALTER TABLE needs to fully rewrite the table's contents (for example, due to change of a column's data type) and also needs to scan the table to re-validate foreign keys or CHECK constraints, it sometimes did things in the wrong order, leading to odd errors such as “could not read block 0 in file “base/nnnnn/nnnnn”: read only 0 of 8192 bytes”.

- Work around incorrect not-null markings for `pg_subscription.subslotname` and `pg_subscription_rel.srsublsn` (Tom Lane)

The bootstrap catalog data incorrectly marks these two catalog columns as always non-null. There's no easy way to correct that mistake in existing installations (though v13 and later will have the correct markings). The main place that depends on that marking being correct is JIT-enabled tuple deconstruction, so teach it to explicitly ignore the marking for these two columns. Also adjust some C code that accessed `srsublsn` without checking to see if it's null; a crash from that is improbable but perhaps not impossible.

- Cope with LATERAL references in restriction clauses attached to an un-flattened sub-SELECT in the FROM clause (Tom Lane)

This oversight could result in assertion failures or crashes at query execution.

- Avoid believing that a never-analyzed foreign table has zero tuples (Tom Lane)

This primarily affected the planner's estimate of the number of groups that would be obtained by GROUP BY.

- Remove bogus warning about “leftover placeholder tuple” in BRIN index de-summarization (Álvaro Herrera)

The case can occur legitimately after a cancelled vacuum, so warning about it is overly noisy.

- Fix selection of tablespaces for “shared fileset” temporary files (Magnus Hagander, Tom Lane)

If `temp_tablespaces` is empty or explicitly names the database's primary tablespace, such files got placed into the `pg_default` tablespace rather than the database's primary tablespace as expected.

- Fix corner-case error in masking of SP-GiST index pages during WAL consistency checking (Alexander Korotkov)

This could cause false failure reports when `wal_consistency_checking` is enabled.

- Improve error handling in the server's `buffile` module (Thomas Munro)

Fix some cases where I/O errors were indistinguishable from reaching EOF, or were not reported at all. Also add details such as block numbers and byte counts where appropriate.

- Fix conflict-checking anomalies in `SERIALIZABLE` isolation mode (Peter Geoghegan)

If a concurrently-inserted tuple was updated by a different concurrent transaction, and neither tuple version was visible to the current transaction's snapshot, serialization conflict checking could draw the wrong conclusions about whether the tuple was relevant to the results of the current transaction. This could allow a serializable transaction to commit when it should have failed with a serialization error.

- Avoid repeated marking of dead btree index entries as dead (Masahiko Sawada)

While functionally harmless, this led to useless WAL traffic when checksums are enabled or `wal_log_hints` is on.

- Avoid trouble during cleanup of a non-exclusive backup when JIT compilation has been activated during the backup (Robert Haas)
- Fix failure of some code paths to acquire the correct lock before modifying `pg_control` (Nathan Bossart, Fujii Masao)

This oversight could allow `pg_control` to be written out with an inconsistent checksum, possibly causing trouble later, including inability to restart the database if it crashed before the next `pg_control` update.

- Fix errors in `currtid()` and `currtid2()` (Michael Paquier)

These functions (which are undocumented and used only by ancient versions of the ODBC driver) contained coding errors that could result in crashes, or in confusing error messages such as “could not open file” when applied to a relation having no storage.

- Avoid calling `elog()` or `palloc()` while holding a spinlock (Michael Paquier, Tom Lane)

Logic associated with replication slots had several violations of this coding rule. While the odds of trouble are quite low, an error in the called function would lead to a stuck spinlock.

- Fix assertion in logical replication subscriber to allow use of `REPLICA IDENTITY FULL` (Euler Taveira)

This was just an incorrect assertion, so it has no impact on standard production builds.

- Report out-of-disk-space errors properly in `pg_dump` and `pg_basebackup` (Justin Pryzby, Tom Lane, Álvaro Herrera)

Some code paths could produce silly reports like “could not write file: Success”.

- Fix parallel restore of tables having both table-level privileges and per-column privileges (Tom Lane)

The table-level privilege grants have to be applied first, but a parallel restore did not reliably order them that way; this could lead to “tuple concurrently updated” errors, or to disappearance of some per-column privilege grants. The fix for this is to include dependency links between such entries in the archive file, meaning that a new dump has to be taken with a corrected `pg_dump` to ensure that the problem will not recur.

- Ensure that `pg_upgrade` runs with `vacuum_defer_cleanup_age` set to zero in the target cluster (Bruce Momjian)

If the target cluster's configuration has been modified to set `vacuum_defer_cleanup_age` to a nonzero value, that prevented freezing of the system catalogs from working properly, which caused the upgrade to fail in confusing ways. Ensure that any such setting is overridden for the duration of the upgrade.

- Fix `pg_recvlogical` to drain pending messages before exiting (Noah Misch)

Without this, the replication sender might detect a send failure and exit without making the expected final update to the replication slot's LSN position. That led to re-transmitting data after the next connection. It was also possible to miss error messages sent after the last data that `pg_recvlogical` wants to consume.

- Fix `pg_rewind`'s handling of just-deleted files in the source data directory (Justin Pryzby, Michael Paquier)

When working with an on-line source database, concurrent file deletions are possible, but `pg_rewind` would get confused if deletion happened between seeing a file's directory entry and examining it with `stat()`.

- Make `pg_test_fsync` use binary I/O mode on Windows (Michael Paquier)

Previously it wrote the test file in text mode, which is not an accurate reflection of PostgreSQL's actual usage.

- Fix `contrib/amcheck` to not complain about deleted index pages that are empty (Alexander Krotkov)

This state of affairs is normal during WAL replay.

- Fix failure to initialize local state correctly in `contrib/dblink` (Joe Conway)

With the right combination of circumstances, this could lead to `dblink_close()` issuing an unexpected remote `COMMIT`.

- Fix `contrib/pgcrypto`'s misuse of `deflate()` (Tom Lane)

The `pgp_sym_encrypt` functions could produce incorrect compressed data due to mishandling of `zlib`'s API requirements. We have no reports of this error manifesting with stock `zlib`, but it can be seen when using IBM's `zlibNX` implementation.

- Fix corner case in decompression logic in `contrib/pgcrypto`'s `pgp_sym_decrypt` functions (Kyotaro Horiguchi, Michael Paquier)

A compressed stream can validly end with an empty packet, but the decompressor failed to handle this and would complain about corrupt data.

- Use POSIX-standard `strsignal()` in place of the BSD-ish `sys_siglist[]` (Tom Lane)

This avoids build failures with very recent versions of `glibc`.

- Support building our NLS code with Microsoft Visual Studio 2015 or later (Juan José Santamaría Flecha, Davinder Singh, Amit Kapila)
- Avoid possible failure of our MSVC install script when there is a file named `configure` several levels above the source code tree (Arnold Müller)

This could confuse some logic that looked for `configure` to identify the top level of the source tree.

## E.38. Release 11.8

**Release date:** 2020-05-14

This release contains a variety of fixes from 11.7. For information about new features in major release 11, see [Section E.46](#).

### E.38.1. Migration to Version 11.8

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.6, see [Section E.40](#).

### E.38.2. Changes

- Propagate `ALTER TABLE ... SET STORAGE` to indexes (Peter Eisentraut)

Non-expression index columns have always copied the `attstorage` property of their table column at creation. Update them when `ALTER TABLE ... SET STORAGE` is done, to maintain consistency.

- Preserve the `indisclustered` setting of indexes rewritten by `ALTER TABLE` (Amit Langote, Justin Pryzby)

Previously, `ALTER TABLE` lost track of which index had been used for `CLUSTER`.

- Preserve the replica identity properties of indexes rewritten by `ALTER TABLE` (Quan Zongliang, Peter Eisentraut)
- Lock objects sooner during `DROP OWNED BY` (Álvaro Herrera)

This avoids failures in race-condition cases where another session is deleting some of the same objects.

- Fix error-case processing for `CREATE ROLE ... IN ROLE` (Andrew Gierth)

Some error cases would be reported as “unexpected node type” or the like, instead of the intended message.

- Ensure that when a partition is detached, any triggers cloned from its formerly-parent table are removed (Justin Pryzby)
- Ensure that unique indexes over partitioned tables match the equality semantics of the partitioning key (Guancheng Luo)

This would only be an issue with index opclasses that have unusual notions of equality, but it's wrong in theory, so check.

- Ensure that members of the `pg_read_all_stats` role can read all statistics views, as expected (Magnus Hagander)

The functions underlying the `pg_stat_progress_*` views had not gotten this memo.

- Repair performance regression in `information_schema.triggers` view (Tom Lane)

This patch redefines that view so that an outer `WHERE` clause constraining the table name can be pushed down into the view, allowing its calculations to be done only for triggers belonging to the table of interest rather than all triggers in the database. In a database with many triggers this would make a significant speed difference for queries of that form. Since things worked that way before v11, this is a potential performance regression. Users who find this to be a problem can fix it by replacing the view definition (or, perhaps, just deleting and reinstalling the whole `information_schema` schema).

- Fix full text search to handle NOT above a phrase search correctly (Tom Lane)

Queries such as `!(foo<->bar)` failed to find matching rows when implemented as a GiST or GIN index search.

- Fix full text search for cases where a phrase search includes an item with both prefix matching and a weight restriction (Tom Lane)
- Fix `ts_headline()` to make better headline selections when working with phrase queries (Tom Lane)

- Fix bugs in `gin_fuzzy_search_limit` processing (Adé Heyward, Tom Lane)

A small value of `gin_fuzzy_search_limit` could result in unexpected slowness due to unintentionally rescanning the same index page many times. Another code path failed to apply the intended filtering at all, possibly returning too many values.

- Allow input of type `circle` to accept the format “ $(x, y), r$ ” as the documentation says it does (David Zhang)
- Make the `get_bit()` and `set_bit()` functions cope with `bytea` strings longer than 256MB (Movead Li)

Since the bit number argument is only `int4`, it's impossible to use these functions to access bits beyond the first 256MB of a long `bytea`. We'll widen the argument to `int8` in v13, but in the meantime, allow these functions to work on the initial substring of a long `bytea`.

- Ignore file-not-found errors in `pg_ls_waldir()` and allied functions (Tom Lane)

This prevents a race condition failure if a file is removed between when we see its directory entry and when we attempt to `stat()` it.

- Avoid possibly leaking an open-file descriptor for a directory in `pg_ls_dir()`, `pg_timezone_names()`, `pg_tablespace_databases()`, and allied functions (Justin Pryzby)
- Fix polymorphic-function type resolution to correctly infer the actual type of an `anyarray` output when given only an `anyrange` input (Tom Lane)
- Avoid leakage of a hashed subplan's hash tables across multiple executions (Andreas Karlsson, Tom Lane)

This mistake could result in severe memory bloat if a query re-executed a hashed subplan enough times.

- Avoid unlikely crash when `REINDEX` is terminated by a session-shutdown signal (Tom Lane)
- Fix low-probability crash after constraint violation errors in partitioned tables (Andres Freund)
- Prevent printout of possibly-incorrect hash join table statistics in `EXPLAIN` (Konstantin Knizhnik, Tom Lane, Thomas Munro)
- Fix reporting of elapsed time for heap truncation steps in `VACUUM VERBOSE` (Tatsuhito Kasahara)
- Fix possible undercounting of deleted B-tree index pages in `VACUUM VERBOSE` output (Peter Geoghegan)
- Fix wrong bookkeeping for oldest deleted page in a B-tree index (Peter Geoghegan)

This could cause subtly wrong decisions about when `VACUUM` can skip an index cleanup scan; although it appears there may be no significant user-visible effects from that.

- Ensure that `TimelineHistoryRead` and `TimelineHistoryWrite` wait states are reported in all code paths that read or write timeline history files (Masahiro Ikeda)
- Avoid possibly showing “waiting” twice in a process's PS status (Masahiko Sawada)
- Avoid failure if autovacuum tries to access a just-dropped temporary schema (Tom Lane)

This hazard only arises if a superuser manually drops a temporary schema; which isn't normal practice, but should work.

- Avoid premature recycling of WAL segments during crash recovery (Jehan-Guillaume de Rorthais)

WAL segments that become ready to be archived during crash recovery were potentially recycled without being archived.

- Avoid scanning irrelevant timelines during archive recovery (Kyotaro Horiguchi)

This can eliminate many attempts to fetch non-existent WAL files from archive storage, which is helpful if archive access is slow.

- Remove bogus “subtransaction logged without previous top-level txn record” error check in logical decoding (Arseny Sher, Amit Kapila)

This condition is legitimately reachable in various scenarios, so remove the check.

- Ensure that a replication slot's `io_in_progress_lock` is released in failure code paths (Pavan Deolasee)

This could result in a walsender later becoming stuck waiting for the lock.

- Fix race conditions in synchronous standby management (Tom Lane)

During a change in the `synchronous_standby_names` setting, there was a window in which wrong decisions could be made about whether it is OK to release transactions that are waiting for synchronous commit. Another hazard for similarly wrong decisions existed if a walsender process exited and was immediately replaced by another.

- Ensure `nextXid` can't go backwards on a standby server (Eka Palamadai)

This race condition could allow incorrect hot standby feedback messages to be sent back to the primary server, potentially allowing `VACUUM` to run too soon on the primary.

- Add missing `SQLSTATE` values to a few error reports (Sawada Masahiko)
- Fix PL/pgSQL to reliably refuse to execute an event trigger function as a plain function (Tom Lane)
- Fix memory leak in `libpq` when using `sslmode=verify-full` (Roman Peshkurov)

Certificate verification during connection startup could leak some memory. This would become an issue if a client process opened many database connections during its lifetime.

- Fix `ecpg` to treat an argument of just “-” as meaning “read from stdin” on all platforms (Tom Lane)
- Allow tab-completion of the filename argument to `psql`'s `\gx` command (Vik Fearing)
- Add `pg_dump` support for `ALTER ... DEPENDS ON EXTENSION` (Álvaro Herrera)

`pg_dump` previously ignored dependencies added this way, causing them to be forgotten during dump/restore or `pg_upgrade`.

- Fix `pg_dump` to dump comments on RLS policy objects (Tom Lane)
- In `pg_dump`, postpone restore of event triggers till the end (Fabrízio de Royes Mello, Hamid Akhtar, Tom Lane)

This minimizes the risk that an event trigger could interfere with the restoration of other objects.

- Make `pg_verify_checksums` skip tablespace subdirectories that belong to a different PostgreSQL major version (Michael Banck, Bernd Helmle)

Such subdirectories don't really belong to our database cluster, and so must not be processed.

- Ignore temporary copies of `pg_internal.init` in `pg_verify_checksums` and related programs (Michael Paquier)
- Fix quoting of `--encoding`, `--lc-ctype` and `--lc-collate` values in `createdb` utility (Michael Paquier)
- `contrib/lo`'s `lo_manage()` function crashed if called directly rather than as a trigger (Tom Lane)
- In `contrib/ltree`, protect against overflow of `ltree` and `lquery` length fields (Nikita Glukhov)
- Work around failure in `contrib/pageinspect`'s `bt_metap()` function when an `oldest_xact` value exceeds  $2^{31}-1$  (Peter Geoghegan)

Such XIDs will now be reported as negative integers, which isn't great but it beats throwing an error. v13 will widen the output argument to `int8` to provide saner reporting.

- Fix cache reference leak in `contrib/sepysql` (Michael Luo)
- Avoid failures when dealing with Unix-style locale names on Windows (Juan José Santamaría Flecha)
- Use `pkg-config`, if available, to locate `libxml2` during configure (Hugh McMaster, Tom Lane, Peter Eisentraut)

If `pkg-config` is not present or lacks knowledge of `libxml2`, we still query `xml2-config` as before.

This change could break build processes that try to make PostgreSQL use a non-default version of `libxml2` by putting that version's `xml2-config` into the `PATH`. Instead, set `XML2_CONFIG` to point to the non-default `xml2-config`. That method will work with either older or newer PostgreSQL releases.

- In MSVC builds, cope with spaces in the path name for Python (Victor Wagner)
- In MSVC builds, fix detection of Visual Studio version to work with more language settings (Andrew Dunstan)
- In MSVC builds, use `-Wno-deprecated` with bison versions newer than 3.0, as non-Windows builds already do (Andrew Dunstan)
- Update time zone data files to tzdata release 2020a for DST law changes in Morocco and the Canadian Yukon, plus historical corrections for Shanghai.

The America/Godthab zone has been renamed to America/Nuuk to reflect current English usage; however, the old name remains available as a compatibility link.

Also, update `initdb`'s list of known Windows time zone names to include recent additions, improving the odds that it will correctly translate the system time zone setting on that platform.

## E.39. Release 11.7

**Release date:** 2020-02-13

This release contains a variety of fixes from 11.6. For information about new features in major release 11, see [Section E.46](#).

### E.39.1. Migration to Version 11.7

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.6, see [Section E.40](#).

### E.39.2. Changes

- Add missing permissions checks for `ALTER ... DEPENDS ON EXTENSION` (Álvaro Herrera)

Marking an object as dependent on an extension did not have any privilege check whatsoever. This oversight allowed any user to mark routines, triggers, materialized views, or indexes as droppable by anyone able to drop an extension. Require that the calling user own the specified object (and hence have privilege to drop it). (CVE-2020-1720)

- Ensure that row triggers on partitioned tables are correctly cloned to sub-partitions when appropriate (Álvaro Herrera)

User-defined triggers (but not triggers for foreign key or deferred unique constraints) might be missed when creating or attaching a partition.

- Fix logical replication subscriber code to execute per-column `UPDATE` triggers when appropriate (Peter Eisentraut)

- Avoid failure in logical decoding when a large transaction must be spilled into many separate temporary files (Amit Khandekar)
- Fix possible crash or data corruption when a logical replication subscriber processes a row update (Tom Lane, Tomas Vondra)

This bug caused visible problems only if the subscriber's table contained columns that were not being copied from the publisher and had pass-by-reference data types.

- Fix crash in logical replication subscriber after DDL changes on a subscribed relation (Jehan-Guil-laume de Rorthais, Vignesh C)
- Fix failure in logical replication publisher after a database crash and restart (Vignesh C)
- Ensure that the effect of `pg_replication_slot_advance()` on a physical replication slot will persist across restarts (Alexey Kondratov, Michael Paquier)
- Improve efficiency of logical replication with `REPLICA IDENTITY FULL` (Konstantin Knizhnik)

When searching for an existing tuple during an update or delete operation, return the first matching tuple not the last one.

- Ensure parallel plans are always shut down at the correct time (Kyotaro Horiguchi)

This oversight is known to result in “temporary file leak” warnings from multi-batch parallel hash joins.

- Prevent premature shutdown of a Gather or GatherMerge plan node that is underneath a Limit node (Amit Kapila)

This avoids failure if such a plan node needs to be scanned more than once, as for instance if it is on the inside of a nestloop.

- Improve efficiency of parallel hash join on CPUs with many cores (Gang Deng, Thomas Munro)
- Avoid crash in parallel `CREATE INDEX` when there are no free dynamic shared memory slots (Thomas Munro)

Fall back to a non-parallel index build, instead.

- Avoid memory leak when there are no free dynamic shared memory slots (Thomas Munro)
- Ignore the `CONCURRENTLY` option when performing an index creation, drop, or rebuild on a temporary table (Michael Paquier, Heikki Linnakangas, Andres Freund)

This avoids strange failures if the temporary table has an `ON COMMIT` action. There is no benefit in using `CONCURRENTLY` for a temporary table anyway, since other sessions cannot access the table, making the extra processing pointless.

- Fix possible failure when resetting expression indexes on temporary tables that are marked `ON COMMIT DELETE ROWS` (Tom Lane)
- Fix possible crash in BRIN index operations with `box`, `range` and `inet` data types (Heikki Linnakangas)
- Fix handling of deleted pages in GIN indexes (Alexander Korotkov)

Avoid possible deadlocks, incorrect updates of a deleted page's state, and failure to traverse through a recently-deleted page.

- Fix possible crash with a SubPlan (sub-SELECT) within a multi-row `VALUES` list (Tom Lane)
- Fix failure to insert default values for “missing” attributes during tuple conversion (Vik Fearing, Andrew Gierth)

This could result in values incorrectly reading as NULL, when they come from columns that had been added by `ALTER TABLE ADD COLUMN` with a constant default.

- Fix crash after `FileClose()` failure (Noah Misch)

This issue could only be observed with `data_sync_retry` enabled, since otherwise `FileClose()` failure would be reported as a PANIC.

- Fix unlikely crash with pass-by-reference aggregate transition states (Andres Freund, Teodor Sigaev)
- Improve error reporting in `to_date()` and `to_timestamp()` (Tom Lane, Álvaro Herrera)

Reports about incorrect month or day names in input strings could truncate the input in the middle of a multi-byte character, leading to an improperly encoded error message that could cause follow-on failures. Truncate at the next whitespace instead.

- Fix off-by-one result for `EXTRACT(ISOYEAR FROM timestamp)` for BC dates (Tom Lane)
- Avoid stack overflow in `information_schema` views when a self-referential view exists in the system catalogs (Tom Lane)

A self-referential view can't work; it will always result in infinite recursion. We handled that situation correctly when trying to execute the view, but not when inquiring whether it is automatically updatable.

- Ensure that walsender processes always show NULL for transaction start time in `pg_stat_activity` (Álvaro Herrera)

Previously, the `xact_start` column would sometimes show the process start time.

- Improve performance of hash joins with very large inner relations (Thomas Munro)
- Fix placement of “Subplans Removed” field in `EXPLAIN` output (Daniel Gustafsson, Tom Lane)

In non-text output formats, this field was emitted inside the “Plans” sub-group, resulting in syntactically invalid output. Attach it to the parent Append or MergeAppend plan node as intended. This causes the field to change position in text output format too: if there are any InitPlans attached to the same plan node, “Subplans Removed” will now appear before those.

- Allow the planner to apply potentially-leaky tests to child-table statistics, if the user can read the corresponding column of the table that's actually named in the query (Dilip Kumar, Amit Langote)

This change fixes a performance problem for partitioned tables that was created by the fix for CVE-2017-7484. That security fix disallowed applying leaky operators to statistics for columns that the current user doesn't have permission to read directly. However, it's somewhat common to grant permissions only on the parent partitioned table and not bother to do so on individual partitions. In such cases, the user can read the column via the parent, so there's no point in this security restriction; it only results in poorer planner estimates than necessary.

- Fix edge-case crashes and misestimations in selectivity calculations for the `<@` and `@>` range operators (Michael Paquier, Andrey Borodin, Tom Lane)
- Ignore system columns when applying most-common-value extended statistics (Tomas Vondra)

This prevents “negative bitmapset member not allowed” planner errors for affected queries.

- Fix BRIN index logic to support hypothetical BRIN indexes (Julien Rouhaud, Heikki Linnakangas)

Previously, if an “index adviser” extension tried to get the planner to produce a plan involving a hypothetical BRIN index, that would fail, because the BRIN cost estimation code would always try to physically access the index's metapage. Now it checks to see if the index is only hypothetical, and uses default assumptions about the index parameters if so.

- Improve error reporting for attempts to use automatic updating of views with conditional `INSTEAD` rules (Dean Rasheed)

This has never been supported, but previously the error was thrown only at execution time, so that it could be masked by planner errors.

- Prevent a composite type from being included in itself indirectly via a range type (Tom Lane, Julien Rouhaud)
- Disallow partition key expressions that return pseudo-types, such as `record` (Tom Lane)
- Fix error reporting for index expressions of prohibited types (Amit Langote)
- Fix dumping of views that contain only a `VALUES` list to handle cases where a view output column has been renamed (Tom Lane)
- Ensure that data types and collations used in `XMLTABLE` constructs are accounted for when computing dependencies of a view or rule (Tom Lane)

Previously it was possible to break a view using `XMLTABLE` by dropping a type, if the type was not otherwise referenced in the view. This fix does not correct the dependencies already recorded for existing views, only for newly-created ones.

- Prevent unwanted downcasing and truncation of `RADIUS` authentication parameters (Marcos David)

The `pg_hba.conf` parser mistakenly treated these fields as SQL identifiers, which in general they aren't.

- Transmit incoming `NOTIFY` messages to the client before sending `ReadyForQuery`, rather than after (Tom Lane)

This change ensures that, with `libpq` and other client libraries that act similarly to it, any notifications received during a transaction will be available by the time the client thinks the transaction is complete. This probably makes no difference in practical applications (which would need to cope with asynchronous notifications in any case); but it makes it easier to build test cases with reproducible behavior.

- Allow `libpq` to parse all GSS-related connection parameters even when the GSSAPI code hasn't been compiled in (Tom Lane)

This makes the behavior similar to our SSL support, where it was long ago deemed to be a good idea to always accept all the related parameters, even if some are ignored or restricted due to lack of the feature in a particular build.

- Fix incorrect handling of `%b` and `%B` format codes in `ecpg's PGTYPEtimestamp_fmt_asc()` function (Tomas Vondra)

Due to an off-by-one error, these codes would print the wrong month name, or possibly crash.

- Fix parallel `pg_dump/pg_restore` to more gracefully handle failure to create worker processes (Tom Lane)
- Prevent possible crash or lockup when attempting to terminate a parallel `pg_dump/pg_restore` run via a signal (Tom Lane)
- In `pg_upgrade`, look inside arrays and ranges while searching for non-upgradable data types in tables (Tom Lane)
- Apply more thorough syntax checking to `createuser's --connection-limit` option (Álvaro Herrera)
- Cope with changes of the specific type referenced by a PL/pgSQL composite-type variable in more cases (Ashutosh Sharma, Tom Lane)

Dropping and re-creating the composite type referenced by a PL/pgSQL variable could lead to “could not open relation with OID `NNNN`” errors.

- Avoid crash in `postgres_fdw` when trying to send a command like `UPDATE remote_tab SET (x,y) = (SELECT ...)` to the remote server (Tom Lane)
- In `contrib/dict_int`, reject `maxlen` settings less than one (Tomas Vondra)

This prevents a possible crash with silly settings for that parameter.

- Disallow NULL category values in `contrib/tablefunc`'s `crosstab()` function (Joe Conway)

This case never worked usefully, and it would crash on some platforms.

- Fix `configure`'s probe for OpenSSL's `SSL_clear_options()` function so that it works with OpenSSL versions before 1.1.0 (Michael Paquier, Daniel Gustafsson)

This problem could lead to failure to set the SSL compression option as desired, when PostgreSQL is built against an old version of OpenSSL.

- Mark some timeout and statistics-tracking GUC variables as `PGDLLIMPORT`, to allow extensions to access them on Windows (Pascal Legrand)

This applies to `idle_in_transaction_session_timeout`, `lock_timeout`, `statement_timeout`, `track_activities`, `track_counts`, and `track_functions`.

- Avoid memory leak in sanity checks for “slab” memory contexts (Tomas Vondra)

This isn't an issue for production builds, since they wouldn't ordinarily have memory context checking enabled; but the leak could be quite severe in a debug build.

- Fix multiple statistics entries reported by the LWLock statistics mechanism (Fujii Masao)

The LWLock statistics code (which is not built by default; it requires compiling with `-DLWLOCK_STATS`) could report multiple entries for the same LWLock and backend process, as a result of faulty hashtable key creation.

- Fix race condition that led to delayed delivery of interprocess signals on Windows (Amit Kapila)

This caused visible timing oddities in `NOTIFY`, and perhaps other misbehavior.

- On Windows, retry a few times after an `ERROR_ACCESS_DENIED` file access failure (Alexander Lakhin, Tom Lane)

This helps cope with cases where a file open attempt fails because the targeted file is flagged for deletion but not yet actually gone. `pg_ctl`, for example, frequently failed with such an error when probing to see if the postmaster had shut down yet.

## E.40. Release 11.6

**Release date:** 2019-11-14

This release contains a variety of fixes from 11.5. For information about new features in major release 11, see [Section E.46](#).

### E.40.1. Migration to Version 11.6

A dump/restore is not required for those running 11.X.

However, if you use the `contrib/intarray` extension with a GiST index, and you rely on indexed searches for the `<@` operator, see the entry below about that.

Also, if you are upgrading from a version earlier than 11.1, see [Section E.45](#).

### E.40.2. Changes

- Fix failure of `ALTER TABLE SET` with a custom relation option (Michael Paquier)
- Disallow changing a multiply-inherited column's type if not all parent tables were changed (Tom Lane)

Previously, this was allowed, whereupon queries on the now-out-of-sync parent would fail.

- Avoid failure if the same target table is specified twice in an `ANALYZE` command inside a transaction block (Tom Lane)
- Prevent `VACUUM` from trying to freeze an old multixact ID involving a still-running transaction (Nathan Bossart, Jeremy Schneider)

This case would lead to `VACUUM` failing until the old transaction terminates.

- `SET CONSTRAINTS ... DEFERRED` failed on partitioned tables, incorrectly complaining about lack of triggers (Álvaro Herrera)
- Fix failure when creating indexes for a partition, if the parent partitioned table contains any dropped columns (Michael Paquier)
- Fix planner's test for case-foldable characters in `ILIKE` with an ICU collation (Tom Lane)

This mistake caused the planner to treat too much of the pattern as being a fixed prefix, so that indexscans derived from an `ILIKE` clause might miss entries that they should find.

- Ensure that offset expressions in `WINDOW` clauses are processed when a query's expressions are manipulated (Andrew Gierth)

This oversight could result in assorted failures when the offsets are nontrivial expressions. One example is that a function parameter reference in such an expression would fail if the function was in-lined.

- Fix handling of whole-row variables in `WITH CHECK OPTION` expressions and row-level-security policy expressions (Andres Freund)

Previously, such usage might result in bogus errors about row type mismatches.

- Avoid postmaster failure if a parallel query requests a background worker when no postmaster child process array slots remain free (Tom Lane)
- Prevent possible double-free if a `BEFORE UPDATE` trigger returns the old tuple as-is, and it is not the last such trigger (Thomas Munro)
- Fix crash if `x = ANY (array)`, or related operations, contains a constant-null array (Tom Lane)
- Fix “unexpected relkind” error when a query tries to access a `TOAST` table (John Hsu, Michael Paquier, Tom Lane)

The error should say that permission is denied, but this case got broken during code refactoring.

- Provide a relevant error context line when an error occurs while setting GUC parameters during parallel worker startup (Thomas Munro)
- In serializable mode, ensure that row-level predicate locks are acquired on the correct version of the row (Thomas Munro, Heikki Linnakangas)

If the visible version of the row is `HOT`-updated, the lock might be taken on its now-dead predecessor, resulting in subtle failures to guarantee serialization.

- Ensure that `fsync()` is applied only to files that are opened read/write (Andres Freund, Michael Paquier)

Some code paths tried to do this after opening a file read-only, but on some platforms that causes “bad file descriptor” or similar errors.

- Allow encoding conversion to succeed on longer strings than before (Álvaro Herrera, Tom Lane)

Previously, there was a hard limit of 0.25GB on the input string, but now it will work as long as the converted output is not over 1GB.

- Avoid an unnecessary catalog lookup during heap page pruning (Thomas Munro)

It's no longer necessary to check for unlogged indexes here, and the check caused significant performance problems in some workloads. There was also at least a theoretical possibility of deadlock.

- Avoid creating unnecessarily-bulky tuple stores for window functions (Andrew Gierth)

In some cases the tuple storage would include all columns of the source table(s), not just the ones that are needed by the query.

- Fix failure to JIT-compile equality comparisons for grouping hash tables, leading to performance loss (Andres Freund)
- Allow `repalloc()` to give back space when a large chunk is reduced in size (Tom Lane)
- Ensure that temporary WAL and history files are removed at the end of archive recovery (Sawada Masahiko)
- Avoid failure in archive recovery if `recovery_min_apply_delay` is enabled (Fujii Masao)

`recovery_min_apply_delay` is not typically used in this configuration, but it should work.

- Fix logical replication failure when publisher and subscriber have different ideas about a table's replica identity columns (Jehan-Guillaume de Rorthais, Peter Eisentraut)

Declaring a column as part of the replica identity on the subscriber, when it does not exist at all on the publisher, led to “negative bitmaset member not allowed” errors.

- Avoid unwanted delay during shutdown of a logical replication walsender (Craig Ringer, Álvaro Herrera)
- Fix timeout handling in logical replication walreceiver processes (Julien Rouhaud)

Erroneous logic prevented `wal_receiver_timeout` from working in logical replication deployments.

- Correctly time-stamp replication messages for logical decoding (Jeff Janes)

This oversight resulted, for example, in `pg_stat_subscription.last_msg_send_time` usually reading as NULL.

- In logical decoding, ensure that sub-transactions are correctly accounted for when reconstructing a snapshot (Masahiko Sawada)

This error leads to assertion failures; it's unclear whether any bad effects exist in production builds.

- Fix race condition during backend exit, when the backend process has previously waited for synchronous replication to occur (Dongming Liu)
- Fix `ALTER SYSTEM` to cope with duplicate entries in `postgresql.auto.conf` (Ian Barwick)

`ALTER SYSTEM` itself will not generate such a state, but external tools that modify `postgresql.auto.conf` could do so. Duplicate entries for the target variable will now be removed, and then the new setting (if any) will be appended at the end.

- Reject include directives with empty file names in configuration files, and report include-file recursion more clearly (Ian Barwick, Tom Lane)
- Avoid logging complaints about abandoned connections when using PAM authentication (Tom Lane)

libpq-based clients will typically make two connection attempts when a password is required, since they don't prompt their user for a password until their first connection attempt fails. Therefore the server is coded not to generate useless log spam when a client closes the connection upon being asked for a password. However, the PAM authentication code hadn't gotten that memo, and would generate several messages about a phantom authentication failure.

- Fix some cases where an incomplete date specification is not detected in `time with time zone` input (Alexander Lakhin)

If a time zone with a time-varying UTC offset is specified, then a date must be as well, so that the offset can be resolved. Depending on the syntax used, this check was not enforced in some cases, allowing bogus output to be produced.

- Fix misbehavior of `bitshiftright()` (Tom Lane)

The bitstring right shift operator failed to zero out padding space that exists in the last byte of the result when the bitstring length is not a multiple of 8. While invisible to most operations, any nonzero bits there would result in unexpected comparison behavior, since bitstring comparisons don't bother to ignore the extra bits, expecting them to always be zero.

If you have inconsistent data as a result of saving the output of `bitshiftright()` in a table, it's possible to fix it with something like

```
UPDATE mytab SET bitcol = ~(~bitcol) WHERE bitcol != ~(~bitcol);
```

- Restore the ability to take type information from an `AS` clause in `json[b]_populate_record()` and `json[b]_populate_recordset()` (Tom Lane)

If the record argument is `NULL` and has no declared composite type, try to use the `AS` clause instead. This isn't recommended usage, but it used to work, and now does again.

- Avoid crash when selecting a namespace node in `XMLTABLE` (Chapman Flack)
- Fix detection of edge-case integer overflow in interval multiplication (Yuya Watari)
- Fix memory leaks in `lower()`, `upper()`, and `initcap()` functions when using ICU collations (Konstantin Knizhnik)
- Avoid crashes if `ispell` text search dictionaries contain wrong affix data (Arthur Zakirov)
- Fix incorrect compression logic for GIN posting lists (Heikki Linnakangas)

A GIN posting list item can require 7 bytes if the distance between adjacent indexed TIDs exceeds 16TB. One step in the logic was out of sync with that, and might try to write the value into a 6-byte buffer. In principle this could cause a stack overrun, but on most architectures it's likely that the next byte would be unused alignment padding, making the bug harmless. In any case the bug would be very difficult to hit.

- Fix handling of infinity, NaN, and `NULL` values in KNN-GiST (Alexander Korotkov)

The query's output order could be wrong (different from a plain sort's result) if some distances computed for non-null column values are infinity or NaN.

- Fix handling of searches for `NULL` in KNN-SP-GiST (Nikita Glukhov)
- On Windows, recognize additional spellings of the “Norwegian (Bokmål)” locale name (Tom Lane)
- Avoid compile failure if an ECPG client includes `ecpglib.h` while having `ENABLE_NLS` defined (Tom Lane)

This risk was created by a misplaced declaration: `ecpg_gettext()` should not be visible to client code.

- In `psql`, resynchronize internal state about the server after an unexpected connection loss and successful reconnection (Peter Billen, Tom Lane)

Ordinarily this is unnecessary since the state would be the same anyway. But it can matter in corner cases, such as where the connection might lead to one of several servers. This change causes `psql` to re-issue any interactive messages that it would have issued at startup, for example about whether SSL is in use.

- Avoid platform-specific null pointer dereference in `psql` (Quentin Rameau)

- In `pg_dump`, ensure stable output order for similarly-named triggers and row-level-security policy objects (Benjie Gillam)

Previously, if two triggers on different tables had the same names, they would be sorted in OID-based order, which is less desirable than sorting them by table name. Likewise for RLS policies.

- Fix `pg_dump` to work again with pre-8.3 source servers (Tom Lane)

A previous fix caused `pg_dump` to always try to query `pg_opfamily`, but that catalog doesn't exist before version 8.3.

- In `pg_restore`, treat `-f -` as meaning “output to stdout” (Álvaro Herrera)

This synchronizes `pg_restore`'s behavior with some other applications, and in particular makes pre-v12 branches act similarly to version 12's `pg_restore`, simplifying creation of dump/restore scripts that work across multiple PostgreSQL versions. Before this change, `pg_restore` interpreted such a switch as meaning “output to a file named `-`”, but few people would want that.

- Improve `pg_upgrade`'s checks for the use of a data type that has changed representation, such as `line` (Tomas Vondra)

The previous coding could be fooled by cases where the data type of interest underlies a stored column of a domain or composite type.

- Detect file read errors during `pg_basebackup` (Jeevan Chalke)
- In `pg_basebackup`, don't `fsync` output files until the end of backup (Michael Paquier)

The previous coding could result in timeout failures if `fsync` was slow.

- In `pg_rewind` with an online source cluster, disable timeouts, much as `pg_dump` does (Alexander Kukushkin)
- Fix failure in `pg_waldebug` with the `-s` option, when a continuation WAL record ends exactly at a page boundary (Andrey Lepikhov)
- In `pg_waldebug`, include the `newitemoff` field in btree page split records (Peter Geoghegan)
- In `pg_waldebug` with the `--bkp-details` option, avoid emitting extra newlines for WAL records involving full-page writes (Andres Freund)
- Fix small memory leak in `pg_waldebug` (Andres Freund)
- Fix `vacuumdb` with a high `--jobs` option to handle running out of file descriptors better (Michael Paquier)
- Fix PL/pgSQL to handle replacements of composite types better (Tom Lane)

Cover the case where a composite type is dropped entirely, and then a new type of the same name is created, between executions of a PL/pgSQL function. Variables of the composite type will now update to match the new definition.

- Fix `contrib/amcheck` to skip unlogged indexes during hot standby (Andrey Borodin, Peter Geoghegan)

An unlogged index won't necessarily contain valid data in this context, so don't try to check it.

- Fix `contrib/intarray`'s GiST opclasses to not fail for empty arrays with `<@` (Tom Lane)

A clause like `array_column <@ constant_array` is considered indexable, but the index search may not find empty array values; of course, such entries should trivially match the search.

The only practical back-patchable fix for this requires making `<@` index searches scan the whole index, which is what this patch does. This is unfortunate: it means that the query performance is likely worse than a plain sequential scan would be.

Applications whose performance is adversely impacted by this change have a couple of options. They could switch to a GIN index, which doesn't have this bug, or they could replace `array_column <@ constant_array` with `array_column <@ constant_array AND array_column && constant_array`. That will provide about the same performance as before, and it will find all non-empty subsets of the given constant array, which is all that could reliably be expected of the query before.

- Fix configure's test for presence of libperl so that it works on recent Red Hat releases (Tom Lane)

Previously, it could fail if the user sets `CFLAGS` to `-O0`.

- Ensure correct code generation for spinlocks on PowerPC (Noah Misch)

The previous spinlock coding allowed the compiler to select register zero for use with an assembly instruction that does not accept that register, causing a build failure. We have seen only one long-ago report that matches this bug, but it could cause problems for people trying to build modified PostgreSQL code or use atypical compiler options.

- On PowerPC, avoid depending on the xlc compiler's `__fetch_and_add()` function (Noah Misch)

xlc 13 and newer interpret this function in a way incompatible with our usage, resulting in an unusable build of PostgreSQL. Fix by using custom assembly code instead.

- On AIX, don't use the compiler option `-qsrcmsg` (Noah Misch)

This avoids an internal compiler error with xlc v16.1.0, with little consequence other than changing the format of compiler error messages.

- Fix MSVC build process to cope with spaces in the file path of OpenSSL (Andrew Dunstan)
- Update time zone data files to tzdata release 2019c for DST law changes in Fiji and Norfolk Island, plus historical corrections for Alberta, Austria, Belgium, British Columbia, Cambodia, Hong Kong, Indiana (Perry County), Kaliningrad, Kentucky, Michigan, Norfolk Island, South Korea, and Turkey.

## E.41. Release 11.5

**Release date:** 2019-08-08

This release contains a variety of fixes from 11.4. For information about new features in major release 11, see [Section E.46](#).

### E.41.1. Migration to Version 11.5

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.1, see [Section E.45](#).

### E.41.2. Changes

- Require schema qualification to cast to a temporary type when using functional cast syntax (Noah Misch)

We have long required invocations of temporary functions to explicitly specify the temporary schema, that is `pg_temp.func_name(args)`. Require this as well for casting to temporary types using functional notation, for example `pg_temp.type_name(arg)`. Otherwise it's possible to capture a function call using a temporary object, allowing privilege escalation in much the same ways that we blocked in CVE-2007-2138. (CVE-2019-10208)

- Fix execution of hashed subplans that require cross-type comparison (Tom Lane, Andreas Seltenreich)

Hashed subplans used the outer query's original comparison operator to compare entries of the hash table. This is the wrong thing if that operator is cross-type, since all the hash table entries will

be of the subquery's output type. For the set of hashable cross-type operators in core PostgreSQL, this mistake seems nearly harmless on 64-bit machines, but it can result in crashes or perhaps unauthorized disclosure of server memory on 32-bit machines. Extensions might provide hashable cross-type operators that create larger risks. (CVE-2019-10209)

- Fix failure of `ALTER TABLE ... ALTER COLUMN TYPE` when altering multiple columns' types in one command (Tom Lane)

This fixes a regression introduced in the most recent minor releases: indexes using the altered columns were not processed correctly, leading to strange failures during `ALTER TABLE`.

- Prevent dropping a partitioned table's trigger if there are pending trigger events in child partitions (Álvaro Herrera)

This notably applies to foreign key constraints, since those are implemented by triggers.

- Include user-specified trigger arguments when copying a trigger definition from a partitioned table to one of its partitions (Patrick McHardy)
- Install dependencies to prevent dropping partition key columns (Tom Lane)

`ALTER TABLE ... DROP COLUMN` will refuse to drop a column that is a partition key column. However, indirect drops (such as a cascade from dropping a key column's data type) had no such check, allowing the deletion of a key column. This resulted in a badly broken partitioned table that could neither be accessed nor dropped.

This fix adds `pg_depend` entries that enforce that the whole partitioned table, not just the key column, will be dropped if a cascaded drop forces removal of the key column. However, such entries will only be created when a partitioned table is created; so this fix does not remove the risk for pre-existing partitioned tables. The issue can only arise for partition key columns of non-built-in data types, so it seems not to be a hazard for most users.

- Ensure that column numbers are correctly mapped between a partitioned table and its default partition (Amit Langote)

Some operations misbehaved if the mapping wasn't exactly one-to-one, for example if there were dropped columns in one table and not the other.

- Ignore partitions that are foreign tables when creating indexes on partitioned tables (Álvaro Herrera)

Previously an error was thrown on encountering a foreign-table partition, but that's unhelpful and doesn't protect against any actual problem.

- Prune a partitioned table's default partition (that is, avoid uselessly scanning it) in more cases (Yuzuko Hosoya)
- Fix possible failure to prune partitions when there are multiple partition key columns of `boolean` type (David Rowley)
- Don't optimize away `GROUP BY` columns when the table involved is an inheritance parent (David Rowley)

Normally, if a table's primary key column(s) are included in `GROUP BY`, it's safe to drop any other grouping columns, since the primary key columns are enough to make the groups unique. This rule does not work if the query is also reading inheritance child tables, though; the parent's uniqueness does not extend to the children.

- Avoid incorrect use of parallel hash join for semi-join queries (Thomas Munro)

This error resulted in duplicate result rows from some `EXISTS` queries.

- Avoid using unnecessary sort steps for some queries with `GROUPING SETS` (Andrew Gierth, Richard Guo)

- Fix possible failure of planner's index endpoint probes (Tom Lane)

When using a recently-created index to determine the minimum or maximum value of a column, the planner could select a recently-dead tuple that does not actually contain the endpoint value. In the worst case the tuple might contain a null, resulting in a visible error “found unexpected null value in index”; more likely we would just end up using the wrong value, degrading the quality of planning estimates.

- Fix failure to access trigger transition tables during `EvalPlanQual` rechecks (Alex Aktsipetrov)

Triggers that rely on transition tables sometimes failed in the presence of concurrent updates.

- Fix mishandling of multi-column foreign keys when rebuilding a foreign key constraint (Tom Lane)

`ALTER TABLE` could make an incorrect decision about whether revalidation of a foreign key is necessary, if not all columns of the key are of the same type. It seems likely that the error would always have been in the conservative direction, that is revalidating unnecessarily.

- Don't build extended statistics for inheritance trees (Tomas Vondra)

This avoids a “tuple already updated by self” error during `ANALYZE`.

- Avoid spurious deadlock errors when upgrading a tuple lock (Oleksii Kliukin)

When two or more transactions are waiting for a transaction T1 to release a tuple-level lock, and T1 upgrades its lock to a higher level, a spurious deadlock among the waiting transactions could be reported when T1 finishes.

- Fix failure to resolve deadlocks involving multiple parallel worker processes (Rui Hai Jiang)

It is not clear whether this bug is reachable with non-artificial queries, but if it did happen, the queries involved in an otherwise-resolvable deadlock would block until canceled.

- Prevent incorrect canonicalization of date ranges with `infinity` endpoints (Laurenz Albe)

It's incorrect to try to convert an open range to a closed one or vice versa by incrementing or decrementing the endpoint value, if the endpoint is infinite; so leave the range alone in such cases.

- Fix loss of fractional digits when converting very large `money` values to `numeric` (Tom Lane)
- Fix printing of `BTREE_META_CLEANUP` WAL records (Michael Paquier)
- Prevent assertion failures due to mishandling of version-2 btree metapages (Peter Geoghegan)
- Fix spinlock assembly code for MIPS CPUs so that it works on MIPS r6 (YunQiang Su)
- Ensure that a record or row value returned from a PL/pgSQL function is marked with the function's declared composite type (Tom Lane)

This avoids problems if the result is stored directly into a table.

- Make `libpq` ignore carriage return (`\r`) in connection service files (Tom Lane, Michael Paquier)

In some corner cases, service files containing Windows-style newlines could be mis-parsed, resulting in connection failures.

- In `psql`, avoid offering incorrect tab completion options after `SET variable =` (Tom Lane)
- Fix a small memory leak in `psql`'s `\d` command (Tom Lane)
- Fix `pg_dump` to ensure that custom operator classes are dumped in the right order (Tom Lane)

If a user-defined opclass is the subtype opclass of a user-defined range type, related objects were dumped in the wrong order, producing an unrestorable dump. (The underlying failure to handle opclass dependencies might manifest in other cases too, but this is the only known case.)

- Fix possible lockup in `pgbench` when using `-R` option (Fabien Coelho)

- Improve reliability of `contrib/amcheck`'s index verification (Peter Geoghegan)
- Fix handling of Perl `undef` values in `contrib/jsonb_plperl` (Ivan Panchenko)
- Fix `contrib/passwordcheck` to coexist with other users of `check_password_hook` (Michael Paquier)
- Fix `contrib/sepgsql` tests to work under recent SELinux releases (Mike Palmiotto)
- Improve stability of `src/test/kerberos` and `src/test/ldap` regression tests (Thomas Munro, Tom Lane)
- Improve stability of `src/test/recovery` regression tests (Michael Paquier)
- Reduce stderr output from `pg_upgrade`'s test script (Tom Lane)
- Fix `pgbench` regression tests to work on Windows (Fabien Coelho)
- Fix TAP tests to work with `msys Perl`, in cases where the build directory is on a non-root `msys` mount point (Noah Misch)
- Support building Postgres with Microsoft Visual Studio 2019 (Haribabu Kommi)
- In Visual Studio builds, honor `WindowsSDKVersion` environment variable, if that's set (Peifeng Qiu)

This fixes build failures in some configurations.

- Support OpenSSL 1.1.0 and newer in Visual Studio builds (Juan José Santamaría Flecha, Michael Paquier)
- Allow make options to be passed down to `gmake` when non-GNU make is invoked at the top level (Thomas Munro)
- Avoid choosing `localtime` or `posixrules` as `TimeZone` during `initdb` (Tom Lane)

In some cases `initdb` would choose one of these artificial zone names over the “real” zone name. Prefer any other match to the C library's `timezone` behavior over these two.

- Adjust `pg_timezone_names` view to show the `Factory` time zone if and only if it has a short abbreviation (Tom Lane)

Historically, IANA set up this artificial zone with an “abbreviation” like `Local time zone must be set--see zic manual page`. Modern versions of the `tzdb` database show `-00` instead, but some platforms alter the data to show one or another of the historical phrases. Show this zone only if it uses the modern abbreviation.

- Sync our copy of the `timezone` library with IANA `tzcode` release 2019b (Tom Lane)

This adds support for `zic`'s new `-b slim` option to reduce the size of the installed zone files. We are not currently using that, but may enable it in future.

- Update time zone data files to `tzdata` release 2019b for DST law changes in Brazil, plus historical corrections for Hong Kong, Italy, and Palestine.

## E.42. Release 11.4

**Release date:** 2019-06-20

This release contains a variety of fixes from 11.3. For information about new features in major release 11, see [Section E.46](#).

### E.42.1. Migration to Version 11.4

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.1, see [Section E.45](#).

## E.42.2. Changes

- Fix buffer-overflow hazards in SCRAM verifier parsing (Jonathan Katz, Heikki Linnakangas, Michael Paquier)

Any authenticated user could cause a stack-based buffer overflow by changing their own password to a purpose-crafted value. In addition to the ability to crash the PostgreSQL server, this could suffice for executing arbitrary code as the PostgreSQL operating system account.

A similar overflow hazard existed in libpq, which could allow a rogue server to crash a client or perhaps execute arbitrary code as the client's operating system account.

The PostgreSQL Project thanks Alexander Lakhin for reporting this problem. (CVE-2019-10164)

- Fix assorted errors in run-time partition pruning logic (Tom Lane, Amit Langote, David Rowley)

These mistakes could lead to wrong answers in queries on partitioned tables, if the comparison value used for pruning is dynamically determined, or if multiple range-partitioned columns are involved in pruning decisions, or if stable (not immutable) comparison operators are involved.

- Fix possible crash while trying to copy trigger definitions to a new partition (Tom Lane)
- Fix failure of `ALTER TABLE ... ALTER COLUMN TYPE` when the table has a partial exclusion constraint (Tom Lane)
- Fix failure of `COMMENT` command for comments on domain constraints (Daniel Gustafsson, Michael Paquier)
- Prevent possible memory clobber when there are duplicate columns in a hash aggregate's hash key list (Andrew Gierth)
- Fix incorrect argument null-ness checking during partial aggregation of aggregates with zero or multiple arguments (David Rowley, Kyotaro Horiguchi, Andres Freund)
- Fix faulty generation of merge-append plans (Tom Lane)

This mistake could lead to “could not find pathkey item to sort” errors.

- Fix incorrect printing of queries with duplicate join names (Philip Dubé)

This oversight caused a dump/restore failure for views containing such queries.

- Fix conversion of JSON string literals to JSON-type output columns in `json_to_record()` and `json_populate_record()` (Tom Lane)

Such cases should produce the literal as a standalone JSON value, but the code misbehaved if the literal contained any characters requiring escaping.

- Fix misoptimization of `{1,1}` quantifiers in regular expressions (Tom Lane)

Such quantifiers were treated as no-ops and optimized away; but the documentation specifies that they impose greediness, or non-greediness in the case of the non-greedy variant `{1,1}?`, on the subexpression they're attached to, and this did not happen. The misbehavior occurred only if the subexpression contained capturing parentheses or a back-reference.

- Avoid writing an invalid empty btree index page in the unlikely case that a failure occurs while processing INCLUDED columns during a page split (Peter Geoghegan)

The invalid page would not affect normal index operations, but it might cause failures in subsequent VACUUMs. If that has happened to one of your indexes, recover by reindexing the index.

- Avoid possible failures while initializing a new process's `pg_stat_activity` data (Tom Lane)

Certain operations that could fail, such as converting strings extracted from an SSL certificate into the database encoding, were being performed inside a critical section. Failure there would result in database-wide lockup due to violating the access protocol for shared `pg_stat_activity` data.

- Fix race condition in check to see whether a pre-existing shared memory segment is still in use by a conflicting postmaster (Tom Lane)
- Fix unsafe coding in walreceiver's signal handler (Tom Lane)

This avoids rare problems in which the walreceiver process would crash or deadlock when commanded to shut down.

- Avoid attempting to do database accesses for parameter checking in processes that are not connected to a specific database (Vignesh C, Andres Freund)

This error could result in failures like “cannot read pg\_class without having selected a database”.

- Avoid possible hang in libpq if using SSL and OpenSSL's pending-data buffer contains an exact multiple of 256 bytes (David Binderman)
- Improve initdb's handling of multiple equivalent names for the system time zone (Tom Lane, Andrew Gieth)

Make initdb examine the `/etc/localtime` symbolic link, if that exists, to break ties between equivalent names for the system time zone. This makes initdb more likely to select the time zone name that the user would expect when multiple identical time zones exist. It will not change the behavior if `/etc/localtime` is not a symlink to a zone data file, nor if the time zone is determined from the `TZ` environment variable.

Separately, prefer UTC over other spellings of that time zone, when neither `TZ` nor `/etc/localtime` provide a hint. This fixes an annoyance introduced by tzdata 2019a's change to make the UCT and UTC zone names equivalent: initdb was then preferring UCT, which almost nobody wants.

- Fix ordering of GRANT commands emitted by pg\_dump and pg\_dumpall for databases and tablespaces (Nathan Bossart, Michael Paquier)

If cascading grants had been issued, restore might fail due to the GRANT commands being given in an order that didn't respect their interdependencies.

- Make pg\_dump recreate table partitions using CREATE TABLE then ATTACH PARTITION, rather than including PARTITION OF in the creation command (Álvaro Herrera, David Rowley)

This avoids problems with the partition's column order possibly being changed to match the parent's. Also, a partition is now restorable from the dump (as a standalone table) even if its parent table isn't restored; the ATTACH will fail, but that can just be ignored.

- Fix misleading error reports from reindexdb (Julien Rouhaud)
- Ensure that vacuumdb returns correct status if an error occurs while using parallel jobs (Julien Rouhaud)
- Fix contrib/auto\_explain to not cause problems in parallel queries (Tom Lane)

Previously, a parallel worker might try to log its query even if the parent query were not being logged by auto\_explain. This would work sometimes, but it's confusing, and in some cases it resulted in failures like “could not find key N in shm TOC”.

Also, fix an off-by-one error that resulted in not necessarily logging every query even when the sampling rate is set to 1.0.

- In contrib/postgres\_fdw, account for possible data modifications by local BEFORE ROW UPDATE triggers (Shohei Mochizuki)

If a trigger modified a column that was otherwise not changed by the UPDATE, the new value was not transmitted to the remote server.

- On Windows, avoid failure when the database encoding is set to SQL\_ASCII and we attempt to log a non-ASCII string (Noah Misch)

The code had been assuming that such strings must be in UTF-8, and would throw an error if they didn't appear to be validly encoded. Now, just transmit the untranslated bytes to the log.

- Make PL/pgSQL's header files C++-safe (George Tarasov)

## E.43. Release 11.3

**Release date:** 2019-05-09

This release contains a variety of fixes from 11.2. For information about new features in major release 11, see [Section E.46](#).

### E.43.1. Migration to Version 11.3

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.1, see [Section E.45](#).

### E.43.2. Changes

- Prevent row-level security policies from being bypassed via selectivity estimators (Dean Rasheed)

Some of the planner's selectivity estimators apply user-defined operators to values found in `pg_statistic` (e.g., most-common values). A leaky operator therefore can disclose some of the entries in a data column, even if the calling user lacks permission to read that column. In CVE-2017-7484 we added restrictions to forestall that, but we failed to consider the effects of row-level security. A user who has SQL permission to read a column, but who is forbidden to see certain rows due to RLS policy, might still learn something about those rows' contents via a leaky operator. This patch further tightens the rules, allowing leaky operators to be applied to statistics data only when there is no relevant RLS policy. (CVE-2019-10130)

- Avoid access to already-freed memory during partition routing error reports (Michael Paquier)

This mistake could lead to a crash, and in principle it might be possible to use it to disclose server memory contents. (CVE-2019-10129)

- Avoid catalog corruption when an `ALTER TABLE` on a partitioned table finds that a partitioned index is reusable (Amit Langote, Tom Lane)

This occurs, for example, when `ALTER COLUMN TYPE` finds that no physical table rewrite is required.

- Avoid catalog corruption when a temporary table with `ON COMMIT DROP` and an identity column is created in a single-statement transaction (Peter Eisentraut)

This hazard was overlooked because the case is not actually useful, since the temporary table would be dropped immediately after creation.

- Fix failure in `ALTER INDEX ... ATTACH PARTITION` if the partitioned table contains more dropped columns than its partition does (Álvaro Herrera)
- Fix failure to attach a partition's existing index to a newly-created partitioned index in some cases (Amit Langote, Álvaro Herrera)

This would lead to errors such as “index ... not found in partition” in subsequent DDL that uses the partitioned index.

- Avoid crash when an EPQ recheck is performed for a partitioned query result relation (Amit Langote)

This occurs when using `READ COMMITTED` isolation level and another session has concurrently updated some of the target row(s).

- Fix tuple routing in multi-level partitioned tables that have dropped attributes (Amit Langote, Michael Paquier)
- Fix failure when the slow path of foreign key constraint initial validation is applied to partitioned tables (Hadi Moshayedi, Tom Lane, Andres Freund)

This didn't manifest except in the uncommon cases where the fast path can't be used (such as permissions problems).

- Fix behavior for an `UPDATE` or `DELETE` on an inheritance tree or partitioned table in which every table can be excluded (Amit Langote, Tom Lane)

In such cases, the query did not report the correct set of output columns when a `RETURNING` clause was present, and if there were any statement-level triggers that should be fired, it didn't fire them.

- When accessing a partition directly, and `constraint_exclusion` is set to `on`, use the partition's partition constraint as well as any `CHECK` constraints for exclusion checking (Amit Langote, Tom Lane)

This change restores the behavior to what it was in v10.

- Avoid server crash when an error occurs while trying to persist a cursor query across a transaction commit (Tom Lane)

If a procedure attempts to commit while it has an open explicit or implicit cursor (for example, a PL/pgSQL `FOR`-loop query), the cursor must be executed to completion and its results saved before the transaction commit can be performed. An error occurring during such execution led to a crash.

- Avoid throwing incorrect errors for updates of temporary tables and unlogged tables when a `FOR ALL TABLES` publication exists (Peter Eisentraut)

Such tables should be ignored for publication purposes, but some parts of the code failed to do so.

- Fix handling of explicit `DEFAULT` items in an `INSERT ... VALUES` command with multiple `VALUES` rows, if the target relation is an updatable view (Amit Langote, Dean Rasheed)

When the updatable view has no default for the column but its underlying table has one, a single-row `INSERT ... VALUES` will use the underlying table's default. In the multi-row case, however, `NULL` was always used. Correct it to act like the single-row case.

- Fix `CREATE VIEW` to allow zero-column views (Ashutosh Sharma)

We should allow this for consistency with allowing zero-column tables. Since a table can be converted to a view, zero-column views could be created even with the restriction in place, leading to dump/reload failures.

- Add missing support for `CREATE TABLE IF NOT EXISTS ... AS EXECUTE ...` (Andreas Karlsson)

The combination of `IF NOT EXISTS` and `EXECUTE` should work, but the grammar omitted it.

- Ensure that sub-`SELECT`s appearing in row-level-security policy expressions are executed with the correct user's permissions (Dean Rasheed)

Previously, if the table having the RLS policy was accessed via a view, such checks might be executed as the user calling the view, not as the view owner as they should be.

- Accept XML documents as valid values of type `xml` when `xmloption` is set to `content`, as required by SQL:2006 and later (Chapman Flack)

Previously PostgreSQL followed the SQL:2003 definition, which doesn't allow this. But that creates a serious problem for dump/restore: there is no setting of `xmloption` that will accept all valid XML data. Hence, switch to the 2006 definition.

`pg_dump` is also modified to emit `SET xmloption = content` while restoring data, ensuring that dump/restore works even if the prevailing setting is `document`.

- Improve server's startup-time checks for whether a pre-existing shared memory segment is still in use (Noah Misch)

The postmaster is now more likely to detect that there are still active processes from a previous postmaster incarnation, even if the `postmaster.pid` file has been removed.

- Avoid possible division-by-zero in btree index vacuum logic (Piotr Stefaniak, Alexander Korotkov)

This could lead to incorrect decisions about whether index cleanup is needed.

- Avoid counting parallel workers' transactions as separate transactions (Haribabu Kommi)
- Fix incompatibility of GIN-index WAL records (Alexander Korotkov)

A fix applied in February's minor releases was not sufficiently careful about backwards compatibility, leading to problems if a standby server of that vintage reads GIN page-deletion WAL records generated by a primary server of a previous minor release.

- Fix possible crash while executing a `SHOW` command in a replication connection (Michael Paquier)
- Avoid server memory leak when fetching rows from a portal one at a time (Tom Lane)
- Avoid memory leak when a partition's relation cache entry is rebuilt (Amit Langote, Tom Lane)
- Tolerate `EINVAL` and `ENOSYS` error results, where appropriate, for `fsync` and `sync_file_range` calls (Thomas Munro, James Sewell)

The previous change to panic on file synchronization failures turns out to have been excessively paranoid for certain cases where a failure is predictable and essentially means “operation not supported”.

- Report correct relation name in autovacuum's `pg_stat_activity` display during BRIN summarize operations (Álvaro Herrera)
- Avoid crash when trying to plan a partition-wise join when GEQO is active (Tom Lane)
- Fix “failed to build any *N*-way joins” planner failures with lateral references leading out of `FULL` outer joins (Tom Lane)
- Fix misplanning of queries in which a set-returning function is applied to a relation that is provably empty (Tom Lane, Julien Rouhaud)

In v10, this oversight only led to slightly inefficient plans, but in v11 it could cause “set-valued function called in context that cannot accept a set” errors.

- Check the appropriate user's permissions when enforcing rules about letting a leaky operator see `pg_statistic` data (Dean Rasheed)

When an underlying table is being accessed via a view, consider the privileges of the view owner while deciding whether leaky operators may be applied to the table's statistics data, rather than the privileges of the user making the query. This makes the planner's rules about what data is visible match up with the executor's, avoiding unnecessarily-poor plans.

- Fix planner's parallel-safety assessment for grouped queries (Etsuro Fujita)

Previously, target-list evaluation work that could have been parallelized might not be.

- Fix mishandling of “included” index columns in planner's unique-index logic (Tom Lane)

This could result in failing to recognize that a unique index with included columns proves uniqueness of a query result, leading to a poor plan.

- Fix incorrect strictness check for array coercion expressions (Tom Lane)

This might allow, for example, incorrect inlining of a strict SQL function, leading to non-enforcement of the strictness condition.

- Speed up planning when there are many equality conditions and many potentially-relevant foreign key constraints (David Rowley)
- Avoid  $O(N^2)$  performance issue when rolling back a transaction that created many tables (Tomas Vondra)
- Fix corner-case server crashes in dynamic shared memory allocation (Thomas Munro, Robert Haas)
- Fix race conditions in management of dynamic shared memory (Thomas Munro)

These could lead to “dsa\_area could not attach to segment” or “cannot unpin a segment that is not pinned” errors.

- Fix race condition in which a hot-standby postmaster could fail to shut down after receiving a smart-shutdown request (Tom Lane)
- Fix possible crash when `pg_identify_object_as_address()` is given invalid input (Álvaro Herrera)
- Fix possible “could not access status of transaction” failures in `txid_status()` (Thomas Munro)
- Fix authentication failure when attempting to use SCRAM authentication with mixed OpenSSL library versions (Michael Paquier, Peter Eisentraut)

If libpq is using OpenSSL 1.0.1 or older while the server is using OpenSSL 1.0.2 or newer, the negotiation of which SASL mechanism to use went wrong, leading to a confusing “channel binding not supported by this build” error message.

- Tighten validation of encoded SCRAM-SHA-256 and MD5 passwords (Jonathan Katz)

A password string that had the right initial characters could be mistaken for one that is correctly hashed into SCRAM-SHA-256 or MD5 format. The password would be accepted but would be unusable later.

- Fix handling of `lc_time` settings that imply an encoding different from the database's encoding (Juan José Santamaría Flecha, Tom Lane)

Localized month or day names that include non-ASCII characters previously caused unexpected errors or wrong output in such locales.

- Create the `current_logfiles` file with the same permissions as other files in the server's data directory (Haribabu Kommi)

Previously it used the permissions specified by `log_file_mode`, but that can cause problems for backup utilities.

- Fix incorrect `operator_precedence_warning` checks involving unary minus operators (Rikard Falkeborn)
- Disallow NaN as a value for floating-point server parameters (Tom Lane)
- Rearrange `REINDEX` processing to avoid assertion failures when reindexing individual indexes of `pg_class` (Andres Freund, Tom Lane)
- Fix planner assertion failure for parameterized dummy paths (Tom Lane)
- Insert correct test function in the result of `SnapBuildInitialSnapshot()` (Antonin Houska)

No core code cares about this, but some extensions do.

- Fix intermittent “could not reattach to shared memory” session startup failures on Windows (Noah Misch)

A previously unrecognized source of these failures is creation of thread stacks for a process's default thread pool. Arrange for such stacks to be allocated in a different memory region.

- Fix error detection in directory scanning on Windows (Konstantin Knizhnik)

Errors, such as lack of permissions to read the directory, were not detected or reported correctly; instead the code silently acted as though the directory were empty.

- Fix grammar problems in `ecpg` (Tom Lane)

A missing semicolon led to mistranslation of `SET variable = DEFAULT` (but not `SET variable TO DEFAULT`) in `ecpg` programs, producing syntactically invalid output that the server would reject. Additionally, in a `DROP TYPE` or `DROP DOMAIN` command that listed multiple type names, only the first type name was actually processed.

- Sync `ecpg`'s syntax for `CREATE TABLE AS` with the server's (Daisuke Higuchi)
- Fix possible buffer overruns in `ecpg`'s processing of include filenames (Liu Huailing, Fei Wu)
- Fix `pg_rewind` failures due to failure to remove some transient files in the target data directory (Michael Paquier)
- Make `pg_verify_checksums` verify that the data directory it's pointed at is of the right PostgreSQL version (Michael Paquier)
- Avoid crash in `contrib/postgres_fdw` when a query using remote grouping or aggregation has a `SELECT`-list item that is an uncorrelated sub-select, outer reference, or parameter symbol (Tom Lane)
- Change `contrib/postgres_fdw` to report an error when a remote partition chosen to insert a routed row into is also an `UPDATE` subplan target that will be updated later in the same command (Amit Langote, Etsuro Fujita)

Previously, such situations led to server crashes or incorrect results of the `UPDATE`. Allowing such cases to work correctly is a matter for future work.

- In `contrib/pg_prewarm`, avoid indefinitely respawning background worker processes if prewarming fails for some reason (Mithun Cy)
- Avoid crash in `contrib/vacuumlo` if an `lo_unlink()` call failed (Tom Lane)
- Sync our copy of the timezone library with IANA tzcode release 2019a (Tom Lane)

This corrects a small bug in `zic` that caused it to output an incorrect year-2440 transition in the `Africa/Casablanca` zone, and adds support for `zic`'s new `-r` option.

- Update time zone data files to `tzdata` release 2019a for DST law changes in Palestine and Metlakatla, plus historical corrections for Israel.

`Etc/UCT` is now a backward-compatibility link to `Etc/UTC`, instead of being a separate zone that generates the abbreviation `UCT`, which nowadays is typically a typo. PostgreSQL will still accept `UCT` as an input zone abbreviation, but it won't output it.

## E.44. Release 11.2

**Release date:** 2019-02-14

This release contains a variety of fixes from 11.1. For information about new features in major release 11, see [Section E.46](#).

### E.44.1. Migration to Version 11.2

A dump/restore is not required for those running 11.X.

However, if you are upgrading from a version earlier than 11.1, see [Section E.45](#).

### E.44.2. Changes

- By default, panic instead of retrying after `fsync()` failure, to avoid possible data corruption (Craig Ringer, Thomas Munro)

Some popular operating systems discard kernel data buffers when unable to write them out, reporting this as `fsync()` failure. If we reissue the `fsync()` request it will succeed, but in fact the data has been lost, so continuing risks database corruption. By raising a panic condition instead, we can replay from WAL, which may contain the only remaining copy of the data in such a situation. While this is surely ugly and inefficient, there are few alternatives, and fortunately the case happens very rarely.

A new server parameter `data_sync_retry` has been added to control this; if you are certain that your kernel does not discard dirty data buffers in such scenarios, you can set `data_sync_retry` to `on` to restore the old behavior.

- Include each major release branch's release notes in the documentation for only that branch, rather than that branch and all later ones (Tom Lane)

The duplication induced by the previous policy was getting out of hand. Our plan is to provide a full archive of release notes on the project's web site, but not duplicate it within each release.

- Fix handling of unique indexes with `INCLUDE` columns on partitioned tables (Álvaro Herrera)

The uniqueness condition was not checked properly in such cases.

- Ensure that `NOT NULL` constraints of a partitioned table are honored within its partitions (Álvaro Herrera, Amit Langote)
- Update catalog state correctly for partition table constraints when detaching their partition (Amit Langote, Álvaro Herrera)

Previously, the `pg_constraint.conislocal` field for such a constraint might improperly be left as `false`, rendering it undroppable. A dump/restore or `pg_upgrade` would cure the problem, but if necessary, the catalog field can be adjusted manually.

- Create or delete foreign key enforcement triggers correctly when attaching or detaching a partition in a partitioned table that has a foreign-key constraint (Amit Langote, Álvaro Herrera)
- Avoid useless creation of duplicate foreign key constraints in partitioned tables (Álvaro Herrera)
- When an index is created on a partitioned table using `ONLY`, and there are no partitions yet, mark it valid immediately (Álvaro Herrera)

Otherwise there is no way to make it become valid.

- Use a safe table lock level when detaching a partition (Álvaro Herrera)

The previous locking level was too weak and might allow concurrent DDL on the table, with bad results.

- Fix problems with applying `ON COMMIT DROP` and `ON COMMIT DELETE ROWS` to partitioned tables and tables with inheritance children (Michael Paquier)
- Disallow `COPY FREEZE` on partitioned tables (David Rowley)

This should eventually be made to work, but it may require a patch that's too complicated to risk back-patching.

- Fix possible index corruption when the indexed column has a “fast default” (that is, it was added by `ALTER TABLE ADD COLUMN` with a constant non-NULL default value specified, after the table already contained some rows) (Andres Freund)
- Correctly adjust “fast default” values during `ALTER TABLE ... ALTER COLUMN TYPE` (Andrew Dunstan)
- Avoid possible deadlock when acquiring multiple buffer locks (Nishant Fnu)
- Avoid deadlock between GIN vacuuming and concurrent index insertions (Alexander Korotkov, Andrey Borodin, Peter Geoghegan)

This change partially reverts a performance improvement, introduced in version 10.0, that attempted to reduce the number of index pages locked during deletion of a GIN posting tree page. That's now been found to lead to deadlocks, so we've removed it pending closer analysis.

- Avoid deadlock between hot-standby queries and replay of GIN index page deletion (Alexander Korotkov)
- Fix possible crashes in logical replication when index expressions or predicates are in use (Peter Eisentraut)
- Avoid useless and expensive logical decoding of TOAST data during a table rewrite (Tomas Vondra)
- Fix logic for stopping a subset of WAL senders when synchronous replication is enabled (Paul Guo, Michael Paquier)
- Avoid possibly writing an incorrect replica identity field in a tuple deletion WAL record (Stas Kelvich)
- Prevent incorrect use of WAL-skipping optimization during `COPY` to a view or foreign table (Amit Langote, Michael Paquier)
- Make the archiver prioritize WAL history files over WAL data files while choosing which file to archive next (David Steele)
- Fix possible crash in `UPDATE` with a multiple `SET` clause using a sub-`SELECT` as source (Tom Lane)
- Fix crash when zero rows are fed to `json[b]_populate_recordset()` or `json[b]_to_recordset()` (Tom Lane)
- Avoid crash if libxml2 returns a null error message (Sergio Conde Gómez)
- Fix incorrect JIT tuple deforming code for tables with many columns (more than approximately 800) (Andres Freund)
- Fix performance and memory leakage issues in hash-based grouping (Andres Freund)
- Fix spurious grouping-related parser errors caused by inconsistent handling of collation assignment (Andrew Gieth)

In some cases, expressions that should be considered to match were not seen as matching, if they included operations on collatable data types.

- Fix parsing of collation-sensitive expressions in the arguments of a `CALL` statement (Peter Eisentraut)
- Ensure proper cleanup after detecting an error in the argument list of a `CALL` statement (Tom Lane)
- Check whether the comparison function underlying `LEAST()` or `GREATEST()` is leakproof, rather than just assuming it is (Tom Lane)

Actual information leaks from btree comparison functions are typically hard to provoke, but in principle they could happen.

- Fix incorrect planning of queries involving nested loops both above and below a Gather plan node (Tom Lane)

If both levels of nestloop needed to pass the same variable into their right-hand sides, an incorrect plan would be generated.

- Fix incorrect planning of queries in which a lateral reference must be evaluated at a foreign table scan (Tom Lane)
- Fix planner failure when the first column of a row comparison matches an index column, but later column(s) do not, and the index has included (non-key) columns (Tom Lane)
- Fix corner-case underestimation of the cost of a merge join (Tom Lane)

The planner could prefer a merge join when the outer key range is much smaller than the inner key range, even if there are so many duplicate keys on the inner side that this is a poor choice.

- Avoid  $O(N^2)$  planning time growth when a query contains many thousand indexable clauses (Tom Lane)
- Improve planning speed for large inheritance or partitioning table groups (Amit Langote, Etsuro Fujita)
- Improve `ANALYZE`'s handling of concurrently-updated rows (Jeff Janes, Tom Lane)

Previously, rows deleted by an in-progress transaction were omitted from `ANALYZE`'s sample, but this has been found to lead to more inconsistency than including them would do. In effect, the sample now corresponds to an MVCC snapshot as of `ANALYZE`'s start time.

- Make `TRUNCATE` ignore inheritance child tables that are temporary tables of other sessions (Amit Langote, Michael Paquier)

This brings `TRUNCATE` into line with the behavior of other commands. Previously, such cases usually ended in failure.

- Fix `TRUNCATE` to update the statistics counters for the right table (Tom Lane)

If the truncated table had a `TOAST` table, that table's counters were reset instead.

- Process `ALTER TABLE ONLY ADD COLUMN IF NOT EXISTS` correctly (Greg Stark)
- Allow `UNLISTEN` in hot-standby mode (Shay Rojansky)

This is necessarily a no-op, because `LISTEN` isn't allowed in hot-standby mode; but allowing the dummy operation simplifies session-state-reset logic in clients.

- Fix missing role dependencies in some schema and data type permissions lists (Tom Lane)

In some cases it was possible to drop a role to which permissions had been granted. This caused no immediate problem, but a subsequent dump/reload or upgrade would fail, with symptoms involving attempts to grant privileges to all-numeric role names.

- Prevent use of a session's temporary schema within a two-phase transaction (Michael Paquier)

Accessing a temporary table within such a transaction has been forbidden for a long time, but it was still possible to cause problems with other operations on temporary objects.

- Ensure relation caches are updated properly after adding or removing foreign key constraints (Álvaro Herrera)

This oversight could result in existing sessions failing to enforce a newly-created constraint, or continuing to enforce a dropped one.

- Ensure relation caches are updated properly after renaming constraints (Amit Langote)
- Fix replay of GiST index micro-vacuum operations so that concurrent hot-standby queries do not see inconsistent state (Alexander Korotkov)
- Prevent empty GIN index pages from being reclaimed too quickly, causing failures of concurrent searches (Andrey Borodin, Alexander Korotkov)
- Fix edge-case failures in float-to-integer coercions (Andrew Gierth, Tom Lane)

Values very slightly above the maximum valid integer value might not be rejected, and then would overflow, producing the minimum valid integer instead. Also, values that should round to the minimum or maximum integer value might be incorrectly rejected.

- Fix parsing of space-separated lists of host names in the `ldapserver` parameter of LDAP authentication entries in `pg_hba.conf` (Thomas Munro)

- When making a PAM authentication request, don't set the `PAM_RHOST` variable if the connection is via a Unix socket (Thomas Munro)

Previously that variable would be set to `[local]`, which is at best unhelpful, since it's supposed to be a host name.

- Disallow setting `client_min_messages` higher than `ERROR` (Jonah Harris, Tom Lane)

Previously, it was possible to set this variable to `FATAL` or `PANIC`, which had the effect of suppressing transmission of ordinary error messages to the client. However, that's contrary to guarantees that are given in the PostgreSQL wire protocol specification, and it caused some clients to become very confused. In released branches, fix this by silently treating such settings as meaning `ERROR` instead. Version 12 and later will reject those alternatives altogether.

- Fix `ecpglib` to use `uselocale()` or `_configthreadlocale()` in preference to `setlocale()` (Michael Meskes, Tom Lane)

Since `setlocale()` is not thread-local, and might not even be thread-safe, the previous coding caused problems in multi-threaded `ecpg` applications.

- Fix incorrect results for numeric data passed through an `ecpg SQLDA` (SQL Descriptor Area) (Daisuke Higuchi)

Values with leading zeroes were not copied correctly.

- Fix `psql`'s `\g target` meta-command to work with `COPY TO STDOUT` (Daniel Vérité)

Previously, the `target` option was ignored, so that the copy data always went to the current query output target.

- Make `psql`'s LaTeX output formats render special characters properly (Tom Lane)

Backslash and some other ASCII punctuation characters were not rendered correctly, leading to document syntax errors or wrong characters in the output.

- Make `pgbench`'s random number generation fully deterministic and platform-independent when `--random-seed=N` is specified (Fabien Coelho, Tom Lane)

On any specific platform, the sequence obtained with a particular value of `N` will probably be different from what it was before this patch.

- Fix `pg_basebackup` and `pg_verify_checksums` to ignore temporary files appropriately (Michael Banck, Michael Paquier)

- Fix `pg_dump`'s handling of materialized views with indirect dependencies on primary keys (Tom Lane)

This led to mis-labeling of such views' dump archive entries, causing harmless warnings about "archive items not in correct section order"; less harmlessly, selective-restore options depending on those labels, such as `--section`, might misbehave.

- Make `pg_dump` include `ALTER INDEX SET STATISTICS` commands (Michael Paquier)

When the ability to attach statistics targets to index expressions was added, we forgot to teach `pg_dump` about it, so that such settings were lost in dump/reload.

- Fix `pg_dump`'s dumping of tables that have OIDs (Peter Eisentraut)

The `WITH OIDS` clause was omitted if it needed to be applied to the first table to be dumped.

- Avoid null-pointer-dereference crash on some platforms when `pg_dump` or `pg_restore` tries to report an error (Tom Lane)
- Prevent false index-corruption reports from `contrib/amcheck` caused by inline-compressed data (Peter Geoghegan)

- Properly disregard `SIGPIPE` errors if `COPY FROM PROGRAM` stops reading the program's output early (Tom Lane)

This case isn't actually reachable directly with `COPY`, but it can happen when using `contrib/file_fdw`.

- Fix `contrib/hstore` to calculate correct hash values for empty `hstore` values that were created in version 8.4 or before (Andrew Gierth)

The previous coding did not give the same result as for an empty `hstore` value created by a newer version, thus potentially causing wrong results in hash joins or hash aggregation. It is advisable to reindex any hash indexes built on `hstore` columns, if the table might contain data that was originally stored as far back as 8.4 and was never dumped/reloaded since then.

- Avoid crashes and excessive runtime with large inputs to `contrib/intarray`'s `gist__int_ops` index support (Andrew Gierth)
- In `configure`, look for `python3` and then `python2` if `python` isn't found (Peter Eisentraut)

This allows PL/Python to be configured without explicitly specifying `PYTHON` on platforms that no longer provide an unversioned `python` executable.

- Include JIT-related headers in the installed set of header files (Donald Dong)
- Support new Makefile variables `PG_CFLAGS`, `PG_CXXFLAGS`, and `PG_LDFLAGS` in `pgxs` builds (Christoph Berg)

This simplifies customization of extension build processes.

- Fix Perl-coded build scripts to not assume `."` is in the search path, since recent Perl versions don't include that (Andrew Dunstan)
- Fix server command-line option parsing problems on OpenBSD (Tom Lane)
- Relocate call of `set_rel_pathlist_hook` so that extensions can use it to supply partial paths for parallel queries (KaiGai Kohei)

This is not expected to affect existing use-cases.

- Update time zone data files to `tzdata` release 2018i for DST law changes in Kazakhstan, Metlakatla, and Sao Tome and Principe. Kazakhstan's Qyzylorda zone is split in two, creating a new zone Asia/Qostanay, as some areas did not change UTC offset. Historical corrections for Hong Kong and numerous Pacific islands.

## E.45. Release 11.1

**Release date:** 2018-11-08

This release contains a variety of fixes from 11.0. For information about new features in major release 11, see [Section E.46](#).

### E.45.1. Migration to Version 11.1

A dump/restore is not required for those running 11.X.

However, if you use the `pg_stat_statements` extension, see the changelog entry below about that.

### E.45.2. Changes

- Ensure proper quoting of transition table names when `pg_dump` emits `CREATE TRIGGER ... REF-RENCING` commands (Tom Lane)

This oversight could be exploited by an unprivileged user to gain superuser privileges during the next dump/reload or `pg_upgrade` run. (CVE-2018-16850)

- Apply the tablespace specified for a partitioned index when creating a child index (Álvaro Herrera)  
Previously, child indexes were always created in the default tablespace.

- Fix NULL handling in parallel hashed multi-batch left joins (Andrew Gierth, Thomas Munro)

Outer-relation rows with null values of the hash key were omitted from the join result.

- Fix incorrect processing of an array-type coercion expression appearing within a `CASE` clause that has a constant test expression (Tom Lane)
- Fix incorrect expansion of tuples lacking recently-added columns (Andrew Dunstan, Amit Langote)

This is known to lead to crashes in triggers on tables with recently-added columns, and could have other symptoms as well.

- Fix bugs with named or defaulted arguments in `CALL` argument lists (Tom Lane, Pavel Stehule)
- Fix strictness check for strict aggregates with `ORDER BY` columns (Andrew Gierth, Andres Freund)

The strictness logic incorrectly ignored rows for which the `ORDER BY` value(s) were null.

- Disable `recheck_on_update` optimization (Tom Lane)

This new-in-v11 feature turns out not to have been ready for prime time. Disable it until something can be done about it.

- Prevent creation of a partition in a trigger attached to its parent table (Amit Langote)

Ideally we'd allow that, but for the moment it has to be blocked to avoid crashes.

- Fix problems with applying `ON COMMIT DELETE ROWS` to a partitioned temporary table (Amit Langote)
- Fix character-class checks to not fail on Windows for Unicode characters above U+FFFF (Tom Lane, Kenji Uno)

This bug affected full-text-search operations, as well as `contrib/ltree` and `contrib/pg_trgm`.

- Ensure that the server will process already-received `NOTIFY` and `SIGTERM` interrupts before waiting for client input (Jeff Janes, Tom Lane)
- Fix memory leak in repeated SP-GiST index scans (Tom Lane)

This is only known to amount to anything significant in cases where an exclusion constraint using SP-GiST receives many new index entries in a single command.

- Prevent starting the server with `wal_level` set to too low a value to support an existing replication slot (Andres Freund)
- Fix `psql`, as well as documentation examples, to call `PQconsumeInput()` before each `PQnotifies()` call (Tom Lane)

This fixes cases in which `psql` would not report receipt of a `NOTIFY` message until after the next command.

- Fix `pg_verify_checksums`'s determination of which files to check the checksums of (Michael Paquier)

In some cases it complained about files that are not expected to have checksums.

- In `contrib/pg_stat_statements`, disallow the `pg_read_all_stats` role from executing `pg_stat_statements_reset()` (Haribabu Kommi)

`pg_read_all_stats` is only meant to grant permission to read statistics, not to change them, so this grant was incorrect.

To cause this change to take effect, run `ALTER EXTENSION pg_stat_statements UPDATE` in each database where `pg_stat_statements` has been installed. (A database freshly created in 11.0 should not need this, but a database upgraded from a previous release probably still contains the old version of `pg_stat_statements`. The `UPDATE` command is harmless if the module was already updated.)

- Rename red-black tree support functions to use `rbt` prefix not `rb` prefix (Tom Lane)

This avoids name collisions with Ruby functions, which broke PL/Ruby. It's hoped that there are no other affected extensions.

- Fix build problems on macOS 10.14 (Mojave) (Tom Lane)

Adjust `configure` to add an `-isysroot` switch to `CPPFLAGS`; without this, PL/Perl and PL/Tcl fail to configure or build on macOS 10.14. The specific `sysroot` used can be overridden at configure time or build time by setting the `PG_SYSROOT` variable in the arguments of `configure` or `make`.

It is now recommended that Perl-related extensions write `$(perl_includespec)` rather than `-I$(perl_archlibexp)/CORE` in their compiler flags. The latter continues to work on most platforms, but not recent macOS.

Also, it should no longer be necessary to specify `--with-tclconfig` manually to get PL/Tcl to build on recent macOS releases.

- Fix MSVC build and regression-test scripts to work on recent Perl versions (Andrew Dunstan)

Perl no longer includes the current directory in its search path by default; work around that.

- On Windows, allow the regression tests to be run by an Administrator account (Andrew Dunstan)

To do this safely, `pg_regress` now gives up any such privileges at startup.

- Update time zone data files to tzdata release 2018g for DST law changes in Chile, Fiji, Morocco, and Russia (Volgograd), plus historical corrections for China, Hawaii, Japan, Macau, and North Korea.

## E.46. Release 11

**Release date:** 2018-10-18

### E.46.1. Overview

Major enhancements in PostgreSQL 11 include:

- Improvements to partitioning functionality, including:
  - Add support for partitioning by a hash key
  - Add support for `PRIMARY KEY`, `FOREIGN KEY`, indexes, and triggers on partitioned tables
  - Allow creation of a “default” partition for storing data that does not match any of the remaining partitions
  - `UPDATE` statements that change a partition key column now cause affected rows to be moved to the appropriate partitions
  - Improve `SELECT` performance through enhanced partition elimination strategies during query planning and execution
- Improvements to parallelism, including:
  - `CREATE INDEX` can now use parallel processing while building a B-tree index
  - Parallelization is now possible in `CREATE TABLE ... AS`, `CREATE MATERIALIZED VIEW`, and certain queries using `UNION`

- Parallelized hash joins and parallelized sequential scans now perform better
- SQL stored procedures that support embedded transactions
- Optional Just-in-Time (JIT) compilation for some SQL code, speeding evaluation of expressions
- Window functions now support all framing options shown in the SQL:2011 standard, including `RANGE distance PRECEDING/FOLLOWING, GROUPS mode`, and frame exclusion options
- Covering indexes can now be created, using the `INCLUDE` clause of `CREATE INDEX`
- Many other useful performance improvements, including the ability to avoid a table rewrite for `ALTER TABLE ... ADD COLUMN` with a non-null column default

The above items are explained in more detail in the sections below.

## E.46.2. Migration to Version 11

A dump/restore using `pg_dumpall` or use of `pg_upgrade` or logical replication is required for those wishing to migrate data from any previous release. See [Section 18.6](#) for general information on migrating to new major releases.

Version 11 contains a number of changes that may affect compatibility with previous releases. Observe the following incompatibilities:

- Make `pg_dump` dump the properties of a database, not just its contents (Haribabu Kommi)

Previously, attributes of the database itself, such as database-level `GRANT/REVOKE` permissions and `ALTER DATABASE SET` variable settings, were only dumped by `pg_dumpall`. Now `pg_dump --create` and `pg_restore --create` will restore these database properties in addition to the objects within the database. `pg_dumpall -g` now only dumps role- and tablespace-related attributes. `pg_dumpall`'s complete output (without `-g`) is unchanged.

`pg_dump` and `pg_restore`, without `--create`, no longer dump/restore database-level comments and security labels; those are now treated as properties of the database.

`pg_dumpall`'s output script will now always create databases with their original locale and encoding, and hence will fail if the locale or encoding name is unknown to the destination system. Previously, `CREATE DATABASE` would be emitted without these specifications if the database locale and encoding matched the old cluster's defaults.

`pg_dumpall --clean` now restores the original locale and encoding settings of the `postgres` and `template1` databases, as well as those of user-created databases.

- Consider syntactic form when disambiguating function versus column references (Tom Lane)

When  $x$  is a table name or composite column, PostgreSQL has traditionally considered the syntactic forms  $f(x)$  and  $x.f$  to be equivalent, allowing tricks such as writing a function and then using it as though it were a computed-on-demand column. However, if both interpretations are feasible, the column interpretation was always chosen, leading to surprising results if the user intended the function interpretation. Now, if there is ambiguity, the interpretation that matches the syntactic form is chosen.

- Fully enforce uniqueness of table and domain constraint names (Tom Lane)

PostgreSQL expects the names of a table's constraints to be distinct, and likewise for the names of a domain's constraints. However, there was not rigid enforcement of this, and previously there were corner cases where duplicate names could be created.

- Make `power(numeric, numeric)` and `power(float8, float8)` handle NaN inputs according to the POSIX standard (Tom Lane, Dang Minh Huong)

POSIX says that  $\text{NaN} \wedge 0 = 1$  and  $1 \wedge \text{NaN} = 1$ , but all other cases with NaN input(s) should return NaN. `power(numeric, numeric)` just returned NaN in all such cases; now it honors the two excep-

tions. `power(float8, float8)` followed the standard if the C library does; but on some old Unix platforms the library doesn't, and there were also problems on some versions of Windows.

- Prevent `to_number()` from consuming characters when the template separator does not match (Oliver Ford)

Specifically, `SELECT to_number('1234', '9,999')` used to return 134. It will now return 1234. `L` and `TH` now only consume characters that are not digits, positive/negative signs, decimal points, or commas.

- Fix `to_date()`, `to_number()`, and `to_timestamp()` to skip a character for each template character (Tom Lane)

Previously, they skipped one *byte* for each byte of template character, resulting in strange behavior if either string contained multibyte characters.

- Adjust the handling of backslashes inside double-quotes in template strings for `to_char()`, `to_number()`, and `to_timestamp()`.

Such a backslash now escapes the character after it, particularly a double-quote or another backslash.

- Correctly handle relative path expressions in `xmltable()`, `xpath()`, and other XML-handling functions (Markus Winand)

Per the SQL standard, relative paths start from the document node of the XML input document, not the root node as these functions previously did.

- In the [extended query protocol](#), make `statement_timeout` apply to each Execute message separately, not to all commands before Sync (Tatsuo Ishii, Andres Freund)
- Remove the `relhaskey` column from system catalog `pg_class` (Peter Eisentraut)

Applications needing to check for a primary key should consult `pg_index`.

- Replace system catalog `pg_proc`'s `proisagg` and `proiswindow` columns with `prokind` (Peter Eisentraut)

This new column more clearly distinguishes functions, procedures, aggregates, and window functions.

- Correct information schema column `tables.table_type` to return `FOREIGN` instead of `FOREIGN TABLE` (Peter Eisentraut)

This new output matches the SQL standard.

- Change the `ps` process display labels for background workers to match the `pg_stat_activity.backend_type` labels (Peter Eisentraut)
- Cause large object permission checks to happen during large object open, `lo_open()`, not when a read or write is attempted (Tom Lane, Michael Paquier)

If write access is requested and not available, an error will now be thrown even if the large object is never written to.

- Prevent non-superusers from reindexing shared catalogs (Michael Paquier, Robert Haas)

Previously, database owners were also allowed to do this, but now it is considered outside the bounds of their privileges.

- Remove deprecated `adminpack` functions `pg_file_read()`, `pg_file_length()`, and `pg_log-file_rotate()` (Stephen Frost)

Equivalent functionality is now present in the core backend. Existing `adminpack` installs will continue to have access to these functions until they are updated via `ALTER EXTENSION ... UPDATE`.

- Honor the capitalization of double-quoted command options (Daniel Gustafsson)

Previously, option names in certain SQL commands were forcibly lower-cased even if entered with double quotes; thus for example "FillFactor" would be accepted as an index storage option, though properly its name is lower-case. Such cases will now generate an error.

- Remove server parameter `replacement_sort_tuples` (Peter Geoghegan)

Replacement sorts were determined to be no longer useful.

- Remove `WITH` clause in `CREATE FUNCTION` (Michael Paquier)

PostgreSQL has long supported a more standard-compliant syntax for this capability.

- In PL/pgSQL trigger functions, the `OLD` and `NEW` variables now read as `NULL` when not assigned (Tom Lane)

Previously, references to these variables could be parsed but not executed.

## E.46.3. Changes

Below you will find a detailed account of the changes between PostgreSQL 11 and the previous major release.

### E.46.3.1. Server

#### E.46.3.1.1. Partitioning

- Allow the creation of partitions based on hashing a key column (Amul Sul)
- Support indexes on partitioned tables (Álvaro Herrera, Amit Langote)

An “index” on a partitioned table is not a physical index across the whole partitioned table, but rather a template for automatically creating similar indexes on each partition of the table.

If the partition key is part of the index's column set, a partitioned index may be declared `UNIQUE`. It will represent a valid uniqueness constraint across the whole partitioned table, even though each physical index only enforces uniqueness within its own partition.

The new command `ALTER INDEX ATTACH PARTITION` causes an existing index on a partition to be associated with a matching index template for its partitioned table. This provides flexibility in setting up a new partitioned index for an existing partitioned table.

- Allow foreign keys on partitioned tables (Álvaro Herrera)
- Allow `FOR EACH ROW` triggers on partitioned tables (Álvaro Herrera)

Creation of a trigger on a partitioned table automatically creates triggers on all existing and future partitions. This also allows deferred unique constraints on partitioned tables.

- Allow partitioned tables to have a default partition (Jeevan Ladhe, Beena Emerson, Ashutosh Bapat, Rahila Syed, Robert Haas)

The default partition will store rows that don't match any of the other defined partitions, and is searched accordingly.

- `UPDATE` statements that change a partition key column now cause affected rows to be moved to the appropriate partitions (Amit Khandekar)
- Allow `INSERT`, `UPDATE`, and `COPY` on partitioned tables to properly route rows to foreign partitions (Etsuro Fujita, Amit Langote)

This is supported by `postgres_fdw` foreign tables. Since the `ExecForeignInsert` callback function is called for this in a different way than it used to be, foreign data wrappers must be modified to cope with this change.

- Allow faster partition elimination during query processing (Amit Langote, David Rowley, Dilip Kumar)

This speeds access to partitioned tables with many partitions.

- Allow partition elimination during query execution (David Rowley, Beena Emerson)

Previously, partition elimination only happened at planning time, meaning many joins and prepared queries could not use partition elimination.

- In an equality join between partitioned tables, allow matching partitions to be joined directly (Ashutosh Bapat)

This feature is disabled by default but can be enabled by changing `enable_partitionwise_join`.

- Allow aggregate functions on partitioned tables to be evaluated separately for each partition, subsequently merging the results (Jeevan Chalke, Ashutosh Bapat, Robert Haas)

This feature is disabled by default but can be enabled by changing `enable_partitionwise_aggregate`.

- Allow `postgres_fdw` to push down aggregates to foreign tables that are partitions (Jeevan Chalke)

#### **E.46.3.1.2. Parallel Queries**

- Allow parallel building of a btree index (Peter Geoghegan, Rushabh Lathia, Heikki Linnakangas)
- Allow hash joins to be performed in parallel using a shared hash table (Thomas Munro)
- Allow `UNION` to run each `SELECT` in parallel if the individual `SELECT`s cannot be parallelized (Amit Khandekar, Robert Haas, Amul Sul)
- Allow partition scans to more efficiently use parallel workers (Amit Khandekar, Robert Haas, Amul Sul)
- Allow `LIMIT` to be passed to parallel workers (Robert Haas, Tom Lane)

This allows workers to reduce returned results and use targeted index scans.

- Allow single-evaluation queries, e.g., `WHERE` clause aggregate queries, and functions in the target list to be parallelized (Amit Kapila, Robert Haas)
- Add server parameter `parallel_leader_participation` to control whether the leader also executes subplans (Thomas Munro)

The default is enabled, meaning the leader will execute subplans.

- Allow parallelization of commands `CREATE TABLE ... AS`, `SELECT INTO`, and `CREATE MATERIALIZED VIEW` (Haribabu Kommi)
- Improve performance of sequential scans with many parallel workers (David Rowley)
- Add reporting of parallel workers' sort activity in `EXPLAIN` (Robert Haas, Tom Lane)

#### **E.46.3.1.3. Indexes**

- Allow B-tree indexes to include columns that are not part of the search key or unique constraint, but are available to be read by index-only scans (Anastasia Lubennikova, Alexander Korotkov, Teodor Sigaev)

This is enabled by the new `INCLUDE` clause of `CREATE INDEX`. It facilitates building “covering indexes” that optimize specific types of queries. Columns can be included even if their data types don't have B-tree support.

- Improve performance of monotonically increasing index additions (Pavan Deolasee, Peter Geoghegan)

- Improve performance of hash index scans (Ashutosh Sharma)
- Add predicate locking for hash, GiST and GIN indexes (Shubham Barai)

This reduces the likelihood of serialization conflicts in serializable-mode transactions.

#### **E.46.3.1.3.1. SP-Gist**

- Add prefix-match operator `text ^@ text`, which is supported by SP-GiST (Ildus Kurbangaliev)

This is similar to using `var LIKE 'word%'` with a btree index, but it is more efficient.

- Allow polygons to be indexed with SP-GiST (Nikita Glukhov, Alexander Korotkov)
- Allow SP-GiST to use lossy representation of leaf keys (Teodor Sigaev, Heikki Linnakangas, Alexander Korotkov, Nikita Glukhov)

#### **E.46.3.1.4. Optimizer**

- Improve selection of the most common values for statistics (Jeff Janes, Dean Rasheed)

Previously, the most common values (MCVs) were identified based on their frequency compared to all column values. Now, MCVs are chosen based on their frequency compared to the non-MCV values. This improves the robustness of the algorithm for both uniform and non-uniform distributions.

- Improve selectivity estimates for `>=` and `<=` (Tom Lane)

Previously, such cases used the same selectivity estimates as `>` and `<`, respectively, unless the comparison constants are MCVs. This change is particularly helpful for queries involving `BETWEEN` with small ranges.

- Reduce `var = var` to `var IS NOT NULL` where equivalent (Tom Lane)

This leads to better selectivity estimates.

- Improve optimizer's row count estimates for `EXISTS` and `NOT EXISTS` queries (Tom Lane)
- Make the optimizer account for evaluation costs and selectivity of `HAVING` clauses (Tom Lane)

#### **E.46.3.1.5. General Performance**

- Add **Just-in-Time** (JIT) compilation of some parts of query plans to improve execution speed (Andres Freund)

This feature requires LLVM to be available. It is not currently enabled by default, even in builds that support it.

- Allow bitmap scans to perform index-only scans when possible (Alexander Kuzmenkov)
- Update the free space map during `VACUUM` (Claudio Freire)

This allows free space to be reused more quickly.

- Allow `VACUUM` to avoid unnecessary index scans (Masahiko Sawada, Alexander Korotkov)
- Improve performance of committing multiple concurrent transactions (Amit Kapila)
- Reduce memory usage for queries using set-returning functions in their target lists (Andres Freund)
- Improve the speed of aggregate computations (Andres Freund)
- Allow `postgres_fdw` to push `UPDATES` and `DELETES` using joins to foreign servers (Etsuro Fujita)

Previously, only non-join `UPDATES` and `DELETES` were pushed.

- Add support for *large pages* on Windows (Takayuki Tsunakawa, Thomas Munro)

This is controlled by the [huge\\_pages](#) configuration parameter.

#### E.46.3.1.6. Monitoring

- Show memory usage in output from [log\\_statement\\_stats](#), [log\\_parser\\_stats](#), [log\\_planner\\_stats](#), and [log\\_executor\\_stats](#) (Justin Pryzby, Peter Eisentraut)
- Add column [pg\\_stat\\_activity.backend\\_type](#) to show the type of a background worker (Peter Eisentraut)

The type is also visible in `ps` output.

- Make [log\\_autovacuum\\_min\\_duration](#) log skipped tables that are concurrently being dropped (Nathan Bossart)

#### E.46.3.1.6.1. Information Schema

- Add [information\\_schema](#) columns related to table constraints and triggers (Peter Eisentraut)

Specifically, `triggers.action_order`, `triggers.action_reference_old_table`, and `triggers.action_reference_new_table` are now populated, where before they were always null. Also, `table_constraints.enforced` now exists but is not yet usefully populated.

#### E.46.3.1.7. Authentication

- Allow the server to specify more complex [LDAP](#) specifications in search+bind mode (Thomas Munro)

Specifically, `ldapsearchfilter` allows pattern matching using combinations of LDAP attributes.

- Allow LDAP authentication to use encrypted LDAP (Thomas Munro)

We already supported LDAP over TLS by using `ldaptls=1`. This new TLS LDAP method for encrypted LDAP is enabled with `ldapscheme=ldaps` or `ldapurl=ldaps://`.

- Improve logging of LDAP errors (Thomas Munro)

#### E.46.3.1.8. Permissions

- Add [default roles](#) that enable file system access (Stephen Frost)

Specifically, the new roles are: `pg_read_server_files`, `pg_write_server_files`, and `pg_execute_server_program`. These roles now also control who can use server-side `COPY` and the [file\\_fdw](#) extension. Previously, only superusers could use these functions, and that is still the default behavior.

- Allow access to file system functions to be controlled by `GRANT/REVOKE` permissions, rather than superuser checks (Stephen Frost)

Specifically, these functions were modified: `pg_ls_dir()`, `pg_read_file()`, `pg_read_binary_file()`, `pg_stat_file()`.

- Use `GRANT/REVOKE` to control access to `lo_import()` and `lo_export()` (Michael Paquier, Tom Lane)

Previously, only superusers were granted access to these functions.

The compile-time option `ALLOW_DANGEROUS_LO_FUNCTIONS` has been removed.

- Use view owner not session owner when preventing non-password access to [postgres\\_fdw](#) tables (Robert Haas)

PostgreSQL only allows superusers to access `postgres_fdw` tables without passwords, e.g., via `peer`. Previously, the session owner had to be a superuser to allow such access; now the view owner is checked instead.

- Fix invalid locking permission check in `SELECT FOR UPDATE` on views (Tom Lane)

#### E.46.3.1.9. Server Configuration

- Add server setting `ssl_passphrase_command` to allow supplying of the passphrase for SSL key files (Peter Eisentraut)

Also add `ssl_passphrase_command_supports_reload` to specify whether the SSL configuration should be reloaded and `ssl_passphrase_command` called during a server configuration reload.

- Add storage parameter `toast_tuple_target` to control the minimum tuple length before TOAST storage will be considered (Simon Riggs)

The default TOAST threshold has not been changed.

- Allow server options related to memory and file sizes to be specified in units of bytes (Beena Emerson)

The new unit suffix is “B”. This is in addition to the existing units “kB”, “MB”, “GB” and “TB”.

#### E.46.3.1.10. Write-Ahead Log (WAL)

- Allow the WAL file size to be set during `initdb` (Beena Emerson)

Previously, the 16MB default could only be changed at compile time.

- Retain WAL data for only a single checkpoint (Simon Riggs)

Previously, WAL was retained for two checkpoints.

- Fill the unused portion of force-switched WAL segment files with zeros for improved compressibility (Chapman Flack)

#### E.46.3.2. Base Backup and Streaming Replication

- Replicate `TRUNCATE` activity when using logical replication (Simon Riggs, Marco Nenciarini, Peter Eisentraut)
- Pass prepared transaction information to logical replication subscribers (Nikhil Sontakke, Stas Kelvich)
- Exclude unlogged tables, temporary tables, and `pg_internal.init` files from streaming base backups (David Steele)

There is no need to copy such files.

- Allow checksums of heap pages to be verified during streaming base backup (Michael Banck)
- Allow replication slots to be advanced programmatically, rather than be consumed by subscribers (Petr Jelinek)

This allows efficient advancement of replication slots when the contents do not need to be consumed. This is performed by `pg_replication_slot_advance()`.

- Add timeline information to the `backup_label` file (Michael Paquier)

Also add a check that the WAL timeline matches the `backup_label` file's timeline.

- Add host and port connection information to the `pg_stat_wal_receiver` system view (Haribabu Kommi)

#### E.46.3.3. Utility Commands

- Allow `ALTER TABLE` to add a column with a non-null default without doing a table rewrite (Andrew Dunstan, Serge Rielau)

This is enabled when the default value is a constant.

- Allow views to be locked by locking the underlying tables (Yugo Nagata)
- Allow `ALTER INDEX` to set statistics-gathering targets for expression indexes (Alexander Korotkov, Adrien Nayrat)

In `psql`, `\d+` now shows the statistics target for indexes.

- Allow multiple tables to be specified in one `VACUUM` or `ANALYZE` command (Nathan Bossart)

Also, if any table mentioned in `VACUUM` uses a column list, then the `ANALYZE` keyword must be supplied; previously, `ANALYZE` was implied in such cases.

- Add parenthesized options syntax to `ANALYZE` (Nathan Bossart)

This is similar to the syntax supported by `VACUUM`.

- Add `CREATE AGGREGATE` option to specify the behavior of the aggregate's finalization function (Tom Lane)

This is helpful for allowing user-defined aggregate functions to be optimized and to work as window functions.

#### E.46.3.4. Data Types

- Allow the creation of arrays of domains (Tom Lane)

This also allows `array_agg()` to be used on domains.

- Support domains over composite types (Tom Lane)

Also allow PL/Perl, PL/Python, and PL/Tcl to handle composite-domain function arguments and results. Also improve PL/Python domain handling.

- Add casts from `JSONB` scalars to numeric and boolean data types (Anastasia Lubennikova)

#### E.46.3.5. Functions

- Add all [window function](#) framing options specified by SQL:2011 (Oliver Ford, Tom Lane)

Specifically, allow `RANGE mode` to use `PRECEDING` and `FOLLOWING` to select rows having grouping values within plus or minus the specified offset. Add `GROUPS mode` to include plus or minus the number of peer groups. Frame exclusion syntax was also added.

- Add SHA-2 family of hash functions (Peter Eisentraut)

Specifically, `sha224()`, `sha256()`, `sha384()`, `sha512()` were added.

- Add support for 64-bit non-cryptographic hash functions (Robert Haas, Amul Sul)
- Allow `to_char()` and `to_timestamp()` to specify the time zone's offset from UTC in hours and minutes (Nikita Glukhov, Andrew Dunstan)

This is done with format specifications [TZH](#) and [TzM](#).

- Add text search function `websearch_to_tsquery()` that supports a query syntax similar to that used by web search engines (Victor Drobný, Dmitry Ivanov)
- Add functions `json(b)_to_tsvector()` to create a text search query for matching `JSON/JSONB` values (Dmitry Dolgov)

#### E.46.3.6. Server-Side Languages

- Add SQL-level procedures, which can start and commit their own transactions (Peter Eisentraut)

They are created with the new `CREATE PROCEDURE` command and invoked via `CALL`.

The new `ALTER/DROP ROUTINE` commands allow altering/dropping of all routine-like objects, including procedures, functions, and aggregates.

Also, writing `FUNCTION` is now preferred over writing `PROCEDURE` in `CREATE OPERATOR` and `CREATE TRIGGER`, because the referenced object must be a function not a procedure. However, the old syntax is still accepted for compatibility.

- Add transaction control to PL/pgSQL, PL/Perl, PL/Python, PL/Tcl, and SPI server-side languages (Peter Eisentraut)

Transaction control is only available within top-transaction-level procedures and nested `DO` and `CALL` blocks that only contain other `DO` and `CALL` blocks.

- Add the ability to define PL/pgSQL composite-type variables as not null, constant, or with initial values (Tom Lane)
- Allow PL/pgSQL to handle changes to composite types (e.g., record, row) that happen between the first and later function executions in the same session (Tom Lane)

Previously, such circumstances generated errors.

- Add extension `jsonb_plpython` to transform `JSONB` to/from PL/Python types (Anthony Bykov)
- Add extension `jsonb_plperl` to transform `JSONB` to/from PL/Perl types (Anthony Bykov)

#### E.46.3.7. Client Interfaces

- Change `libpq` to disable compression by default (Peter Eisentraut)

Compression is already disabled in modern OpenSSL versions, so that the `libpq` setting had no effect with such libraries.

- Add `DO CONTINUE` option to `ecpg`'s `WHENEVER` statement (Vinayak Pokale)

This generates a `C continue` statement, causing a return to the top of the contained loop when the specified condition occurs.

- Add an `ecpg` mode to enable Oracle Pro\*C-style handling of char arrays.

This mode is enabled with `-C`.

#### E.46.3.8. Client Applications

- Add `psql` command `\gdesc` to display the names and types of the columns in a query result (Pavel Stehule)
- Add `psql` variables to report query activity and errors (Fabien Coelho)

Specifically, the new variables are `ERROR`, `SQLSTATE`, `ROW_COUNT`, `LAST_ERROR_MESSAGE`, and `LAST_ERROR_SQLSTATE`.

- Allow `psql` to test for the existence of a variable (Fabien Coelho)

Specifically, the syntax `:{?variable_name}` allows a variable's existence to be tested in an `\if` statement.

- Allow environment variable `PSQL_PAGER` to control `psql`'s pager (Pavel Stehule)

This allows `psql`'s default pager to be specified as a separate environment variable from the pager for other applications. `PAGER` is still honored if `PSQL_PAGER` is not set.

- Make `psql`'s `\d+` command always show the table's partitioning information (Amit Langote, Ashutosh Bapat)

Previously, partition information would not be displayed for a partitioned table if it had no partitions. Also indicate which partitions are themselves partitioned.

- Ensure that `psql` reports the proper user name when prompting for a password (Tom Lane)

Previously, combinations of `-U` and a user name embedded in a URI caused incorrect reporting. Also suppress the user name before the password prompt when `--password` is specified.

- Allow `quit` and `exit` to exit `psql` when given with no prior input (Bruce Momjian)

Also print hints about how to exit when `quit` and `exit` are used alone on a line while the input buffer is not empty. Add a similar hint for `help`.

- Make `psql` hint at using control-D when `\q` is entered alone on a line but ignored (Bruce Momjian)

For example, `\q` does not exit when supplied in character strings.

- Improve tab completion for `ALTER INDEX RESET/SET` (Masahiko Sawada)
- Add infrastructure to allow `psql` to adapt its tab completion queries based on the server version (Tom Lane)

Previously, tab completion queries could fail against older servers.

#### **E.46.3.8.2. `pgbench`**

- Add `pgbench` expression support for NULLs, booleans, and some functions and operators (Fabien Coelho)
- Add `\if` conditional support to `pgbench` (Fabien Coelho)
- Allow the use of non-ASCII characters in `pgbench` variable names (Fabien Coelho)
- Add `pgbench` option `--init-steps` to control the initialization steps performed (Masahiko Sawada)
- Add an approximately Zipfian-distributed random generator to `pgbench` (Alik Khilazhev)
- Allow the random seed to be set in `pgbench` (Fabien Coelho)
- Allow `pgbench` to do exponentiation with `pow()` and `power()` (Raúl Marín Rodríguez)
- Add hashing functions to `pgbench` (Ildar Musin)
- Make `pgbench` statistics more accurate when using `--latency-limit` and `--rate` (Fabien Coelho)

#### **E.46.3.9. Server Applications**

- Add an option to `pg_basebackup` that creates a named replication slot (Michael Banck)

The option `--create-slot` creates the named replication slot (`--slot`) when the WAL streaming method (`--wal-method=stream`) is used.

- Allow `initdb` to set group read access to the data directory (David Steele)

This is accomplished with the new `initdb` option `--allow-group-access`. Administrators can also set group permissions on the empty data directory before running `initdb`. Server variable `data_directory_mode` allows reading of data directory group permissions.

- Add `pg_verify_checksums` tool to verify database checksums while offline (Magnus Hagander)
- Allow `pg_resetwal` to change the WAL segment size via `--wal-segsize` (Nathan Bossart)
- Add long options to `pg_resetwal` and `pg_controldata` (Nathan Bossart, Peter Eisentraut)

- Add `pg_receivewal` option `--no-sync` to prevent synchronous WAL writes, for testing (Michael Paquier)
- Add `pg_receivewal` option `--endpos` to specify when WAL receiving should stop (Michael Paquier)
- Allow `pg_ctl` to send the `SIGKILL` signal to processes (Andres Freund)

This was previously unsupported due to concerns over possible misuse.

- Reduce the number of files copied by `pg_rewind` (Michael Paquier)
- Prevent `pg_rewind` from running as `root` (Michael Paquier)

#### **E.46.3.9.1. `pg_dump`, `pg_dumpall`, `pg_restore`**

- Add `pg_dumpall` option `--encoding` to control output encoding (Michael Paquier)

`pg_dump` already had this option.

- Add `pg_dump` option `--load-via-partition-root` to force loading of data into the partition's root table, rather than the original partition (Rushabh Lathia)

This is useful if the system to be loaded to has different collation definitions or endianness, possibly requiring rows to be stored in different partitions than previously.

- Add an option to suppress dumping and restoring database object comments (Robins Tharakan)

The new `pg_dump`, `pg_dumpall`, and `pg_restore` option is `--no-comments`.

#### **E.46.3.10. Source Code**

- Add PGXS support for installing include files (Andrew Gierth)

This supports creating extension modules that depend on other modules. Formerly there was no easy way for the dependent module to find the referenced one's include files. Several existing `contrib` modules that define data types have been adjusted to install relevant files. Also, PL/Perl and PL/Python now install their include files, to support creation of transform modules for those languages.

- Install `errcodes.txt` to allow extensions to access the list of error codes known to PostgreSQL (Thomas Munro)
- Convert documentation to DocBook XML (Peter Eisentraut, Alexander Lakhin, Jürgen Purtz)

The file names still use an `sgml` extension for compatibility with back branches.

- Use `stdbool.h` to define type `bool` on platforms where it's suitable, which is most (Peter Eisentraut)

This eliminates a coding hazard for extension modules that need to include `stdbool.h`.

- Overhaul the way that initial system catalog contents are defined (John Naylor)

The initial data is now represented in Perl data structures, making it much easier to manipulate mechanically.

- Prevent extensions from creating custom server parameters that take a quoted list of values (Tom Lane)

This cannot be supported at present because knowledge of the parameter's property would be required even before the extension is loaded.

- Add ability to use channel binding when using `SCRAM` authentication (Michael Paquier)

Channel binding is intended to prevent man-in-the-middle attacks, but `SCRAM` cannot prevent them unless it can be forced to be active. Unfortunately, there is no way to do that in `libpq`. Support for it is expected in future versions of `libpq` and in interfaces not built using `libpq`, e.g., `JDBC`.

- Allow background workers to attach to databases that normally disallow connections (Magnus Hagander)
- Add support for hardware CRC calculations on ARMv8 (Yuqi Gu, Heikki Linnakangas, Thomas Munro)
- Speed up lookups of built-in functions by OID (Andres Freund)

The previous binary search has been replaced by a lookup array.

- Speed up construction of query results (Andres Freund)
- Improve speed of access to system caches (Andres Freund)
- Add a generational memory allocator which is optimized for serial allocation/deallocation (Tomas Vondra)

This reduces memory usage for logical decoding.

- Make the computation of `pg_class.reltuples` by `VACUUM` consistent with its computation by `ANALYZE` (Tomas Vondra)
- Update to use `perltidy` version 20170521 (Tom Lane, Peter Eisentraut)

### E.46.3.11. Additional Modules

- Allow extension `pg_prewarm` to restore the previous shared buffer contents on startup (Mithun Cy, Robert Haas)

This is accomplished by having `pg_prewarm` store the shared buffers' relation and block number data to disk occasionally during server operation, and at shutdown.

- Add `pg_trgm` function `strict_word_similarity()` to compute the similarity of whole words (Alexander Korotkov)

The function `word_similarity()` already existed for this purpose, but it was designed to find similar parts of words, while `strict_word_similarity()` computes the similarity to whole words.

- Allow `btree_gin` to index `bool`, `bpchar`, `name` and `uuid` data types (Matheus Oliveira)
- Allow `cube` and `seg` extensions to perform index-only scans using GiST indexes (Andrey Borodin)
- Allow retrieval of negative cube coordinates using the `~>` operator (Alexander Korotkov)

This is useful for KNN-GiST searches when looking for coordinates in descending order.

- Add Vietnamese letter handling to the `unaccent` extension (Dang Minh Huong, Michael Paquier)
- Enhance `amcheck` to check that each heap tuple has an index entry (Peter Geoghegan)
- Have `adminpack` use the new default file system access roles (Stephen Frost)

Previously, only superusers could call `adminpack` functions; now role permissions are checked.

- Widen `pg_stat_statement`'s query ID to 64 bits (Robert Haas)

This greatly reduces the chance of query ID hash collisions. The query ID can now potentially display as a negative value.

- Remove the `contrib/start-scripts/osx` scripts since they are no longer recommended (use `contrib/start-scripts/macos` instead) (Tom Lane)
- Remove the `chkpss` extension (Peter Eisentraut)

This extension is no longer considered to be a usable security tool or example of how to write an extension.

## E.46.4. Acknowledgments

The following individuals (in alphabetical order) have contributed to this release as patch authors, committers, reviewers, testers, or reporters of issues.

## E.47. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Enterprise 11 release, these prior versions were supported:

- Postgres Pro Enterprise 10: <https://postgrespro.com/docs/enterprise/10/release.html>
- Postgres Pro Enterprise 9.6: <https://postgrespro.com/docs/enterprise/9.6/release.html>

---

# Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding additional modules available in the Postgres Pro Enterprise distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers the extensions and other server plug-in modules. [Appendix G](#) covers the utility programs.

In Postgres Pro Enterprise, these modules are made available as a separate subpackage `postgrespro-ent-11-contrib`.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. In Postgres Pro, and PostgreSQL 9.1 and later, this is done by executing a [CREATE EXTENSION](#) command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command must be run by a database superuser. This registers the new SQL objects in the current database only, so you need to run this command in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

If your database was brought forward by dump and reload from a pre-9.1 version of PostgreSQL, and you had been using the pre-9.1 version of the module in it, you should instead do

```
CREATE EXTENSION module_name FROM unpackaged;
```

This will update the pre-9.1 objects of the module into a proper *extension* object. Future updates to the module will be managed by [ALTER EXTENSION](#). For more information about extension updates, see [Section 39.16](#).

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared\\_preload\\_libraries](#). See the documentation of each module for details.

## F.1. adminpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to the superuser by default but may be allowed to other users by using the `GRANT` command.

The functions shown in [Table F.1](#) provide write access to files on the machine hosting the server. (See also the functions in [Table 9.88](#), which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given one of the `pg_read_server_files`, or `pg_write_server_files` roles, as appropriate for the function, but either a relative or absolute path is allowable.

**Table F.1. adminpack Functions**

| Name                                                                                    | Return Type               | Description                                                    |
|-----------------------------------------------------------------------------------------|---------------------------|----------------------------------------------------------------|
| <code>pg_catalog.pg_file_write(filename text, data text, append boolean)</code>         | <code>bigint</code>       | Write, or append to, a text file                               |
| <code>pg_catalog.pg_file_rename(oldname text, newname text [, archivename text])</code> | <code>boolean</code>      | Rename a file                                                  |
| <code>pg_catalog.pg_file_unlink(filename text)</code>                                   | <code>boolean</code>      | Remove a file                                                  |
| <code>pg_catalog.pg_logdir_ls()</code>                                                  | <code>setof record</code> | List the log files in the <code>log_directory</code> directory |

`pg_file_write` writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_rename` renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the [log\\_directory](#) directory. The [log\\_filename](#) parameter must have its default setting (`postgresql-%Y-%m-%d_%H%M%S.log`) to use this function.

## F.2. amcheck

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations. If the structure appears to be valid, no error is raised.

The functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 39.15.3](#) for details of operator class support functions.

`amcheck` functions may only be used by superusers.

### F.2.1. Functions

`bt_index_check(index regclass, heapallindexed boolean)` returns void

`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```
test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
```

```

        c.relname,
        c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;

```

| bt_index_check | relname                         | relpages |
|----------------|---------------------------------|----------|
|                | pg_depend_reference_index       | 43       |
|                | pg_depend_depender_index        | 40       |
|                | pg_proc_proname_args_nsp_index  | 31       |
|                | pg_description_o_c_o_index      | 21       |
|                | pg_attribute_relid_attnam_index | 14       |
|                | pg_proc_oid_index               | 10       |
|                | pg_attribute_relid_attnum_index | 9        |
|                | pg_amproc_fam_proc_index        | 5        |
|                | pg_amop_opr_fam_index           | 5        |
|                | pg_amop_fam_strat_index         | 5        |

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean)` returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the `heapallindexed` argument is `true`, the function verifies the presence of all heap tuples that should be found within the index, and that there are no missing downlinks in the index structure. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is

checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when Hot Standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

## F.2.2. Optional *heapallindexed* verification

When the *heapallindexed* argument to verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

## F.2.3. Using *amcheck* effectively

*amcheck* can be effective at detecting various types of failure modes that [data page checksums](#) will always fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a master server and a standby server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 23.1](#) and [Section 23.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call *amcheck* functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When `heapallindexed` verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

## F.2.4. Repairing corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

## F.3. aqo

The `aqo` module is a Postgres Pro Enterprise extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, `aqo` improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

The `aqo` module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants only, they belong to the same class. For each query class, `aqo` stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, `aqo` builds a new query plan and uses it for the next query of the same class. `aqo` test runs have shown significant performance improvements for complex queries.

### Important

Query optimization using the `aqo` module is not supported on standby.

### F.3.1. Installation and Setup

The `aqo` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `aqo`:

1. Add `aqo` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'aqo'
```

The `aqo` library must be preloaded at the server startup since adaptive query optimization needs to be enabled per cluster. Otherwise, `aqo` will only be used for the session in which you created the `aqo` extension.

2. Create the `aqo` extension using the following query:

```
CREATE EXTENSION aqo;
```

Once the extension is created, you can start optimizing queries.

To disable `aqo` at the cluster level and remove all the collected statistics, run:

```
DROP EXTENSION aqo;
```

### F.3.1.1. Configuration

By default, `aqo` does not affect query performance. To enable adaptive query optimization for your database, add the `aqo.mode` variable to your `postgresql.conf` file and reload the cluster. Depending on your database usage model, you can choose between the following modes:

- `intelligent` — this mode auto-tunes your queries based on statistics collected per query class.
- `forced` — this mode collects statistics for all queries altogether without any classification.
- `controlled` — this mode uses the default planner for all new queries, but continues using the previously specified planning settings for already known query classes, if any.
- `learn` — this mode collects statistics on all the executed queries and updates the data for query classes.
- `disabled` — this mode disables `aqo` for all queries, even for the known query classes. You can use this mode to temporarily disable `aqo` without losing the collected statistics and configuration.

To dynamically change the `aqo` settings in your current session, run the following command:

```
SET aqo.mode = 'mode';
```

where `mode` is the name of the operation mode to use.

#### Important

The `intelligent` mode of `aqo` may not work well if the queries in your workload are of multiple different classes. In this case, you can try resetting the mode to `controlled`.

## F.3.2. Usage

### F.3.2.1. Choosing Operation Mode for Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can use the `intelligent` mode to improve planning for these queries. In this mode, `aqo` analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the `aqo` extension falls back to the default query planner.

#### Note

You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the [Section 14.1](#).

Since the `intelligent` mode tries to learn separately for different query classes, `aqo` may fail to provide performance improvements if the classes of the queries in the workload are constantly changing. For such dynamic workloads, reset the `aqo` extension to the `controlled` mode, or try using the `forced` mode.

In the `forced` mode, `aqo` does not classify the collected statistics by query classes and tries to optimize all queries together. This mode can help you optimize workloads with multiple different query classes, and

it consumes less memory than the intelligent mode. However, since the `forced` mode lacks intelligent tuning, performance may decrease for some queries. If you see performance issues in this mode, switch `aqo` to the `controlled` mode.

In the `controlled` mode, `aqo` does not collect statistics for new query classes, so they will not be optimized. For known query classes, `aqo` will continue collecting statistics and using optimized planning algorithms.

The `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it doesn't provide intelligent tuning.

If you want to fully disable `aqo`, you can switch `aqo` to the `disabled` mode. In this case, the default planner is used for all queries, but the collected statistics and `aqo` settings are saved and can be used in the future.

### F.3.2.2. Fine-Tuning `aqo`

You must have superuser rights to access `aqo` tables and configure advanced query settings.

When run in the `intelligent` mode, `aqo` assigns a unique hash value to each query class to separate the collected statistics. If you switch to the `forced` mode, the statistics for all untracked query classes is stored in a common query class with hash 0. You can view all the processed query classes and their corresponding hash values in the `aqo_query_texts` table:

```
SELECT * FROM aqo_query_texts;
```

Each query class has its own optimization settings. These settings are stored in the `aqo_queries` table:

```
SELECT * FROM aqo_queries;
```

For each query class, the following settings are available:

- `query_hash` stores the hash value that uniquely identifies the query class.
- `learn_aqo` enables statistics collection for this query class.
- `use_aqo` enables `aqo` cardinality prediction for the next execution of this query class.
- `fspace_hash` is a unique identifier of the separate space in which the statistics for this query class is collected. By default, `fspace_hash` is equal to `query_hash`.
- `auto_tuning` shows whether `aqo` tries to change other settings for the given query. By default, `auto-tuning` is enabled in the `intelligent` mode.

You can manually change these settings to adjust optimization for a particular query class. For example:

```
-- Add a new query class into the aqo_queries table:

SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';

-- Disable auto_tuning, enable both learn_aqo and use_aqo
-- for this query class:

UPDATE aqo_queries SET use_aqo=true, learn_aqo=true, auto_tuning=false
  WHERE query_hash = (SELECT query_hash from aqo_query_texts
  WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');

-- Run EXPLAIN ANALYZE until the plan changes:

EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
```

```
-- Disable learning to stop statistics collection
-- and use the optimized plan:
```

```
UPDATE aqo_queries SET learn_aqo=false
WHERE query_hash = (SELECT query_hash from aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

If your data or query distribution is rapidly changing, learning new statistics will take longer than usual. In this case, obsolete statistics may affect performance. To speed up `aqo` learning, reset the statistics. To remove all the collected machine learning statistics, run the following command:

```
DELETE FROM aqo_data;
```

Alternatively, you can specify a particular query class to reset by providing its hash value in the `fspace_hash` option. For example:

```
DELETE FROM aqo_data WHERE fspace_hash = (SELECT fspace_hash FROM aqo_queries
WHERE query_hash = (SELECT query_hash from aqo_query_texts
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;'));
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
UPDATE aqo_queries SET auto_tuning=false WHERE query_hash = 'hash';
```

where *hash* is the hash value for this query class. As a result, `aqo` disables automatic changing of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
UPDATE aqo_queries SET learn_aqo=false WHERE query_hash = 'hash';
```

where *hash* is the hash value for this query class.

To fully disable `aqo` for all queries and use the default PostgreSQL query planner, run:

```
UPDATE aqo_queries SET use_aqo=false, learn_aqo=false, auto_tuning=false;
```

## F.3.3. Reference

### F.3.3.1. Configuration Variables

#### F.3.3.1.1. `aqo.mode`

Defines `aqo` operation mode.

**Table F.2. `aqo.mode` Options**

| Option                   | Description                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>intelligent</code> | Auto-tunes your queries based on statistics collected per query class.                                                                           |
| <code>forced</code>      | Collects statistics for all queries altogether without any classification.                                                                       |
| <code>controlled</code>  | <b>Default.</b> Uses the default planner for all new queries, but can reuse the collected statistics for already known query classes, if any.    |
| <code>learn</code>       | Collects statistics on all the executed queries and updates the data for query classes.                                                          |
| <code>disabled</code>    | Fully disables <code>aqo</code> for all queries. The collected statistics and <code>aqo</code> settings are saved and can be used in the future. |

### F.3.3.2. Tables

#### Important

You can manually change optimization settings in the `aqo_queries` table. You may also modify other tables, but only if you understand the logic of adaptive query optimization.

#### F.3.3.2.1. `aqo_query_texts` Table

The `aqo_query_texts` table classifies all the query classes processed by `aqo`. For each query class, the table contains the text of the first analyzed query of this class.

**Table F.3. `aqo_query_texts` Table**

| Column Name             | Description                                                       |
|-------------------------|-------------------------------------------------------------------|
| <code>query_hash</code> | Stores the hash value that uniquely identifies the query class.   |
| <code>query_text</code> | Provides the text of the first analyzed query of the given class. |

#### F.3.3.2.2. `aqo_queries` Table

The `aqo_queries` table stores optimization settings for different query classes.

**Table F.4. `aqo_queries` Table**

| Setting                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>query_hash</code>  | Stores the hash value that uniquely identifies the query class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>learn_aqo</code>   | Enables statistics collection for this query class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>use_aqo</code>     | Enables <code>aqo</code> cardinality prediction for the next execution of this query class. If cost estimation model is incomplete, this may slow down query execution.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>fspace_hash</code> | Provides a unique identifier of the separate space in which the statistics for this query class is collected. By default, <code>fspace_hash</code> is equal to <code>query_hash</code> . You can change this setting to a different <code>query_hash</code> to optimize different query classes together. It may decrease the amount of memory for models and even improve query execution performance. However, changing this setting may cause unexpected <code>aqo</code> behavior, so make sure to use it only if you know what you are doing. |
| <code>auto_tuning</code> | Shows whether <code>aqo</code> tries to tune other settings for the given query. By default, auto-tuning is enabled in the intelligent mode. In other modes, new queries are not appended to <code>aqo_queries</code> automatically. You can change this behavior by setting the <code>auto_tuning</code> variable to <code>true</code> .                                                                                                                                                                                                          |

#### F.3.3.2.3. `aqo_data` Table

The `aqo_data` table contains machine learning data for cardinality estimation refinement. To forget all the collected statistics for a particular query class, you can delete all rows from `aqo_data` with the corresponding `fspace_hash`.

#### F.3.3.2.4. `aqo_query_stat` Table

The `aqo_query_stat` table stores statistics on query execution, by query class. The `aqo` extension uses this data when the `auto_tuning` option is enabled for a particular query class.

**Table F.5. `aqo_query_stat` Table**

| Data                                       | Description                                                                              |
|--------------------------------------------|------------------------------------------------------------------------------------------|
| <code>execution_time_with_aqo</code>       | Execution time for queries run with <code>aqo</code> enabled.                            |
| <code>execution_time_without_aqo</code>    | Execution time for queries run with <code>aqo</code> disabled.                           |
| <code>planning_time_with_aqo</code>        | Planning time for queries run with <code>aqo</code> enabled.                             |
| <code>planning_time_without_aqo</code>     | Planning time for queries run with <code>aqo</code> disabled.                            |
| <code>cardinality_error_with_aqo</code>    | Cardinality estimation error in the selected query plans with <code>aqo</code> enabled.  |
| <code>cardinality_error_without_aqo</code> | Cardinality estimation error in the selected query plans with <code>aqo</code> disabled. |
| <code>executions_with_aqo</code>           | Number of queries run with <code>aqo</code> enabled.                                     |
| <code>executions_without_aqo</code>        | Number of queries run with <code>aqo</code> disabled.                                    |

#### F.3.4. Author

Oleg Ivanov

### F.4. `auth_delay`

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via [shared\\_preload\\_libraries](#) in `postgresql.conf`.

#### F.4.1. Configuration Parameters

`auth_delay.milliseconds` (int)

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

#### F.4.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

### F.5. `auto_explain`

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run [EXPLAIN](#) by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in [session\\_preload\\_libraries](#) or [shared\\_preload\\_libraries](#) in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

### F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration` (integer)

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to zero logs all plans. Minus-one (the default) disables logging of plans. For example, if you set it to `250ms` then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_analyze` (boolean)

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

#### Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

`auto_explain.sample_rate` (real)

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

## F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms planning: 0.548 ms plan:
       Query Text: SELECT count(*)
                   FROM pg_class, pg_index
                   WHERE oid = indrelid AND indisunique;
Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
loops=1)
-> Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
loops=1)
       Hash Cond: (pg_class.oid = pg_index.indrelid)
-> Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255 loops=1)
-> Hash  (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
loops=1)
       Buckets: 1024  Batches: 1  Memory Usage: 4kB
-> Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92 loops=1)
       Filter: indisunique
```

Note that Postgres Pro added a new field to the output to show planning time.

Postgres Professional, Moscow, Russia

## F.6. bloom

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

### F.6.1. Parameters

A bloom index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 – col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

### F.6.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
SELECT
  (random() * 1000000)::int as i1,
  (random() * 1000000)::int as i2,
  (random() * 1000000)::int as i3,
  (random() * 1000000)::int as i4,
  (random() * 1000000)::int as i5,
  (random() * 1000000)::int as i6
FROM
  generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
```

-----

```
Seq Scan on tbloom  (cost=0.00..2137.14 rows=3 width=24) (actual time=18.372..18.373
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.400 ms
Execution Time: 18.397 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
-----
3992 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
```

---

```
Seq Scan on tbloom  (cost=0.00..2137.00 rows=2 width=24) (actual time=11.880..11.881
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.154 ms
Execution Time: 11.896 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
-----
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN
```

---

```
Bitmap Heap Scan on tbloom  (cost=1792.00..1799.69 rows=2 width=24) (actual
time=0.388..0.388 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 25
  Heap Blocks: exact=22
-> Bitmap Index Scan on bloomidx  (cost=0.00..1792.00 rows=2 width=0) (actual
time=0.358..0.358 rows=25 loops=1)
  Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.118 ms
Execution Time: 0.412 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
```

```
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN
```

```
-----
Bitmap Heap Scan on tbloom  (cost=24.34..32.03 rows=2 width=24) (actual
time=0.036..0.037 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
  -> BitmapAnd  (cost=24.34..24.34 rows=2 width=0) (actual time=0.033..0.034 rows=0
loops=1)
    -> Bitmap Index Scan on btreeidx5  (cost=0.00..12.04 rows=500 width=0)
(actual time=0.032..0.032 rows=0 loops=1)
      Index Cond: (i5 = 123451)
    -> Bitmap Index Scan on btreeidx2  (cost=0.00..12.04 rows=500 width=0) (never
executed)
      Index Cond: (i2 = 898732)
Planning Time: 0.531 ms
Execution Time: 0.072 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

### F.6.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

### F.6.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

## F.7. btree\_gin

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

### F.7.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

### F.7.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/oddmuse/index.cgi/Gin> for additional information.

## F.8. btree\_gist

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` ("not equals"). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

### F.8.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (  
    cage    INTEGER,  
    animal TEXT,  
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)  
);  
  
=> INSERT INTO zoo VALUES(123, 'zebra');  
INSERT 0 1  
=> INSERT INTO zoo VALUES(123, 'zebra');  
INSERT 0 1  
=> INSERT INTO zoo VALUES(123, 'lion');  
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"  
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,  
    animal)=(123, zebra).  
=> INSERT INTO zoo VALUES(124, 'lion');  
INSERT 0 1
```

## F.8.2. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<janko-richter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information.

## F.9. citext

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

### F.9.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

### F.9.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT    NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry',  sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Tom',    sha256(random()::text::bytea) );  
INSERT INTO users VALUES ( 'Damian',  sha256(random()::text::bytea) );
```

```
INSERT INTO users VALUES ( 'NEAL',    sha256(random()::text::bytea) );
INSERT INTO users VALUES ( 'Bjørn',    sha256(random()::text::bytea) );

SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

### F.9.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the `regexp` functions, if you want to match case-sensitively, you can specify the “`c`” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

### F.9.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. It is, however, slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive

comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.

- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.

### F.9.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

## F.10. cube

This module implements a data type `cube` for representing multidimensional cubes.

### F.10.1. Syntax

Table F.6 shows the valid external representations for the `cube` type.  $x$ ,  $y$ , etc. denote floating-point numbers.

**Table F.6. Cube External Representations**

| External Syntax                            | Meaning                                                                                               |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------|
| $x$                                        | A one-dimensional point (or, zero-length one-dimensional interval)                                    |
| $( x )$                                    | Same as above                                                                                         |
| $x1, x2, \dots, xn$                        | A point in $n$ -dimensional space, represented internally as a zero-volume cube                       |
| $( x1, x2, \dots, xn )$                    | Same as above                                                                                         |
| $( x ), ( y )$                             | A one-dimensional interval starting at $x$ and ending at $y$ or vice versa; the order does not matter |
| $[ ( x ), ( y ) ]$                         | Same as above                                                                                         |
| $( x1, \dots, xn ), ( y1, \dots, yn )$     | An $n$ -dimensional cube represented by a pair of its diagonally opposite corners                     |
| $[ ( x1, \dots, xn ), ( y1, \dots, yn ) ]$ | Same as above                                                                                         |

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so  $[(x), (y)]$  is the same as  $[ ( x ), ( y ) ]$ .

### F.10.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

### F.10.3. Usage

Table F.7 shows the operators provided for type `cube`.

**Table F.7. Cube Operators**

| Operator | Result  | Description                          |
|----------|---------|--------------------------------------|
| $a = b$  | boolean | The cubes $a$ and $b$ are identical. |

| Operator                    | Result  | Description                                                                                                                                                                                                                                                                                   |
|-----------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>a &amp;&amp; b</code> | boolean | The cubes a and b overlap.                                                                                                                                                                                                                                                                    |
| <code>a @&gt; b</code>      | boolean | The cube a contains the cube b.                                                                                                                                                                                                                                                               |
| <code>a &lt;@ b</code>      | boolean | The cube a is contained in the cube b.                                                                                                                                                                                                                                                        |
| <code>a &lt; b</code>       | boolean | The cube a is less than the cube b.                                                                                                                                                                                                                                                           |
| <code>a &lt;= b</code>      | boolean | The cube a is less than or equal to the cube b.                                                                                                                                                                                                                                               |
| <code>a &gt; b</code>       | boolean | The cube a is greater than the cube b.                                                                                                                                                                                                                                                        |
| <code>a &gt;= b</code>      | boolean | The cube a is greater than or equal to the cube b.                                                                                                                                                                                                                                            |
| <code>a &lt;&gt; b</code>   | boolean | The cube a is not equal to the cube b.                                                                                                                                                                                                                                                        |
| <code>a -&gt; n</code>      | float8  | Get $n$ -th coordinate of cube (counting from 1).                                                                                                                                                                                                                                             |
| <code>a ~&gt; n</code>      | float8  | Get $n$ -th coordinate of cube in following way: $n = 2 * k - 1$ means lower bound of $k$ -th dimension, $n = 2 * k$ means upper bound of $k$ -th dimension. Negative $n$ denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support. |
| <code>a &lt;-&gt; b</code>  | float8  | Euclidean distance between a and b.                                                                                                                                                                                                                                                           |
| <code>a &lt;#&gt; b</code>  | float8  | Taxicab (L-1 metric) distance between a and b.                                                                                                                                                                                                                                                |
| <code>a &lt;=&gt; b</code>  | float8  | Chebyshev (L-inf metric) distance between a and b.                                                                                                                                                                                                                                            |

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The scalar ordering operators (`<`, `>=`, etc) do not make a lot of sense for any practical purpose but sorting. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a `UNIQUE` constraint on a `cube` column.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

Table F.8 shows the available functions.

**Table F.8. Cube Functions**

| Function                                  | Result  | Description                                                                                                                                                                                            | Example                                                              |
|-------------------------------------------|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| <code>cube(float8)</code>                 | cube    | Makes a one dimensional cube with both coordinates the same.                                                                                                                                           | <code>cube(1) == '(1)'</code>                                        |
| <code>cube(float8, float8)</code>         | cube    | Makes a one dimensional cube.                                                                                                                                                                          | <code>cube(1,2) == '(1), (2)'</code>                                 |
| <code>cube(float8[])</code>               | cube    | Makes a zero-volume cube using the coordinates defined by the array.                                                                                                                                   | <code>cube(ARRAY[1,2]) == '(1,2)'</code>                             |
| <code>cube(float8[], float8[])</code>     | cube    | Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.                                                                               | <code>cube(ARRAY[1,2], ARRAY[3,4]) == '(1,2), (3,4)'</code>          |
| <code>cube(cube, float8)</code>           | cube    | Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values. | <code>cube('(1,2), (3,4)')::cube, 5) == '(1,2,5), (3,4,5)'</code>    |
| <code>cube(cube, float8, float8)</code>   | cube    | Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.                                                                | <code>cube('(1,2), (3,4)')::cube, 5, 6) == '(1,2,5), (3,4,6)'</code> |
| <code>cube_dim(cube)</code>               | integer | Returns the number of dimensions of the cube.                                                                                                                                                          | <code>cube_dim('(1,2), (3,4)') == '2'</code>                         |
| <code>cube_ll_coord(cube, integer)</code> | float8  | Returns the <i>n</i> -th coordinate value for the lower left corner of the cube.                                                                                                                       | <code>cube_ll_coord('(1,2), (3,4)', 2) == '2'</code>                 |
| <code>cube_ur_coord(cube, integer)</code> | float8  | Returns the <i>n</i> -th coordinate value for the upper right corner of the cube.                                                                                                                      | <code>cube_ur_coord('(1,2), (3,4)', 2) == '4'</code>                 |
| <code>cube_is_point(cube)</code>          | boolean | Returns true if the cube is a point, that is, the two defining corners are the same.                                                                                                                   |                                                                      |
| <code>cube_distance(cube, cube)</code>    | float8  | Returns the distance between two cubes. If both cubes are points, this                                                                                                                                 |                                                                      |

| Function                                             | Result | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Example                                                                                                                                                                                   |
|------------------------------------------------------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                      |        | is the normal distance function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                           |
| <code>cube_subset(cube, integer[])</code>            | cube   | Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the end-points of a single dimension, or to drop dimensions, or to reorder them as desired.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <code>cube_subset(cube(' (1, 3, 5), (6, 7, 8) '), ARRAY[2]) == ' (3), (7) '       cube_subset(cube(' (1, 3, 5), (6, 7, 8) '), ARRAY[3, 2, 1, 1]) == ' (5, 3, 1, 1), (8, 7, 6, 6) '</code> |
| <code>cube_union(cube, cube)</code>                  | cube   | Produces the union of two cubes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                           |
| <code>cube_inter(cube, cube)</code>                  | cube   | Produces the intersection of two cubes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                                                                                                                           |
| <code>cube_enlarge(cube, r double, n integer)</code> | cube   | Increases the size of the cube by the specified radius $r$ in at least $n$ dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius $r$ . Lower-left coordinates are decreased by $r$ and upper-right coordinates are increased by $r$ . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$ ) then both coordinates are set to their average. If $n$ is greater than the number of defined dimensions and the cube is being enlarged ( $r > 0$ ), then extra dimensions are added to make $n$ altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points. | <code>cube_enlarge(' (1, 2), (3, 4) ', 0.5, 3) == ' (0.5, 1.5, -0.5), (3.5, 4.5, 0.5) '</code>                                                                                            |

#### F.10.4. Defaults

I believe this union:

```
select cube_union(' (0, 5, 2), (2, 3, 1) ', '0');
```

```
cube_union
-----
(0, 0, 0), (2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1), (1,1)', '(-2), (2)');
cube_inter
-----
(0, 0), (1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2), (2,3,1)', '(0,0,0), (0,0,0)');
cube_inter('(0,-1), (1,1)', '(-2,0), (2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0), (1,1)', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

## F.10.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

## F.10.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

## F.11. dblink

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

See also [postgres\\_fdw](#), which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

## dblink\_connect

`dblink_connect` — opens a persistent connection to a remote database

### Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

### Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

### Arguments

*connname*

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

*connstr*

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 35.1.1](#). Alternatively, the name of a foreign server.

### Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

### Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

### Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
      OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```

dblink_connect
-----
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
properly
--      Otherwise, you will receive the following error from dblink_connect():
--      -----
--      ERROR:  password is required
--      DETAIL:  Non-superuser cannot connect if the server does not request a
password.
--      HINT:   Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
    dbname 'contrib_regression');

```

## **dblink\_connect\_u**

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

### **Synopsis**

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

### **Description**

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

## dblink\_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

### Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

### Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

### Arguments

*connname*

The name of a named connection to be closed.

### Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

### Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
OK
(1 row)
```

## dblink

`dblink` — executes a query in a remote database

## Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

## Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

## Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select pronomame, prosrc from pg_proc')
AS t1(pronomame name, prosrc text)
WHERE pronomame LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `pronomame` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

## Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

## Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
 proname | prosrc
```

```

## dblink\_exec

`dblink_exec` — executes a command in a remote database

### Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

### Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

### Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*connstr*

A connection info string, as previously described for `dblink_connect`.

*sql*

The SQL command that you wish to execute in the remote database, for example `insert into foo values (0, 'a', '{"a0","b0","c0"}')`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

### Return Value

Returns status, either the command's status string or `ERROR`.

### Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
dblink_connect
-----
OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
dblink_exec
-----
INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
dblink_connect
```

```
-----
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}'');');
      dblink_exec
-----

INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

      dblink_exec
-----

ERROR
(1 row)
```

## dblink\_open

`dblink_open` — opens a cursor in a remote database

## Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

## Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name to assign to this cursor.

*sql*

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either `OK` or `ERROR`.

## Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
-----
OK
(1 row)
```

## dblink\_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

## Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
  returns setof record
```

## Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to fetch from.

*howmany*

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

## Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteain  | byteain
 byteale  | byteale
 bytealike| bytealike
 bytealt  | bytealt
 byteane  | byteane
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteanlike| byteanlike
 byteaout  | byteaout
(2 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
(0 rows)
```

## dblink\_close

`dblink_close` — closes a cursor in a remote database

## Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

## Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

## Arguments

*connname*

Name of the connection to use; omit this parameter to use the unnamed connection.

*cursorname*

The name of the cursor to close.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

## Return Value

Returns status, either `OK` or `ERROR`.

## Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

## Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
-----
 OK
(1 row)
```

## **dblink\_get\_connections**

`dblink_get_connections` — returns the names of all open named dblink connections

### **Synopsis**

```
dblink_get_connections() returns text[]
```

### **Description**

`dblink_get_connections` returns an array of the names of all open named dblink connections.

### **Return Value**

Returns a text array of connection names, or NULL if none.

### **Examples**

```
SELECT dblink_get_connections();
```

## **dblink\_error\_message**

`dblink_error_message` — gets last error message on the named connection

### **Synopsis**

`dblink_error_message(text connname)` returns text

### **Description**

`dblink_error_message` fetches the most recent remote error message for a given connection.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns last error message, or OK if there has been no error in this connection.

### **Notes**

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

### **Examples**

```
SELECT dblink_error_message('dtest1');
```

## **dblink\_send\_query**

`dblink_send_query` — sends an async query to a remote database

### **Synopsis**

```
dblink_send_query(text connname, text sql) returns int
```

### **Description**

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

### **Arguments**

*connname*

Name of the connection to use.

*sql*

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

### **Return Value**

Returns 1 if the query was successfully dispatched, 0 otherwise.

### **Examples**

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

## **dblink\_is\_busy**

`dblink_is_busy` — checks if connection is busy with an async query

### **Synopsis**

```
dblink_is_busy(text connname) returns int
```

### **Description**

`dblink_is_busy` tests whether an async query is in progress.

### **Arguments**

*connname*

Name of the connection to check.

### **Return Value**

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

### **Examples**

```
SELECT dblink_is_busy('dtest1');
```

## dblink\_get\_notify

dblink\_get\_notify — retrieve async notifications on a connection

### Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

### Description

dblink\_get\_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink\_exec. For details see [LISTEN](#) and [NOTIFY](#).

### Arguments

*connname*

The name of a named connection to get notifications on.

### Return Value

Returns setof (notify\_name text, be\_pid int, extra text), or an empty set if none.

### Examples

```
SELECT dblink_exec('LISTEN virtual');
       dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
 notify_name | be_pid | extra
-----+-----+-----
virtual     |    1229 |
(1 row)
```

## dblink\_get\_result

`dblink_get_result` — gets an async query result

## Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

## Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

## Arguments

*connname*

Name of the connection to use.

*fail\_on\_error*

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

## Return Value

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

## Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

## Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
t1;
t1
----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 |      f3
----+-----+-----
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 | f3
----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
select * from foo where f1 > 6') AS t1;
```

```
 t1
----
  1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 |      f3
----+-----+-----
  0 | a  | {a0,b0,c0}
  1 | b  | {a1,b1,c1}
  2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 |      f3
----+-----+-----
  7 | h  | {a7,b7,c7}
  8 | i  | {a8,b8,c8}
  9 | j  | {a9,b9,c9}
 10 | k  | {a10,b10,c10}
(4 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
 f1 | f2 | f3
----+-----+-----
(0 rows)
```

## **dblink\_cancel\_query**

`dblink_cancel_query` — cancels any active query on the named connection

### **Synopsis**

```
dblink_cancel_query(text connname) returns text
```

### **Description**

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

### **Arguments**

*connname*

Name of the connection to use.

### **Return Value**

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

### **Examples**

```
SELECT dblink_cancel_query('dtest1');
```

## dblink\_get\_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

### Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

### Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

### Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

### Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
position | colname  
-----+-----  
1 | f1  
2 | f2  
3 | f3  
(3 rows)
```

## dblink\_build\_sql\_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');  
       dblink_build_sql_insert
```

-----

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b' 'a','1')
(1 row)
```

## dblink\_build\_sql\_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

### Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

## dblink\_build\_sql\_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

### Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

### Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

### Arguments

*relname*

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

*primary\_key\_attnums*

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

*num\_primary\_key\_atts*

The number of primary key fields.

*src\_pk\_att\_vals\_array*

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

*tgt\_pk\_att\_vals\_array*

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

### Return Value

Returns the requested SQL statement as text.

### Notes

As of PostgreSQL 9.0, the attribute numbers in *primary\_key\_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

### Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');  
       dblink_build_sql_update  
-----  
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
```

(1 row)

## F.12. dict\_int

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

### F.12.1. Configuration

The dictionary accepts two options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.

### F.12.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
 ts_lexize
-----
 {123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

## F.13. dict\_xsyn

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

### F.13.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.
- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:  

```
word syn1 syn2 syn3
```
- The sharp (#) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$SHAREDIR/tsearch_data/`, for an example.

## F.13.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
        ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
        ts_lexize
-----
{word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
        ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
        ts_lexize
-----
{word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

## F.14. dump\_stat

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

### F.14.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

### F.14.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (  
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]  
  WHERE starelid = t_relname::regclass  
    AND to_attnum(t_relname, staattnum) = t_attnum  
    AND to_atttype(t_relname, staattnum) = t_atttype  
    AND stainherit = t_stainherit  
  RETURNING *)  
ins as (  
  SELECT expression [, ...]  
  WHERE NOT EXISTS (SELECT * FROM upsert)  
    AND to_attnum(t_relname, t_attnum) IS NOT NULL  
    AND to_atttype(t_relname, t_attnum) = t_atttype)  
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where *expression* can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)  
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the *dbname* database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that contains statistical data for the specified `relation`.

`to_schema_qualified_operator(opid oid)` returns `text`

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator');
           to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns `text`

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns `text`

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray)` returns `oid`

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
           anyarray_elemtype
-----
                        23
(1 row)
```

`to_attname(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text)` returns `int2`

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text)` returns `text`

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text)` returns `oid`

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid)` returns `oid`

`get_namespace` returns the schema of the given relation as `oid`.

## F.15. earthdistance

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

### Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

## F.15.1. Cube-based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the x, y, and z distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.9](#).

**Table F.9. Cube-based Earthdistance Functions**

| Function                                 | Returns             | Description                                                                                                                                   |
|------------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>earth()</code>                     | <code>float8</code> | Returns the assumed radius of the Earth.                                                                                                      |
| <code>sec_to_gc(float8)</code>           | <code>float8</code> | Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them. |
| <code>gc_to_sec(float8)</code>           | <code>float8</code> | Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them. |
| <code>ll_to_earth(float8, float8)</code> | <code>earth</code>  | Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.            |

| Function                                  | Returns             | Description                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>latitude(earth)</code>              | <code>float8</code> | Returns the latitude in degrees of a point on the surface of the Earth.                                                                                                                                                                                                                                                                     |
| <code>longitude(earth)</code>             | <code>float8</code> | Returns the longitude in degrees of a point on the surface of the Earth.                                                                                                                                                                                                                                                                    |
| <code>earth_distance(earth, earth)</code> | <code>float8</code> | Returns the great circle distance between two points on the surface of the Earth.                                                                                                                                                                                                                                                           |
| <code>earth_box(earth, float8)</code>     | <code>cube</code>   | Returns a box suitable for an indexed search using the <code>cube @&gt;</code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query. |

## F.15.2. Point-based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.10](#).

**Table F.10. Point-based Earthdistance Operators**

| Operator                           | Returns             | Description                                                                    |
|------------------------------------|---------------------|--------------------------------------------------------------------------------|
| <code>point &lt;@&gt; point</code> | <code>float8</code> | Gives the distance in statute miles between two points on the Earth's surface. |

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

## F.16. fasttrun

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

### F.16.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

## F.16.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
    loop
      PERFORM fasttruncate('tt1');
    end loop;
end;
$$ language plpgsql;
```

## F.16.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.17. file\_fdw

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the data null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in `COPY`'s `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in `COPY`'s `FORCE_NULL` option.

`COPY`'s `oids` and `FORCE_QUOTE` options are currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the default role `pg_read_server_files` (to use a filename) or the default role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

### Example F.1. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,
```

```
transaction_id bigint,  
error_severity text,  
sql_state_code text,  
message text,  
detail text,  
hint text,  
internal_query text,  
internal_query_pos integer,  
context text,  
query text,  
query_pos integer,  
location text,  
application_name text  
) SERVER pglog  
OPTIONS ( filename '/home/josh/data/log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

## F.18. fulleq

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

### F.18.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

### F.18.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`

- `inet`
- `cidr`
- `varchar`
- `date`
- `time`
- `timestamp`
- `timestampz`
- `interval`
- `timetz`

### F.18.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.19. fuzzystmatch

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

### Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8).

### F.19.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text  
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');  
  
SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');  
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');  
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');  
  
CREATE TABLE s (nm text);  
  
INSERT INTO s VALUES ('john');  
INSERT INTO s VALUES ('joan');  
INSERT INTO s VALUES ('wobbly');  
INSERT INTO s VALUES ('jack');
```

```
SELECT * FROM s WHERE soundex(nm) = soundex('john');
```

```
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

## F.19.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns  
int
```

```
levenshtein(text source, text target) returns int
```

```
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int  
sub_cost, int max_d) returns int
```

```
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');  
levenshtein
```

```
-----  
                2  
(1 row)
```

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);  
levenshtein
```

```
-----  
                3  
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);  
levenshtein_less_equal
```

```
-----  
                3  
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);  
levenshtein_less_equal
```

```
-----  
                4  
(1 row)
```

## F.19.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
metaphone
-----
KM
(1 row)
```

## F.19.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
dmetaphone
-----
KMP
(1 row)
```

## F.20. hstore

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

### F.20.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more `key => value` pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2':hstore;
hstore
-----
"a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “NULL”.

### Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters

and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

## F.20.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in [Table F.11](#), the functions in [Table F.12](#).

**Table F.11. hstore Operators**

| Operator                          | Description                                               | Example                                                                       | Result                                             |
|-----------------------------------|-----------------------------------------------------------|-------------------------------------------------------------------------------|----------------------------------------------------|
| <code>hstore -&gt; text</code>    | get value for key (NULL if not present)                   | <code>'a=&gt;x, b=&gt;y'::hstore -&gt; 'a'</code>                             | <code>x</code>                                     |
| <code>hstore -&gt; text[]</code>  | get values for keys (NULL if not present)                 | <code>'a=&gt;x, b=&gt;y, c=&gt;z'::hstore -&gt; ARRAY['c', 'a']</code>        | <code>{"z", "x"}</code>                            |
| <code>hstore    hstore</code>     | concatenate hstores                                       | <code>'a=&gt;b, c=&gt;d'::hstore    'c=&gt;x, d=&gt;q'::hstore</code>         | <code>"a"=&gt;"b", "c"=&gt;"x", "d"=&gt;"q"</code> |
| <code>hstore ? text</code>        | does hstore contain key?                                  | <code>'a=&gt;1'::hstore ? 'a'</code>                                          | <code>t</code>                                     |
| <code>hstore ?&amp; text[]</code> | does hstore contain all specified keys?                   | <code>'a=&gt;1, b=&gt;2'::hstore ?&amp; ARRAY['a', 'b']</code>                | <code>t</code>                                     |
| <code>hstore ?  text[]</code>     | does hstore contain any of the specified keys?            | <code>'a=&gt;1, b=&gt;2'::hstore ?  ARRAY['b', 'c']</code>                    | <code>t</code>                                     |
| <code>hstore @&gt; hstore</code>  | does left operand contain right?                          | <code>'a=&gt;b, c=&gt;NULL'::hstore @&gt; 'b=&gt;1'</code>                    | <code>t</code>                                     |
| <code>hstore &lt;@ hstore</code>  | is left operand contained in right?                       | <code>'a=&gt;c'::hstore &lt;@ 'a=&gt;b, b=&gt;1, c=&gt;NULL'</code>           | <code>f</code>                                     |
| <code>hstore - text</code>        | delete key from left operand                              | <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'b'::text</code>                  | <code>"a"=&gt;"1", "c"=&gt;"3"</code>              |
| <code>hstore - text[]</code>      | delete keys from left operand                             | <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - ARRAY['a', 'b']</code>            | <code>"c"=&gt;"3"</code>                           |
| <code>hstore - hstore</code>      | delete matching pairs from left operand                   | <code>'a=&gt;1, b=&gt;2, c=&gt;3'::hstore - 'a=&gt;4, b=&gt;2'::hstore</code> | <code>"a"=&gt;"1", "c"=&gt;"3"</code>              |
| <code>record #= hstore</code>     | replace fields in record with matching values from hstore | see Examples section                                                          |                                                    |
| <code>%% hstore</code>            | convert hstore to array of alternating keys and values    | <code>%% 'a=&gt;foo, b=&gt;bar'::hstore</code>                                | <code>{a,foo,b,bar}</code>                         |
| <code>%# hstore</code>            | convert hstore to two-dimensional key/value array         | <code>%# 'a=&gt;foo, b=&gt;bar'::hstore</code>                                | <code>{{a,foo},{b,bar}}</code>                     |

**Note**

Prior to PostgreSQL 8.2, the containment operators @> and <@ were called @ and ~, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

**Table F.12. hstore Functions**

| Function                 | Return Type | Description                                                                                          | Example                                                                                | Result                                                                                          |
|--------------------------|-------------|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| hstore(record)           | hstore      | construct an hstore from a record or row                                                             | hstore(ROW(1, 2))                                                                      | f1=>1, f2=>2                                                                                    |
| hstore(text[])           | hstore      | construct an hstore from an array, which may be either a key/value array, or a two-dimensional array | hstore(ARRAY['a', '1', 'b', '2'])    hstore(ARRAY[['c', '3'], ['d', '4']])             | a=>1, b=>2, c=>3, d=>4                                                                          |
| hstore(text[], text[])   | hstore      | construct an hstore from separate key and value arrays                                               | hstore(ARRAY['a', 'b'], ARRAY['1', '2'])                                               | "a"=>"1", "b"=>"2"                                                                              |
| hstore(text, text)       | hstore      | make single-item hstore                                                                              | hstore('a', 'b')                                                                       | "a"=>"b"                                                                                        |
| akeys(hstore)            | text[]      | get hstore's keys as an array                                                                        | akeys('a=>1, b=>2')                                                                    | {a,b}                                                                                           |
| skeys(hstore)            | setof text  | get hstore's keys as a set                                                                           | skeys('a=>1, b=>2')                                                                    | a<br>b                                                                                          |
| avals(hstore)            | text[]      | get hstore's values as an array                                                                      | avals('a=>1, b=>2')                                                                    | {1,2}                                                                                           |
| svals(hstore)            | setof text  | get hstore's values as a set                                                                         | svals('a=>1, b=>2')                                                                    | 1<br>2                                                                                          |
| hstore_to_array(hstore)  | text[]      | get hstore's keys and values as an array of alternating keys and values                              | hstore_to_array('a=>1, b=>2')                                                          | {a,1,b,2}                                                                                       |
| hstore_to_matrix(hstore) | text[]      | get hstore's keys and values as a two-dimensional array                                              | hstore_to_matrix('a=>1, b=>2')                                                         | {{a,1},{b,2}}                                                                                   |
| hstore_to_json(hstore)   | json        | get hstore as a json value, converting all non-null values to JSON strings                           | hstore_to_json('a key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4')  | {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"} |
| hstore_to_jsonb(hstore)  | jsonb       | get hstore as a jsonb value, converting all non-                                                     | hstore_to_jsonb('a key=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') | {"a key": "1", "b": "t", "c": null,                                                             |

| each(hstore)                    | setof(key text, value text) | get hstore's keys and values as a set                                                                                 | <pre> select from each( 'a=&gt;1,b=&gt;2') </pre>                                                                                | <pre> key   value -----+----- a     1 b     2 </pre>                                                        |
| exist(hstore, text)             | boolean                     | does hstore contain key?                                                                                              | <pre> exist('a=&gt;1', 'a') </pre>                                                                                               | t                                                                                                           |
| defined(hstore, text)           | boolean                     | does hstore contain non-NULL value for key?                                                                           | <pre> defined( 'a=NULL', 'a') </pre>                                                                                             | f                                                                                                           |
| delete(hstore, text)            | hstore                      | delete pair with matching key                                                                                         | <pre> delete('a=&gt;1, b=&gt;2', 'b') </pre>                                                                                     | "a"=>"1"                                                                                                    |
| delete(hstore, text[])          | hstore                      | delete pairs with matching keys                                                                                       | <pre> delete('a=&gt;1, b=&gt;2,c=&gt;3', ARRAY['a','b']) </pre>                                                                  | "c"=>"3"                                                                                                    |
| delete(hstore, hstore)          | hstore                      | delete pairs matching those in the second argument                                                                    | <pre> delete('a=&gt;1, b=&gt;2', 'a=&gt;4, b=&gt;2':hstore) </pre>                                                               | "a"=>"1"                                                                                                    |
| populate_record(record, hstore) | record                      | replace fields in record with matching values from hstore                                                             | see Examples section                                                                                                             |                                                                                                             |

**Note**

The function `hstore_to_json` is used when an `hstore` value is cast to `json`. Likewise, `hstore_to_jsonb` is used when an `hstore` value is cast to `jsonb`.

**Note**

The function `populate_record` is actually declared with `anyelement`, not `record`, as its first argument, but it will reject non-record types with a run-time error.

**F.20.3. Indexes**

`hstore` has GiST and GIN index support for the `@>`, `?`, `?&` and `?|` operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`hstore` also supports `btree` or `hash` indexes for the `=` operator. This allows `hstore` columns to be declared `UNIQUE`, or to be used in `GROUP BY`, `ORDER BY` or `DISTINCT` expressions. The sort ordering for `hstore` values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for `=` comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```
CREATE INDEX hidx ON testhstore USING HASH (h);
```

**F.20.4. Examples**

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || hstore('c', '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
```

```
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an `hstore` to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
```

```
SELECT * FROM populate_record(null::test,
                               '"col1"=>"456", "col2"=>"zzz"');
```

```
col1 | col2 | col3
-----+-----+-----
456  | zzz  |
```

```
(1 row)
```

Modify an existing record using the values from an `hstore`:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

## F.20.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
  (SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
  key      | count
-----+-----
line       |    883
query      |    207
pos        |    203
node       |    202
space      |    197
status     |    195
public     |    194
title      |    190
org        |    189
.....
```

## F.20.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

## F.20.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperl_u`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extensions for PL/Python are called `hstore_plpythonu`, `hstore_plpython2u`, and `hstore_plpython3u` (see [Section 47.1](#) for the PL/Python naming convention). If you use them, `hstore` values are mapped to Python dictionaries.

### Caution

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

## F.20.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

Teodor Sigaev <teodor@sigaev.ru>, Moscow, Delta-Soft Ltd., Russia

Additional enhancements by Andrew Gierth <andrew@tao11.riddles.org.uk>, United Kingdom

## F.21. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

**Table F.13. Modules**

| Language         | Extension name              | Dictionary name               | Configuration name            |
|------------------|-----------------------------|-------------------------------|-------------------------------|
| American English | <code>hunspell_en_us</code> | <code>english_hunspell</code> | <code>english_hunspell</code> |
| Dutch            | <code>hunspell_nl_nl</code> | <code>dutch_hunspell</code>   | <code>dutch_hunspell</code>   |
| French           | <code>hunspell_fr</code>    | <code>french_hunspell</code>  | <code>french_hunspell</code>  |
| Russian          | <code>hunspell_ru_ru</code> | <code>russian_hunspell</code> | <code>russian_hunspell</code> |

### F.21.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias  | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----
+-----+-----+-----+-----
  asciiword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
  english_hunspell | {ability}
```

(1 row)

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (  
    COPY = simple  
);  
  
ALTER TEXT SEARCH CONFIGURATION russian_en  
    ALTER MAPPING FOR asciiword, asciihword, hword_asciipart  
    WITH english_hunspell, english_stem;  
  
ALTER TEXT SEARCH CONFIGURATION russian_en  
    ALTER MAPPING FOR word, hword, hword_part  
    WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');  
           to_tsvector  
-----  
'animal':7 'blue':2 'large':6 'whale':3  
(1 row)
```

Search query might look like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')  
       @@ to_tsquery('english_hunspell', 'large & whale');  
       ?column?  
-----  
t  
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);  
INSERT INTO table1 VALUES ('The blue whale is the largest animal');  
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)  
       @@ to_tsquery('english_hunspell', 'blue & animal');  
           t  
-----  
The blue whale is the largest animal  
(1 row)
```

## F.22. in\_memory

The `in_memory` extension enables you to store data in Postgres Pro shared memory using in-memory tables implemented via foreign data wrappers (FDW).

### Note

This extension cannot be used together with prepared transactions or while built-in connection pooling is enabled.

In-memory tables are *index-organized* — table rows are stored in leaf pages of the B-tree index defined on the primary key for the table. This solution offers the following benefits:

- Fast random access on the primary key. This can result in significant performance benefits when working with data that requires a very high read and write access rate, especially on multi-core systems.
- Effective space usage. There is no primary key duplication as all data is stored directly in the index.

In-memory tables support transactions, including savepoints. However, the data in such tables is stored only while the server is running. Once the server is shut down, all in-memory data gets truncated. When using in-memory tables, you should also take into account the following restrictions:

- Persistence, WAL, and data replication are currently not supported for in-memory tables.
- Secondary indexes are not supported.
- Isolation levels are supported up to `REPEATABLE READ`. `SERIALIZABLE` isolation level is not supported. `REPEATABLE READ` level is used instead.
- In-memory tables do not support TOAST or any other mechanism for storing big tuples. Since the in-memory page size is 1 kB, and the B-tree index requires at least three tuples in a page, the maximum row length is limited to 304 bytes.
- When a row is deleted from an in-memory table, the corresponding data page is not freed. See [Section F.22.2.3](#) for details.

## F.22.1. Installation and Setup

To enable in-memory tables for your cluster:

1. Make sure that the [postgres\\_fdw](#) module is enabled.
2. Add the `in_memory` value to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'in_memory'
```

3. Create the `in_memory` extension using the following statement:

```
CREATE EXTENSION in_memory;
```

As a result, the `in_memory` foreign server is created, and a separate shared memory pool is allocated for in-memory tables, with pre-created pages for storing in-memory data. For in-memory tables, smaller locality is required for effective memory access, as compared to hard drives or SSD, so in-memory page size is 1 kB only. Once the extension is created, you can start using in-memory tables as explained in [Section F.22.2](#).

### Tip

If required, you can increase the memory size allocated for in-memory tables. For details, see [Section F.22.2.6](#).

## F.22.2. Usage

### F.22.2.1. Creating In-Memory Tables

To add an in-memory table to your database, create a foreign table on the `in_memory` server, using the regular [CREATE FOREIGN TABLE](#) syntax. By default, a unique B-tree index is built upon the first column, in the ascending order. If required, you can use the `INDICES` option in the `OPTIONS` clause to define a different B-tree index structure, as follows:

```
OPTIONS ( INDICES '[ UNIQUE ] {column [ COLLATE collation ] [ASC | DESC] } [, ... ]' )
```

where *column* is the column to include into the B-tree index, and *collation* is the name of the collation to use for this column. You can specify up to eight arbitrary columns separated by commas, with sorting

options defined for each of these columns (`COLLATE`, `ASC/DESC`). The `UNIQUE` declares the created index unique, reiterating the default behavior.

All columns to be used in the B-tree index must be of a type for which the default B-tree operator class is available. For details on operator classes, see [Section 11.10](#).

### Examples

Create an in-memory table `blog_views` to store statistics on blog views based on blog post IDs, with the unique B-tree index built upon the first column, in the ascending order:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
OPTIONS (INDICES 'UNIQUE (id)');
```

Define the B-tree index on the `id` and `author` columns, with the `author` values sorted in the ascending order using `"ru_RU"` collation:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory

```

## F.22.2.2. Running Queries on In-Memory Tables

Once an in-memory table is created, you can run all the main DML operations on this table: `SELECT`, `INSERT`, `UPDATE`, `DELETE`.

If you use the primary key as the scan qualifier when running queries, a key lookup or range scan is performed. Otherwise, a full index scan is required.

### Examples

Fill the `blog_views` table with initial zero values for initial ten blog posts:

```
postgres=# INSERT INTO blog_views (SELECT id, 0 FROM generate_series(1, 10) AS id);
```

Increment the view count for a couple of posts and display the result:

```
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 1
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 2
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 2;
UPDATE 1
postgres=# SELECT * FROM blog_views WHERE id = 1 OR id = 2;
 id | views
----+-----
  1 |    2
  2 |    1
(2 rows)
```

Check planning and execution costs for a query that only requires a primary key lookup:

```
postgres=# EXPLAIN ANALYZE SELECT * FROM blog_views WHERE id = 1;
```

## QUERY PLAN

```
-----
Foreign Scan on blog_views  (cost=0.02..0.03 rows=1 width=16)
(actual time=0.013..0.014 rows=1 loops=1)
  Pk conds: (id = 1)
Planning time: 0.060 ms
Execution time: 0.035 ms
(4 rows)
```

Check the costs of calculating the sum of all views, which requires a full index scan:

```
postgres=# EXPLAIN ANALYZE SELECT SUM(views) FROM blog_views;
               QUERY PLAN
```

```
-----
Aggregate  (cost=1.62..1.63 rows=1 width=32)
(actual time=0.323..0.323 rows=1 loops=1)
Foreign Scan on blog_views  (cost=0.02..1.30 rows=128 width=8)
(actual time=0.005..0.168 rows=1000 loops=1)
Planning time: 0.113 ms
Execution time: 0.353 ms
(4 rows)
```

### F.22.2.3. Deleting In-Memory Data

When a row is deleted from an in-memory table, data pages are not freed. To free the pages occupied by in-memory tables, you can:

- Delete the table using the `DROP FOREIGN TABLE` command.
- Truncate the table using the `TRUNCATE` command.

`RESTART IDENTITY`, `CONTINUE IDENTITY`, `CASCADE`, and `RESTRICT` options of the `TRUNCATE` command are not supported by in-memory tables.

### F.22.2.4. Writing Data to In-Memory Tables on Hot Standby

In some cases, it can be useful to perform write operations on hot standby servers. For example, suppose you need to collect statistics on queries run on hot standby. Since in-memory tables are writable, you can use them for such purposes.

To set up in-memory tables for write queries on standby, create the required in-memory tables on the master server as explained in [Section F.22.2.1](#). Once the replication is complete, you can start writing data to these tables on hot standby.

#### Important

If the hot standby server is restarted, all the data stored in its in-memory tables gets truncated. You can continue writing data to the same in-memory tables, but all the previously stored data will be lost.

### F.22.2.5. Getting Statistics on In-Memory Tables

To get statistics on in-memory pages available in your cluster, run the `in_memory_page_stats` function, which returns the number of all used and free in-memory pages, as well as the total number of pages allocated for in-memory tables. For example:

```
postgres=# SELECT * FROM in_memory.in_memory_page_stats();
 busy_pages | free_pages | all_pages
-----+-----+-----
        576 |       7616 |       8192
```

(1 row)

## F.22.2.6. Fine-Tuning Memory Settings

### F.22.2.6.1. Increasing Shared Memory Pool for In-Memory Tables

In-memory tables are stored in a separate shared memory segment. Its size is defined by the `in_memory.shared_pool_size` parameter. By default, this memory segment is limited to 8 MB.

If the data to be stored in in-memory tables exceeds the size of the allocated memory segment, the following error occurs:

```
ERROR: failed to get a new page: shared pool size is exceeded
```

To avoid such issues, you can increase the `in_memory.shared_pool_size` value, or limit the size of the stored data. Changing the shared pool size requires a server restart.

### F.22.2.6.2. Managing the Undo Log

To enable multi-version concurrency control (MVCC), the `in_memory` module uses the *undo log* — a shared-memory ring buffer that stores the previous versions of data entries and pages. The size of the undo log is defined by the `in_memory.undo_size` parameter and is limited to 1 MB by default. If a buffer overflow occurs before a transaction is complete, the following error is returned:

```
ERROR: failed to add undo record: undo size is exceeded
```

To avoid this issue, you can increase the `in_memory.undo_size` value, or split the transactions into smaller ones.

If the required version of the entry or page has already been overwritten in the undo log when it is accessed for read, the following error occurs:

```
ERROR: snapshot is outdated
```

In this case, you can:

- Increase the `in_memory.undo_size` value. Changing this parameter requires a server restart.
- Ensure that the undo log is not truncated while the snapshot is in use. To achieve this, you can use the `READ COMMITTED` isolation level, or split a complex query into several smaller ones.

## F.22.3. Reference

### F.22.3.1. Configuration Variables

`in_memory.shared_pool_size` (integer)

Defines the size of the shared memory segment allocated for in-memory tables.

Default: 8MB

`in_memory.undo_size` (integer)

Defines the size of the undo log.

Default: 1MB

### F.22.3.2. Functions

`in_memory.in_memory_page_stats()`

Displays statistics on pages of in-memory tables:

- `busy_pages` — in-memory pages containing any data.

- `free_pages` — empty in-memory pages. This number includes all the initially allocated pages to which no data has been written yet, as well as the pages from which all data has been deleted.
- `all_pages` — the total number of in-memory pages allocated on this server.

## F.22.4. Authors

Postgres Professional, Moscow, Russia

## F.23. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

### F.23.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

### F.23.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
SELECT left, int_array_aggregate(right) AS right
FROM one_to_many
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
  ( SELECT left, int_array_enum(right) AS right
    FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
      ON (summary.left = lefts.left)
  ) AS list
GROUP BY right
ORDER BY count DESC;
```

## F.24. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

### F.24.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.14](#), the operators in [Table F.15](#).

**Table F.14. intarray Functions**

| Function                                         | Return Type        | Description                                                              | Example                                           | Result       |
|--------------------------------------------------|--------------------|--------------------------------------------------------------------------|---------------------------------------------------|--------------|
| <code>icount(int[])</code>                       | <code>int</code>   | number of elements in array                                              | <code>icount('{1,2,3}'::int[])</code>             | 3            |
| <code>sort(int[], text dir)</code>               | <code>int[]</code> | sort array — <i>dir</i> must be <code>asc</code> or <code>desc</code>    | <code>sort('{1,2,3}'::int[], 'desc')</code>       | {3,2,1}      |
| <code>sort(int[])</code>                         | <code>int[]</code> | sort in ascending order                                                  | <code>sort(array[11, 77, 44])</code>              | {11, 44, 77} |
| <code>sort_asc(int[])</code>                     | <code>int[]</code> | sort in ascending order                                                  |                                                   |              |
| <code>sort_desc(int[])</code>                    | <code>int[]</code> | sort in descending order                                                 |                                                   |              |
| <code>uniq(int[])</code>                         | <code>int[]</code> | remove adjacent duplicates                                               | <code>uniq(sort('{1,2,3,2,1}'::int[]))</code>     | {1,2,3}      |
| <code>idx(int[], int item)</code>                | <code>int</code>   | index of first element matching <i>item</i> (0 if none)                  | <code>idx(array[11, 22, 33, 22, 11], 22)</code>   | 2            |
| <code>subarray(int[], int start, int len)</code> | <code>int[]</code> | portion of array starting at position <i>start</i> , <i>len</i> elements | <code>subarray('{1,2,3,2,1}'::int[], 2, 3)</code> | {2,3,2}      |
| <code>subarray(int[], int start)</code>          | <code>int[]</code> | portion of array starting at position <i>start</i>                       | <code>subarray('{1,2,3,2,1}'::int[], 2)</code>    | {2,3,2,1}    |
| <code>intset(int)</code>                         | <code>int[]</code> | make single-element array                                                | <code>intset(42)</code>                           | {42}         |

**Table F.15. intarray Operators**

| Operator                            | Returns            | Description                                                             |
|-------------------------------------|--------------------|-------------------------------------------------------------------------|
| <code>int[] &amp;&amp; int[]</code> | boolean            | overlap — <code>true</code> if arrays have at least one common element  |
| <code>int[] @&gt; int[]</code>      | boolean            | contains — <code>true</code> if left array contains right array         |
| <code>int[] &lt;@ int[]</code>      | boolean            | contained — <code>true</code> if left array is contained in right array |
| <code># int[]</code>                | int                | number of elements in array                                             |
| <code>int[] # int</code>            | int                | index (same as <code>idx</code> function)                               |
| <code>int[] + int</code>            | <code>int[]</code> | push element onto array (add it to end of array)                        |
| <code>int[] + int[]</code>          | <code>int[]</code> | array concatenation (right array added to the end of left one)          |
| <code>int[] - int</code>            | <code>int[]</code> | remove entries matching right argument from array                       |
| <code>int[] - int[]</code>          | <code>int[]</code> | remove elements of right array from left                                |
| <code>int[]   int</code>            | <code>int[]</code> | union of arguments                                                      |
| <code>int[]   int[]</code>          | <code>int[]</code> | union of arrays                                                         |
| <code>int[] &amp; int[]</code>      | <code>int[]</code> | intersection of arrays                                                  |
| <code>int[] @@ query_int</code>     | boolean            | <code>true</code> if array satisfies query (see below)                  |
| <code>query_int ~~ int[]</code>     | boolean            | <code>true</code> if array satisfies query (commutator of @@)           |

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1 & (2 | 3)` matches arrays that contain 1 and also contain either 2 or 3.

## F.24.2. Index Support

`intarray` provides index support for the `&&`, `@>`, `<@`, and `@@` operators, as well as regular array equality.

Two GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

### F.24.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__int_ops);

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

### F.24.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

## F.25. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

### F.25.1. Data Types

Table F.16 shows the data types provided by the `isn` module.

**Table F.16. isn Data Types**

| Data Type | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| EAN13     | European Article Numbers, always displayed in the EAN13 display format                |
| ISBN13    | International Standard Book Numbers to be displayed in the new EAN13 display format   |
| ISMN13    | International Standard Music Numbers to be displayed in the new EAN13 display format  |
| ISSN13    | International Standard Serial Numbers to be displayed in the new EAN13 display format |
| ISBN      | International Standard Book Numbers to be displayed in the old short display format   |
| ISMN      | International Standard Music Numbers to be displayed in the old short display format  |
| ISSN      | International Standard Serial Numbers to be displayed in the old short display format |
| UPC       | Universal Product Codes                                                               |

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

## F.25.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

## F.25.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.17](#). In this table, `isn` means any one of the module's data types.

**Table F.17. `isn` Functions**

| Function                       | Returns              | Description                                    |
|--------------------------------|----------------------|------------------------------------------------|
| <code>isn_weak(boolean)</code> | <code>boolean</code> | Sets the weak input mode (returns new setting) |
| <code>isn_weak()</code>        | <code>boolean</code> | Gets the current status of the weak mode       |

| Function                     | Returns              | Description                                           |
|------------------------------|----------------------|-------------------------------------------------------|
| <code>make_valid(isn)</code> | <code>isn</code>     | Validates an invalid number (clears the invalid flag) |
| <code>is_valid(isn)</code>   | <code>boolean</code> | Checks for the presence of the invalid flag           |

*Weak* mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the ! character at the end of the number.

Another special feature is that during input, you can write ? in place of the check digit, and the correct check digit will be inserted automatically.

## F.25.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

## F.25.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- [https://en.wikipedia.org/wiki/List\\_of\\_ISBN\\_identifier\\_groups](https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups)
- <https://www.isbn-international.org/content/isbn-users-manual>
- [https://en.wikipedia.org/wiki/International\\_Standard\\_Music\\_Number](https://en.wikipedia.org/wiki/International_Standard_Music_Number)
- <https://www.ismn-international.org/ranges.html>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

## F.25.6. Author

Germán Méndez Bravo (Kronuz), 2004 - 2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

## F.26. jquery

jQuery is a language to query `jsonb` data type. Its primary goal is to provide an additional functionality for `jsonb`, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a `jquery` data type (similar to `tsquery`) and the `@@` match operator for `jsonb`.

### F.26.1. Installation

Postgres Pro Enterprise distribution includes `jquery` as a contrib module. Once you complete Postgres Pro Enterprise installation, create the `jquery` extension, as follows:

```
CREATE EXTENSION jquery;
```

### F.26.2. JSON query language

jQuery extension contains `jquery` datatype which represents whole JSON query as a single value (like `tsquery` does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary\_operator value* or *path unary\_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - similar\_ids is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array similar\_product\_ids contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with jquery keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (AND, OR, NOT) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 2 and the `b` key is 2

- `%( $ >= 10 AND $ <= 20 )` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:( $ >= 0 AND $ <= 1 )
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:( $ >= 0 AND $ <= 1 ) )
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ( $ >= 0 AND $ <= 1 ) ) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:( $ IS OBJECT OR $ IS BOOLEAN )` - JSON is a structure of nested objects with booleans as leaf values.
- `#.%.#:( $ >= 0 AND $ <= 1 )` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.* = *` - "documents" is an array of objects containing at least one key.
- `%.#:( $ IS STRING )` - JSON object contains at least one array of strings.
- `#.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `#( $ < 10 AND $ > 20 )` - there is an element that is both less than 10 and greater than 20 (impossible).
- `$( $ >= 10 AND $ <= 20 )` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance [0,30].

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
    id serial,
```

```
data jsonb,  
CHECK (data @@ '  
    name IS STRING AND  
    similar_ids.#: IS NUMERIC AND  
    points.#:(x IS NUMERIC AND y IS NUMERIC) '::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar\_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](https://www.pgconf.eu/presentation) for more examples.

### F.26.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- jsonb\_path\_value\_ops
- jsonb\_value\_path\_ops

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{ "a": [{ "b": "xyz", "c": true }, 10], "d": { "e": [7, false] } }` would be decomposed into the following entries:

- "a".#."b"."xyz"
- "a".#."c".true
- "a".#.10
- "d"."e".#.7
- "d"."e".#.false

Since JsQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

#### F.26.3.1. jsonb\_path\_value\_ops

jsonb\_path\_value\_ops represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

#### F.26.3.2. jsonb\_value\_path\_ops

jsonb\_value\_path\_ops represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all

the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and \* in their paths.

### F.26.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- `gin_debug_query_path_value(jsquery)` - for `jsonb_path_value_ops`
- `gin_debug_query_value_path(jsquery)` - for `jsonb_value_path_ops`

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                      +
  x = 1 , entry 0        +
  OR                      +
    *.y = 1 , entry 1    +
    y = 2 , entry 2      +
```

Unfortunately, `jsonb` has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality (`x = c`)
2. Range (`c1 < x < c2`)
3. Inequality (`x > c`)
4. Is (`x is type`)
5. Any (`x = *`)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                      +
  x = 1 , entry 0        +
  y > 0 , entry 1        +
```

```
SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
y > 0 , entry 0          +
```

## F.26.5. Credits

Development is sponsored by [Wargaming.net](http://Wargaming.net).

## F.27. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

### F.27.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

### F.27.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);

CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo`

columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

### F.27.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

### F.27.4. Author

Peter Mount <peter@retep.org.uk>

## F.28. ltree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

### F.28.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. For example:

|                      |                                                      |
|----------------------|------------------------------------------------------|
| <code>foo</code>     | <i>Match the exact label path foo</i>                |
| <code>*.foo.*</code> | <i>Match any label path containing the label foo</i> |
| <code>*.foo</code>   | <i>Match any label path whose last label is foo</i>  |

Star symbols can also be quantified to restrict how many labels they can match:

|                    |                                                            |
|--------------------|------------------------------------------------------------|
| <code>{n}</code>   | <i>Match exactly n labels</i>                              |
| <code>{n,}</code>  | <i>Match at least n labels</i>                             |
| <code>{n,m}</code> | <i>Match at least n but not more than m labels</i>         |
| <code>{,m}</code>  | <i>Match at most m labels – same as <code>{0,m}</code></i> |

There are several modifiers that can be put at the end of a non-star label in `lquery` to make it match more than just the exact match:

|                |                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------|
| <code>@</code> | <i>Match case-insensitively, for example <code>a@</code> matches <code>A</code></i>                |
| <code>*</code> | <i>Match any label with this prefix, for example <code>foo*</code> matches <code>foobar</code></i> |

% *Match initial underscore-separated words*

The behavior of % is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified labels separated with `|` (OR) to match any of those labels, and you can put `!` (NOT) at the start to match any label that doesn't match any of the alternatives.

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis.Russ*|Spain
a.  b.      c.      d.      e.
```

This query will match any label path that:

- a. begins with the label `Top`
  - b. and next has zero to two labels before
  - c. a label beginning with the case-insensitive prefix `sport`
  - d. then a label not matching `football` nor `tennis`
  - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when % is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

## F.28.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.18](#) are available.

**Table F.18. `ltree` Operators**

| Operator                       | Returns | Description                                                     |
|--------------------------------|---------|-----------------------------------------------------------------|
| <code>ltree @&gt; ltree</code> | boolean | is left argument an ancestor of right (or equal)?               |
| <code>ltree &lt;@ ltree</code> | boolean | is left argument a descendant of right (or equal)?              |
| <code>ltree ~ lquery</code>    | boolean | does <code>ltree</code> match <code>lquery</code> ?             |
| <code>lquery ~ ltree</code>    | boolean | does <code>ltree</code> match <code>lquery</code> ?             |
| <code>ltree ? lquery[]</code>  | boolean | does <code>ltree</code> match any <code>lquery</code> in array? |

| Operator                          | Returns | Description                                                                       |
|-----------------------------------|---------|-----------------------------------------------------------------------------------|
| <code>lquery[] ? ltree</code>     | boolean | does <code>ltree</code> match any <code>lquery</code> in array?                   |
| <code>ltree @ ltxtquery</code>    | boolean | does <code>ltree</code> match <code>ltxtquery</code> ?                            |
| <code>ltxtquery @ ltree</code>    | boolean | does <code>ltree</code> match <code>ltxtquery</code> ?                            |
| <code>ltree    ltree</code>       | ltree   | concatenate <code>ltree</code> paths                                              |
| <code>ltree    text</code>        | ltree   | convert <code>text</code> to <code>ltree</code> and concatenate                   |
| <code>text    ltree</code>        | ltree   | convert <code>text</code> to <code>ltree</code> and concatenate                   |
| <code>ltree[] @&gt; ltree</code>  | boolean | does array contain an ancestor of <code>ltree</code> ?                            |
| <code>ltree &lt;@ ltree[]</code>  | boolean | does array contain an ancestor of <code>ltree</code> ?                            |
| <code>ltree[] &lt;@ ltree</code>  | boolean | does array contain a descendant of <code>ltree</code> ?                           |
| <code>ltree @&gt; ltree[]</code>  | boolean | does array contain a descendant of <code>ltree</code> ?                           |
| <code>ltree[] ~ lquery</code>     | boolean | does array contain any path matching <code>lquery</code> ?                        |
| <code>lquery ~ ltree[]</code>     | boolean | does array contain any path matching <code>lquery</code> ?                        |
| <code>ltree[] ? lquery[]</code>   | boolean | does <code>ltree</code> array contain any path matching any <code>lquery</code> ? |
| <code>lquery[] ? ltree[]</code>   | boolean | does <code>ltree</code> array contain any path matching any <code>lquery</code> ? |
| <code>ltree[] @ ltxtquery</code>  | boolean | does array contain any path matching <code>ltxtquery</code> ?                     |
| <code>ltxtquery @ ltree[]</code>  | boolean | does array contain any path matching <code>ltxtquery</code> ?                     |
| <code>ltree[] ?@&gt; ltree</code> | ltree   | first array entry that is an ancestor of <code>ltree</code> ; NULL if none        |
| <code>ltree[] ?&lt;@ ltree</code> | ltree   | first array entry that is a descendant of <code>ltree</code> ; NULL if none       |
| <code>ltree[] ?~ lquery</code>    | ltree   | first array entry that matches <code>lquery</code> ; NULL if none                 |
| <code>ltree[] ?@ ltxtquery</code> | ltree   | first array entry that matches <code>ltxtquery</code> ; NULL if none              |

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.19](#).

**Table F.19. ltree Functions**

| Function                                         | Return Type | Description                                                    | Example                                          | Result |
|--------------------------------------------------|-------------|----------------------------------------------------------------|--------------------------------------------------|--------|
| <code>subltree(ltree, int start, int end)</code> | ltree       | subpath of <code>ltree</code> from position <code>start</code> | <code>subltree('Top.Child1.Child2', 1, 2)</code> | Child1 |

| Function                                         | Return Type        | Description                                                                                                                                                                                                                                        | Example                                                  | Result                     |
|--------------------------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|----------------------------|
|                                                  |                    | to position <i>end-1</i> (counting from 0)                                                                                                                                                                                                         |                                                          |                            |
| <code>subpath(ltree, int offset, int len)</code> | <code>ltree</code> | subpath of <code>ltree</code> starting at position <i>offset</i> , length <i>len</i> . If <i>offset</i> is negative, subpath starts that far from the end of the path. If <i>len</i> is negative, leaves that many labels off the end of the path. | <code>subpath('Top.Child1.Child2', 0, 2)</code>          | <code>Top.Child1</code>    |
| <code>subpath(ltree, int offset)</code>          | <code>ltree</code> | subpath of <code>ltree</code> starting at position <i>offset</i> , extending to end of path. If <i>offset</i> is negative, subpath starts that far from the end of the path.                                                                       | <code>subpath('Top.Child1.Child2', 1)</code>             | <code>Child1.Child2</code> |
| <code>nlevel(ltree)</code>                       | integer            | number of labels in path                                                                                                                                                                                                                           | <code>nlevel('Top.Child1.Child2')</code>                 | 3                          |
| <code>index(ltree a, ltree b)</code>             | integer            | position of first occurrence of <i>b</i> in <i>a</i> ; -1 if not found                                                                                                                                                                             | <code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6')</code>     | 6                          |
| <code>index(ltree a, ltree b, int offset)</code> | integer            | position of first occurrence of <i>b</i> in <i>a</i> , searching starting at <i>offset</i> ; negative <i>offset</i> means start <i>-offset</i> labels from the end of the path                                                                     | <code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4)</code> | 9                          |
| <code>text2ltree(text)</code>                    | <code>ltree</code> | cast text to ltree                                                                                                                                                                                                                                 |                                                          |                            |
| <code>ltree2text(ltree)</code>                   | text               | cast ltree to text                                                                                                                                                                                                                                 |                                                          |                            |
| <code>lca(ltree, ltree, ...)</code>              | <code>ltree</code> | longest common ancestor of paths (up to 8 arguments supported)                                                                                                                                                                                     | <code>lca('1.2.3', '1.2.3.4.5.6')</code>                 | 1.2                        |
| <code>lca(ltree[])</code>                        | <code>ltree</code> | longest common ancestor of paths in array                                                                                                                                                                                                          | <code>lca(array['1.2.3'::1-tree, '1.2.3.4'])</code>      | 1.2                        |

### F.28.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`

- GiST index over ltree: <, <=, =, >=, >, @>, <@, @, ~, ?

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

- GiST index over ltree[]: ltree[] <@ ltree, ltree @> ltree[], @, ~, ?

Example of creating such an index:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Note: This index type is lossy.

## F.28.4. Example

This example uses the following data (also available in file `contrib/ltree/ltreetest.sql` in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table `test` populated with data describing the hierarchy shown below:

```

              Top
            /  |  \
      Science Hobbies Collections
        /      |      \
    Astronomy Amateurs_Astronomy Pictures
      /  \                |
Astrophysics Cosmology      Astronomy
                        /  |  \
                        Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
```

path

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!pictures@.*.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2) || 'Space' || subpath(path,2) FROM test WHERE path <@
           'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;
```

```
ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
           'Top.Science.Astronomy';
           ins_label
```

```
-----
Top.Science.Space.Astronomy
```

```
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

## F.28.5. Transforms

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see [Section 47.1](#) for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

### Caution

It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

## F.28.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

## F.29. mchar

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

### F.29.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use `libicu` for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes [citext](#) extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

### F.29.2. Additional types

- `mchar` — analog of the MS SQL `char` type
- `mvarchar` — analog of the MS SQL `varchar` type

### F.29.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments

- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (LibICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (LibICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the `LIKE` operator

## F.29.4. Authors

Oleg Bartunov <oleg@sai.msu.ru>  
Teodor Sigaev <teodor@sigaev.ru>

## F.30. multimaster

`multimaster` is a Postgres Pro Enterprise extension with a set of patches that turns Postgres Pro Enterprise into a synchronous shared-nothing cluster to provide Online Transaction Processing (OLTP) scalability for read transactions and high availability with automatic disaster recovery.

As compared to a standard PostgreSQL master-standby cluster, a cluster configured with the `multi-master` extension offers the following benefits:

- Fault tolerance and automatic node recovery
- Synchronous logical replication and DDL replication
- Read scalability
- Working with temporary tables on each cluster node
- Postgres Pro Enterprise online upgrades

### Important

The `multimaster` extension is no longer supported in Postgres Pro Enterprise 11. Please consider migrating to the latest Postgres Pro Enterprise major version to ensure stable performance of `multimaster`.

### Note

Before deploying `multimaster` on production systems, make sure to take its replication restrictions into account. For details, see [Section F.30.1](#).

The `multimaster` extension replicates your database to all nodes of the cluster and allows write transactions on each node. Write transactions are synchronously replicated to all nodes, which increases commit latency. Read-only transactions and queries are executed locally, without any measurable overhead.

To ensure high availability and fault tolerance of the cluster, `multimaster` uses three-phase commit protocol and heartbeats for failure discovery. A multi-master cluster of  $N$  nodes can continue working while the majority of the nodes are alive and reachable by other nodes. To be configured with `multimaster`, the cluster must include at least two nodes. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes. Three cluster nodes are enough to ensure high availability in

most cases. For best experience, it is recommended to set up two data nodes and a referee, as explained in [Section F.30.3.3](#).

When a failed node is reconnected to the cluster, `multimaster` can automatically fast-forward the node to the actual state based on the Write-Ahead Log (WAL) data in the corresponding replication slot. If a node was excluded from the cluster, you can [add it back using `pg\_basebackup`](#).

To learn more about the `multimaster` internals, see [Section F.30.2](#).

## F.30.1. Limitations

The `multimaster` extension takes care of the database replication in a fully automated way. You can perform write transactions on any node and work with temporary tables on each cluster node simultaneously. However, make sure to take the following replication restrictions into account:

- Microsoft Windows operating system is not supported.
- 1C solutions are not supported.
- `multimaster` can replicate only one database in a cluster. If it is required to replicate the contents of several databases, you can either transfer all data into different schemas within a single database or create a separate cluster for each database and set up `multimaster` for each cluster.
- [Large objects](#) are not supported. Although creating large objects is allowed, `multimaster` cannot replicate such objects, and their OIDs may conflict on different nodes, so their use is not recommended.
- Since `multimaster` is based on [logical replication and three-phase E3PC commit protocol](#), its operation is highly affected by network latency. It is not recommended to set up a `multimaster` cluster with geographically distributed nodes.
- Using tables without primary keys can have negative impact on performance. In some cases, it can even lead to inability to restore a cluster node, so you should avoid replicating such tables with `multimaster`.
- Unlike in vanilla PostgreSQL, `read committed` isolation level can cause serialization failures on a multi-master cluster (with an SQLSTATE code '40001') if there are conflicting transactions from different nodes, so the application must be ready to retry transactions. *Serializable* isolation level works only with respect to local transactions on the current node.
- Sequence generation. To avoid conflicts between unique identifiers on different nodes, `multimaster` modifies the default behavior of sequence generators. By default, ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly. Thus, the generated sequence values are not monotonic. If it is critical to get a monotonically increasing sequence cluster-wide, you can set the `multimaster.monotonic_sequences` to `true`.
- Commit latency. In the current implementation of logical replication, `multimaster` sends data to subscriber nodes only after the local commit, so you have to wait for transaction processing twice: first on the local node, and then on all the other nodes simultaneously. In the case of a heavy-write transaction, this may result in a noticeable delay.
- Logical replication does not guarantee that a system object OID is the same on all cluster nodes, so OIDs for the same object may differ between `multimaster` cluster nodes. If your driver or application relies on OIDs, make sure that their use is restricted to connections to one and the same node to avoid errors. For example, the `Npgsql` driver may not work correctly with `multimaster` if the `NpgsqlConnection.GlobalTypeMapper` method tries using OIDs in connections to different cluster nodes.
- Replicated non-conflicting transactions are applied on the receiving nodes in parallel, so such transactions may become visible on different nodes in different order.
- `CREATE INDEX CONCURRENTLY` and `REINDEX CONCURRENTLY` are not supported.

- `COMMIT AND CHAIN` feature is not supported.

## F.30.2. Architecture

### F.30.2.1. Replication

Since each server in a multi-master cluster can accept writes, any server can abort a transaction because of a concurrent update — in the same way as it happens on a single server between different backends. To ensure high availability and data consistency on all cluster nodes, `multimaster` uses [logical replication](#) and the [three-phase E3PC commit protocol](#).

When Postgres Pro Enterprise loads the `multimaster` shared library, `multimaster` sets up a logical replication producer and consumer for each node, and hooks into the transaction commit pipeline. The typical data replication workflow consists of the following phases:

1. **PREPARE phase.** `multimaster` captures and implicitly transforms each `COMMIT` statement to a `PREPARE` statement. All the nodes that get the transaction via the replication protocol (*the cohort nodes*) send their vote for approving or declining the transaction to the backend process on the initiating node. This ensures that all the cohort can accept the transaction, and no write conflicts occur. For details on `PREPARE` transactions support in PostgreSQL, see the [PREPARE TRANSACTION](#) topic.
2. **PRECOMMIT phase.** If all the cohort nodes approve the transaction, the backend process sends a `PRECOMMIT` message to all the cohort nodes to express an intention to commit the transaction. The cohort nodes respond to the backend with the `PRECOMMITTED` message. In case of a failure, all the nodes can use this information to complete the transaction using a quorum-based voting procedure.
3. **COMMIT phase.** If `PRECOMMIT` is successful, the transaction is committed to all nodes.

If a node crashes or gets disconnected from the cluster between the `PREPARE` and `COMMIT` phases, the `PRECOMMIT` phase ensures that the survived nodes have enough information to complete the prepared transaction. The `PRECOMMITTED` messages help avoid the situation when the crashed node has already committed or aborted the transaction, but has not notified other nodes about the transaction status. In a two-phase commit (2PC), such a transaction would block resources (hold locks) until the recovery of the crashed node. Otherwise, data inconsistencies can appear in the database when the failed node is recovered, for example, if the failed node committed the transaction, but the survived node aborted it.

To complete the transaction, the backend must receive a response from the majority of the nodes. For example, for a cluster of  $2N+1$  nodes, at least  $N+1$  responses are required. Thus, `multimaster` ensures that your cluster is available for reads and writes while the majority of the nodes are connected, and no data inconsistencies occur in case of a node or connection failure.

### F.30.2.2. Failure Detection and Recovery

Since `multimaster` allows writes to each node, it has to wait for responses about transaction acknowledgment from all the other nodes. Without special actions in case of a node failure, each commit would have to wait until the failed node recovery. To deal with such situations, `multimaster` periodically sends heartbeats to check the node state and the connectivity between nodes. When several heartbeats to the node are lost in a row, this node is kicked out of the cluster to allow writes to the remaining alive nodes. You can configure the heartbeat frequency and the response timeout in the `multimaster.heartbeat_send_timeout` and `multimaster.heartbeat_recv_timeout` parameters, respectively.

For example, suppose a five-node multi-master cluster experienced a network failure that split the network into two isolated subnets, with two and three cluster nodes. Based on heartbeats propagation information, `multimaster` will continue accepting writes at each node in the bigger partition, and deny all writes in the smaller one. Thus, a cluster consisting of  $2N+1$  nodes can tolerate  $N$  node failures and stay alive if any  $N+1$  nodes are alive and connected to each other.

In case of a partial network split when different nodes have different connectivity, `multimaster` finds a fully connected subset of nodes and disconnects nodes outside of this subset. For example, in a three-node cluster, if node A can access both B and C, but node B cannot access node C, `multimaster` isolates node C to ensure that both A and B can work.

For clusters with an even number of nodes, you can set up a lightweight referee node that does not hold the data, but acts as a tie-breaker during symmetric node partitioning. For details, see [Section F.30.3.3](#).

For alive nodes, there is no way to distinguish between a failed node that stopped serving requests and a network-partitioned node that can be accessed by database users, but is unreachable for other nodes. To avoid conflicting writes to nodes in different network partitions, `multimaster` only allows writes to the nodes that see the majority of other nodes. If you try to access a disconnected node, `multimaster` returns an error message indicating the current status of the node. To prevent stale reads, read-only queries are also forbidden. Thus, if you would like to continue using a disconnected node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension on this node, as explained in [Section F.30.4.5](#).

Each node maintains a data structure that keeps the information about the state of all nodes in relation to this node. You can get this data by calling the `mtm.status()` and the `mtm.nodes()` functions.

When a failed node connects back to the cluster, `multimaster` starts automatic recovery:

1. The reconnected node selects a random cluster node and starts catching up with the current state of the cluster based on the Write-Ahead Log (WAL). All the cluster nodes get locked for write transactions to allow the recovery process to finish.
2. When the recovery is complete, `multimaster` promotes the reconnected node to the online state and includes it into the replication scheme.

Automatic recovery requires presence of all WAL files generated after node failure. If a node is down for a long time and WAL files are no longer available, you may have to exclude this node from the cluster and manually restore it from one of the working nodes using `pg_basebackup`. For details, see [Section F.30.4.3](#).

### F.30.2.3. Multimaster Background Workers

#### `mtm-monitor`

Starts all other workers for a database managed with `multimaster`. This is the first worker loaded during `multimaster` boot. Each `multimaster` node has a single `mtm-monitor` worker. When a new node is added, `mtm-monitor` starts `mtm-logrep-receiver` and `mtm-dmq-receiver` workers to enable replication to this node. If a node is dropped, `mtm-monitor` stops `mtm-logrep-receiver` and `mtm-dmq-receiver` workers that have been serving the dropped node. Each `mtm-monitor` controls workers on its own node only.

#### `mtm-logrep-receiver`

Receives logical replication stream from a given peer node. During recovery, all received transactions are applied by `mtm-logrep-receiver`. During normal operation, `mtm-logrep-receiver` passes transactions to the pool of dynamic workers (see [mtm-logrep-receiver-dynworker](#)). The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

#### `mtm-dmq-receiver`

Receives acknowledgment for transactions sent to peers and checks for heartbeat timeouts. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

#### `mtm-dmq-sender`

Collects acknowledgment for transactions applied on the current node and sends them to the corresponding [mtm-dmq-receiver](#) on the peer node. There is a single `mtm-dmq-sender` worker per Postgres Pro instance.

#### `mtm-logrep-receiver-dynworker`

Dynamic pool worker for a given [mtm-logrep-receiver](#). Applies the replicated transaction received during normal operation. There are up to `multimaster.max_workers` workers per each peer node.

## mtm-resolver

Asks all peers about the status of unfinished transactions to resolve them according to 3PC rules. This worker is only active during recovery.

### F.30.3. Installation and Setup

To use `multimaster`, you need to install Postgres Pro Enterprise on all nodes of your cluster. Postgres Pro Enterprise includes all the required dependencies and extensions. For best experience, it is recommended to set up two data nodes and a referee, as explained in [Section F.30.3.3](#).

#### F.30.3.1. Setting up a Multi-Master Cluster

Suppose you are setting up a cluster of three nodes, with `node1`, `node2`, and `node3` host names. After installing Postgres Pro Enterprise on all nodes, you need to initialize data directory on each node, as explained in [Section 18.2](#). If you would like to set up a multi-master cluster for an already existing `mydb` database, you can load data from `mydb` to one of the nodes once the cluster is initialized, or you can load data to all new nodes before cluster initialization using any convenient mechanism, such as `pg_basebackup` or `pg_dump`.

Once the data directory is set up, complete the following steps on each cluster node:

1. Modify the `postgresql.conf` configuration file, as follows:

- Add `multimaster` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'multimaster'
```

#### Tip

If the `shared_preload_libraries` variable is already defined in `postgresql.auto.conf`, you will need to modify its value using the `ALTER SYSTEM` command. For details, see [Section 19.1.2](#). Note that in a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the node from which it was run.

- Set up Postgres Pro parameters related to replication:

```
wal_level = logical
max_connections = 100
max_prepared_transactions = 300 # max_connections * N
max_wal_senders = 10           # at least N
max_replication_slots = 10     # at least 2N
wal_sender_timeout = 0
```

where  $N$  is the number of nodes in your cluster.

You must change the replication level to `logical` as `multimaster` relies on logical replication. For a cluster of  $N$  nodes, enable at least  $N$  WAL sender processes and replication slots. Since `multimaster` implicitly adds a `PREPARE` phase to each `COMMIT` transaction, make sure to set the number of prepared transactions to  $N * \text{max\_connections}$ . `wal_sender_timeout` should be disabled as `multimaster` uses its custom logic for failure detection.

- Make sure you have enough background workers allocated for each node:

```
max_worker_processes = 250 # (N - 1) * (max_connections + 3) + 3
```

For example, for a three-node cluster with `max_connections = 100`, `multimaster` may need up to 209 background workers at peak times: three always-on workers (monitor, resolver, dmq-sender), three workers per each peer node (walsender, mtm-receiver, dmq-receiver) and up to 200 replication dynamic workers (that is, `max_connections` workers per each peer node). When

setting this parameter, remember that other modules may also use background workers at the same time.

- Depending on your network environment and usage patterns, you may want to tune other `multimaster` parameters. For details, see [Section F.30.3.2](#).

2. Start Postgres Pro Enterprise on all nodes.

3. Create database `mydb` and user `mtmuser` on each node:

```
CREATE USER mtmuser WITH SUPERUSER PASSWORD 'mtmuserpassword';
CREATE DATABASE mydb OWNER mtmuser;
```

If you are using password-based authentication, you may want to create a [password file](#).

You can omit this step if you already have a database you are going to replicate, but you are recommended to create a separate superuser for multi-master replication. The examples below assume that you are going to replicate the `mydb` database on behalf of `mtmuser`.

4. Allow replication of the `mydb` database to each cluster node on behalf of `mtmuser`, as explained in [Section 20.1](#). Make sure to use the [authentication method](#) that satisfies your security requirements. For example, `pg_hba.conf` might have the following lines on `node1`:

```
host replication mtmuser node2 md5
host mydb mtmuser node2 md5
host replication mtmuser node3 md5
host mydb mtmuser node3 md5
```

5. Connect to any node on behalf of the `mtmuser` database user, create the `multimaster` extension in the `mydb` database and run `mtm.init_cluster()`, specifying the connection string to the current node as the first argument and an array of connection strings to the other nodes as the second argument.

For example, if you would like to connect to `node1`, run:

```
CREATE EXTENSION multimaster;
SELECT mtm.init_cluster('dbname=mydb user=mtmuser host=node1',
'{"dbname=mydb user=mtmuser host=node2", "dbname=mydb user=mtmuser host=node3"}');
```

6. To ensure that `multimaster` is enabled, you can run the `mtm.status()` and `mtm.nodes()` functions:

```
SELECT * FROM mtm.status();
SELECT * FROM mtm.nodes();
```

If `status` is equal to `online` and all nodes are present in the `mtm.nodes` output, your cluster is successfully configured and ready to use.

### Tip

If you have any data that must be present on one of the nodes only, you can exclude a particular table from replication, as follows:

```
SELECT mtm.make_table_local('table_name')
```

## F.30.3.2. Tuning Configuration Parameters

While you can use `multimaster` in the default configuration, you may want to tune several parameters for faster failure detection or more reliable automatic recovery.

### F.30.3.2.1. Setting Timeout for Failure Detection

To check availability of the peer nodes, `multimaster` periodically sends heartbeat packets to all nodes. You can define the timeout for failure detection with the following variables:

- The `multimaster.heartbeat_send_timeout` variable defines the time interval between the heartbeats. By default, this variable is set to 200ms.

- The `multimaster.heartbeat_recv_timeout` variable sets the timeout for the response. If no heartbeats are received during this time, the node is assumed to be disconnected and is excluded from the cluster. By default, this variable is set to 2000ms.

It's a good idea to set `multimaster.heartbeat_send_timeout` based on typical ping latencies between the nodes. Small recv/send ratio decreases the time of failure detection, but increases the probability of false-positive failure detection. When setting this parameter, take into account the typical packet loss ratio between your cluster nodes.

### F.30.3.3. Setting up a Standalone Referee Node

By default, `multimaster` uses a majority-based algorithm to determine whether the cluster nodes have a quorum: a cluster can only continue working if the majority of its nodes are alive and can access each other. For clusters with an even number of nodes, this approach is not optimal. For example, if a network failure splits the cluster into equal parts, or one of the nodes fails in a two-node cluster, all the nodes stop accepting queries, even though at least half of the cluster nodes are running normally.

To enable a smooth failover for such cases, you can set up a standalone *referee* node to assign the quorum status to a subset of nodes that constitutes half of the cluster.

A *referee* is a voting node used to determine which subset of nodes has a quorum if the cluster is split into equal parts. The referee node does not store any cluster data, so it is not resource-intensive and can be configured on virtually any system with Postgres Pro Enterprise installed.

To avoid split-brain problems, you can only have a single referee in your cluster.

To set up a referee for your cluster:

1. Install Postgres Pro Enterprise on the node you are going to make a referee and create the `referee` extension:

```
CREATE EXTENSION referee;
```

2. Make sure the `pg_hba.conf` file allows access to the referee node.
3. Set up the nodes that will hold cluster data following the instructions in [Section F.30.3.1](#). For best experience, it is recommended to set up two data nodes.
4. On all data nodes, specify the referee connection string in the `postgresql.conf` file:

```
multimaster.referee_connstring = connstring
```

where *connstring* holds [libpq options](#) required to access the referee.

The first subset of nodes that gets connected to the referee wins the voting and starts working. The other nodes have to go through the recovery process to catch up with them and join the cluster. Under heavy load, the recovery can take unpredictably long, so it is recommended to wait for all data nodes going online before switching on the load when setting up a new cluster. Once all the nodes get online, the referee discards the voting result, and all data nodes start operating together.

In case of any failure, the voting mechanism is triggered again. At this time, all nodes appear to be offline for a short period of time to allow the referee to choose a new winner, so you can see the following error message when trying to access the cluster: `[multimaster] node is not online: current status is "disabled"`.

## F.30.4. Multi-Master Cluster Administration

- [Monitoring the Cluster Status](#)
- [Accessing Disabled Nodes](#)
- [Adding New Nodes to the Cluster](#)
- [Removing Nodes from the Cluster](#)

- [Checking Data Consistency Across Cluster Nodes](#)

### F.30.4.1. Monitoring Cluster Status

`multimaster` provides several functions to check the current cluster state.

To check node-specific information, use `mtm.status()`:

```
SELECT * FROM mtm.status();
```

To get the list of all nodes in the cluster together with their status, use `mtm.nodes()`:

```
SELECT * FROM mtm.nodes();
```

For details on all the returned information, see [Section F.30.5.2](#).

### F.30.4.2. Accessing Disabled Nodes

If a cluster node is disabled, any attempt to read or write data on this node raises an error by default. If you need to access the data on a disabled node, you can override this behavior at connection time by setting the [application\\_name](#) parameter to `mtm_admin`. In this case, you can run read and write queries on this node without `multimaster` supervision.

### F.30.4.3. Adding New Nodes to the Cluster

With the `multimaster` extension, you can add or drop cluster nodes without stopping the database service. When adding a new node, you need to load all the data to this node using `pg_basebackup` from any cluster node, and then start this node.

Suppose we have a working cluster of three nodes, with `node1`, `node2`, and `node3` host names. To add `node4`, follow these steps:

1. Figure out the required connection string to access the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string can be `"dbname=mydb user=mtmuser host=node4"`.

2. In `psql` connected to any alive node, run:

```
SELECT mtm.add_node('dbname=mydb user=mtmuser host=node4');
```

This command changes the cluster configuration on all nodes and creates replication slots for the new node. It also returns `node_id` of the new node, which will be required to complete the setup.

3. Go to the new node and clone all the data from one of the alive nodes to this node:

```
pg_basebackup -D datadir -h node1 -U mtmuser -c fast -v
```

`pg_basebackup` copies the entire data directory from `node1`, together with configuration settings, and prints the last LSN replayed from WAL, such as `'0/12D357F0'`. This value will be required to complete the setup.

4. Start Postgres Pro on the new node.

5. In `psql` connected to the node used to take the base backup, run:

```
SELECT mtm.join_node(4, '0/12D357F0');
```

where 4 is the `node_id` returned by the `mtm.add_node()` function call and `'0/12D357F0'` is the LSN value returned by `pg_basebackup`.

### F.30.4.4. Removing Nodes from the Cluster

To remove the node from the cluster:

1. Run the `mtm.nodes()` function to learn the ID of the node to be removed:

```
SELECT * FROM mtm.nodes();
```

2. Run the `mtm.drop_node()` function with this node ID as a parameter:

```
SELECT mtm.drop_node(3);
```

This will delete replication slots for node 3 on all cluster nodes and stop replication to this node.

If you would like to return the node to the cluster later, you will have to add it as a new node, as explained in [Section F.30.4.3](#).

### F.30.4.5. Uninstalling the multimaster Extension

If you would like to continue using the node that has been removed from the cluster in the standalone mode, you have to drop the `multimaster` extension on this node and clean up all `multimaster`-related subscriptions and uncommitted transactions to ensure that the node is no longer associated with the cluster.

1. Remove `multimaster` from [shared\\_preload\\_libraries](#) and restart Postgres Pro Enterprise.
2. Delete the `multimaster` extension and publication:

```
DROP EXTENSION multimaster;  
DROP PUBLICATION multimaster;
```

3. Review the list of existing subscriptions using the `\dRs` command and delete each subscription that starts with the `mtm_sub_` prefix:

```
\dRs  
DROP SUBSCRIPTION mtm_sub_subscription_name;
```

4. Review the list of existing replication slots and delete each slot that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_slots;  
SELECT pg_drop_replication_slot('mtm_slot_name');
```

5. Review the list of existing replication origins and delete each origin that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_origin;  
SELECT pg_replication_origin_drop('mtm_origin_name');
```

6. Review the list of prepared transaction left, if any:

```
SELECT * FROM pg_prepared_xacts;
```

You have to commit or abort these transactions by running `ABORT PREPARED transaction_id` or `COMMIT PREPARED transaction_id`, respectively.

Once all these steps are complete, you can start using the node in the standalone mode, if required.

### F.30.4.6. Checking Data Consistency Across Cluster Nodes

You can check that the data is the same on all cluster nodes using the [mtm.check\\_query\(query\\_text\)](#) function.

As a parameter, this function takes the text of a query you would like to run for data comparison. When you call this function, it takes a consistent snapshot of data on each cluster node and runs this query against the captured snapshots. The query results are compared between pairs of nodes. If there are no differences, this function returns `true`. Otherwise, it reports the first detected difference in a warning and returns `false`.

To avoid false-positive results, always use the `ORDER BY` clause in your test query. For example, suppose you would like to check that the data in a `my_table` is the same on all cluster nodes. Compare the results of the following queries:

```
postgres=# SELECT mtm.check_query('SELECT * FROM my_table ORDER BY id');  
check_query
```

```
-----  
t  
(1 row)  
  
postgres=# SELECT mtm.check_query('SELECT * FROM my_table');  
WARNING: mismatch in column 'b' of row 0: 256 on node0, 255 on node1  
check_query  
-----  
  
f  
(1 row)
```

Even though the data is the same, the second query reports an issue because the order of the returned data differs between cluster nodes.

## F.30.5. Reference

### F.30.5.1. Configuration Parameters

`multimaster.heartbeat_recv_timeout`

Timeout, in milliseconds. If no heartbeat message is received from the node within this timeframe, the node is excluded from the cluster.

Default: 2000 ms

`multimaster.heartbeat_send_timeout`

Time interval between heartbeat messages, in milliseconds. A multimaster node broadcasts heartbeat messages to all peers to detect connection problems.

Default: 200 ms

`multimaster.max_workers`

The maximum number of `walreceiver` workers per peer node.

#### Important

This parameter should be used with caution. If the number of simultaneous transactions in the whole cluster is bigger than the provided value, it can lead to undetected deadlocks.

Default: 100

`multimaster.monotonic_sequences`

Defines the sequence generation mode for unique identifiers. This variable can take the following values:

- `false` (default) — ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly.
- `true` — the generated sequence increases monotonically cluster-wide. ID generation on each node is started with this node number and is incremented by the number of nodes, but the values are omitted if they are smaller than the already generated IDs on another node. For example, in a three-node cluster, if 1, 4 and 7 IDs are already allocated to the objects on the first node, 2 and 5 IDs will be omitted on the second node. In this case, the first ID on the second node is 8. Thus, the next generated ID is always higher than the previous one, regardless of the cluster node.

Default: `false`

`multimaster.referee_connstring`

Connection string to access the referee node. You must set this parameter on all cluster nodes if the referee is set up.

`multimaster.remote_functions`

Provides a comma-separated list of function names that should be executed remotely on all multimaster nodes instead of replicating the result of their work.

`multimaster.trans_spill_threshold`

The maximal size of transaction, in kB. When this threshold is reached, the transaction is written to the disk.

Default: 100MB

`multimaster.break_connection`

Break connection with clients connected to the node if this node disconnects from the cluster. If this variable is set to `false`, the client stays connected to the node but receives an error that the node is disabled.

Default: `false`

### F.30.5.2. Functions

`mtm.init_cluster(my_conninfo text, peers_conninfo text[])`

Initializes cluster configuration on all nodes. It connects the current node to all nodes listed in `peer-s_conninfo` and creates the multimaster extension, replications slots, and replication origins on each node. Run this function once all the nodes are running and can accept connections.

Arguments:

- `my_conninfo` — connection string to the node on which you are running this function. Peer nodes use this string to connect back to this node.
- `peers_conninfo` — an array of connection strings to all the other nodes to be added to the cluster.

`mtm.add_node(connstr text)`

Adds a new node to the cluster. This function should be called before loading data to this node using `pg_basebackup`. `mtm.add_node` creates the required replication slots for a new node, so you can add a node while the cluster is under load.

Arguments:

- `connstr` — connection string for the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string is `"dbname=mydb user=mtmuser host=node4"`.

`mtm.join_node(node_id int, backup_end_lsn pg_lsn)`

Completes the cluster setup after adding a new node. This function should be called after the added node has been started.

Arguments:

- `node_id` — ID of the node to add to the cluster. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

*backup\_end\_lsn* — the last LSN of the base backup copied to the new node. This LSN will be used as the starting point for data replication once the node joins the cluster.

`mtm.drop_node(node_id integer)`

Excludes a node from the cluster.

If you would like to continue using this node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension from this node, as explained in [Section F.30.4.5](#).

Arguments:

- *node\_id* — ID of the node being dropped. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

`mtm.alter_sequences()`

Fixes unique identifiers on all cluster nodes. This may be required after restoring all nodes from a single base backup.

`mtm.status()`

Shows the status of the `multimaster` extension on the current node. Returns a tuple of the following values:

- *node\_id, integer* — ID of this node.
- *status, text* — status of the node. Possible values are: `online`, `recovery`, `recovered`, `disabled`.
- *n\_nodes, integer* — number of nodes in the cluster. The majority of alive nodes is calculated based on this parameter.
- *n\_connected, integer* — number of connected nodes.
- *n\_enabled, integer* — number of enabled nodes.

`mtm.nodes()`

Shows the information on all nodes in the cluster. Returns a tuple of the following values:

- *id, integer* — node ID.
- *enabled, boolean* — shows whether the node is fully recovered and is operating normally. The node can only be disabled if responses to heartbeats are not received within the `heartbeat_recv_timeout` time interval. When the node starts responding to heartbeats, `multimaster` can automatically restore the node and switch it back to the enabled state.
- *connected, boolean* — shows whether the node is connected to our node.
- *sender\_pid, integer* — WAL sender process ID.
- *receiver\_pid, integer* — WAL receiver process ID.
- *receiver\_status, text* — status of the node. Possible values are: `recovery`, `recovered`.
- *conninfo, text* — connection string to this node.

`mtm.make_table_local(relation regclass)`

Stops replication for the specified table.

Arguments:

- *relation* — the table you would like to exclude from the replication scheme.

`mtm.check_query(query_text text)`

Checks data consistency across cluster nodes. This function takes a snapshot of the current state of each node, runs the specified query against these snapshots, and compares the results. If the results are different between any two nodes, displays a warning with the first found issue and returns `false`. Otherwise, returns `true`.

Arguments:

- *query\_text* — the query you would like to run on all nodes for data comparison. To avoid false-positive results, always use the `ORDER BY` clause in the test query.

`mtm.get_snapshots()`

Takes a snapshot of data on each cluster node and returns the snapshot ID. The snapshots remain available until the `mtm.free_snapshots()` is called, or the current session is terminated. This function is used by the [mtm.check\\_query\(query\\_text\)](#), there is no need to call it manually.

`mtm.free_snapshots()`

Removes data snapshots taken by the `mtm.get_snapshots()` function. This function is used by the [mtm.check\\_query\(query\\_text\)](#), there is no need to call it manually.

## F.30.6. Compatibility

### F.30.6.1. Local and Global DDL Statements

By default, any DDL statement is executed on all cluster nodes, except the following statements that can only act locally on a given node:

- `ALTER SYSTEM`
- `CREATE DATABASE`
- `DROP DATABASE`
- `REINDEX`
- `CHECKPOINT`
- `CLUSTER`
- `LOAD`
- `LISTEN`
- `CHECKPOINT`
- `NOTIFY`

## F.30.7. Authors

Postgres Professional, Moscow, Russia.

### F.30.7.1. Credits

The replication mechanism is based on logical decoding and an earlier version of the `pglogical` extension provided for community by the 2ndQuadrant team.

The three-phase E3PC commit protocol is described in:

- Idit Keidar, Danny Dolev. [Increasing the Resilience of Distributed and Replicated Database Systems](#).

Parallel replication and recovery mechanism is similar to the one described in:

- Odorico M. Mendizabal, et al. [Checkpointing in Parallel State-Machine Replication](#).

## F.31. online\_analyze

The `online_analyze` module provides a set of features that immediately update statistics after `INSERT`, `UPDATE`, `DELETE`, or `SELECT INTO` operations for the affected tables.

### Note

This extension cannot be used together with autonomous transactions or while built-in connection pooling is enabled.

### F.31.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

### F.31.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

### Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum\\_analyze\\_scale\\_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum\\_analyze\\_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ""`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to off, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

### F.31.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

## F.32. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

### F.32.1. General Functions

`get_raw_page(relname text, fork text, blkno int)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. *fork* should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno int)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn      | checksum | flags  | lower | upper | special | pagesize | version |
   xid_base | multi_base | prune_xid
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
0/24A1B50 |          0 |      1 |    232 |    368 |      8192 |      8192 |      4 |
0 |          0 |          0
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno int4)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
page_checksum
-----
13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents`(page bytea) returns text

`fsm_page_contents` shows the internal node structure of a FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

## F.32.2. Heap Functions

`heap_page_items`(page bytea) returns setof record

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

`tuple_data_split`(rel\_oid oid, t\_data bytea, t\_infomask integer, t\_infomask2 integer, t\_bits text [, do\_detoast bool]) returns bytea[]

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs`(page bytea, rel\_oid regclass [, do\_detoast bool]) returns setof record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
'pg_class'::regclass);
```

## F.32.3. B-tree Functions

`bt_metap`(relname text) returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
```

```
-[ RECORD 1 ]-----+-----
magic          | 340322
version        | 3
root           | 1
level          | 0
fastroot       | 1
fastlevel      | 0
oldest_xact    | 582
last_cleanup_num_tuples | 1000
```

`bt_page_stats(relname text, blkno int)` returns record

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```
test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | 1
live_items    | 256
dead_items    | 0
avg_item_size | 12
page_size     | 8192
free_size     | 4056
btpo_prev     | 0
btpo_next     | 0
btpo          | 0
btpo_flags    | 3
```

`bt_page_items(relname text, blkno int)` returns setof record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```
test=# SELECT * FROM bt_page_items('pg_cast_oid_index', 1);
 itemoffset | ctid  | itemlen | nulls | vars | data
-----+-----+-----+-----+-----+-----
          1 | (0,1) |      12 | f     | f    | 23 27 00 00
          2 | (0,2) |      12 | f     | f    | 24 27 00 00
          3 | (0,3) |      12 | f     | f    | 25 27 00 00
          4 | (0,4) |      12 | f     | f    | 26 27 00 00
          5 | (0,5) |      12 | f     | f    | 27 27 00 00
          6 | (0,6) |      12 | f     | f    | 28 27 00 00
          7 | (0,7) |      12 | f     | f    | 29 27 00 00
          8 | (0,8) |      12 | f     | f    | 2a 27 00 00
```

In a B-tree leaf page, `ctid` points to a heap tuple. In an internal page, the block number part of `ctid` points to another page in the index itself, while the offset part (the second number) is ignored and is usually 1.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field is meaningless. Also, on non-leaf pages, the first real data item (the first item that is not a high key) is a “minus infinity” item, with no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

`bt_page_items(page bytea)` returns setof record

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```
test=# SELECT * FROM bt_page_items(get_raw_page('pg_cast_oid_index', 1));
 itemoffset | ctid  | itemlen | nulls | vars | data
```

## F.32.5. GIN Functions

`gin_metapage_info(page bytea)` returns record

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2
```

`gin_page_opaque_info(page bytea)` returns record

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff | flags
-----+-----+-----
          5 |        0 | {data,leaf,compressed}
(1 row)
```

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
       FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes | some_tids
-----+-----+-----
(8,41)    | 244   | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   | 248   | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   | 248   | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   | 320   | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  | 376   | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  | 376   | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  | 197   | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

## F.32.6. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage
```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
```

```
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket     | 0
hasho_flag       | 66
hasho_page_id    | 65408
```

hash\_page\_items(page bytea) returns setof record

hash\_page\_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid   |   data
-----+-----+-----
          1 | (899,77) | 1053474816
          2 | (897,29) | 1053474816
          3 | (894,207)| 1053474816
          4 | (892,159)| 1053474816
          5 | (890,111)| 1053474816
```

hash\_bitmap\_info(index oid, blkno int) returns record

hash\_bitmap\_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
          65 |          3 | t
```

hash\_metapage\_info(page bytea) returns record

hash\_metapage\_info returns information stored in meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#       maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#       regexp_replace(spares::text, '(.0)*}', '{}') as spares,
test-#       regexp_replace(mapp::text, '(.0)*}', '{}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD
1 ]-----
magic      | 105121344
version    | 4
ntuples    | 500500
ffactor    | 40
bsize      | 8152
bmsize     | 4096
bmshift    | 15
maxbucket  | 12512
highmask   | 16383
lowmask    | 8191
ovflpoint  | 28
firstfree  | 1204
nmaps      | 1
procid     | 450
spares     |
{0,0,0,0,0,0,1,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,508,567,628,704,1193,1202,1204}
mapp       | {65}
```

## F.33. passwordcheck

The `passwordcheck` module checks users' passwords whenever they are set with [CREATE ROLE](#) or [ALTER ROLE](#). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '`$libdir/passwordcheck`' to [shared\\_preload\\_libraries](#) in `postgresql.conf`, then restart the server.

### Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 20](#)) than to rely on passwords within the database.

## F.34. pg\_buffercache

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and members of the `pg_monitor` role. Access may be granted to others using `GRANT`.

### F.34.1. The pg\_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.20](#).

**Table F.20. pg\_buffercache Columns**

| Name                        | Type                  | References                        | Description                                                                 |
|-----------------------------|-----------------------|-----------------------------------|-----------------------------------------------------------------------------|
| <code>bufferid</code>       | <code>integer</code>  |                                   | ID, in the range 1.. <code>shared_buffers</code>                            |
| <code>relfilenode</code>    | <code>oid</code>      | <code>pg_class.relfilenode</code> | Filenode number of the relation                                             |
| <code>reltablespace</code>  | <code>oid</code>      | <code>pg_tablespace.oid</code>    | Tablespace OID of the relation                                              |
| <code>reldatabase</code>    | <code>oid</code>      | <code>pg_database.oid</code>      | Database OID of the relation                                                |
| <code>relforknumber</code>  | <code>smallint</code> |                                   | Fork number within the relation; see <code>include/common/rel-path.h</code> |
| <code>relblocknumber</code> | <code>bigint</code>   |                                   | Page number within the relation                                             |
| <code>isdirty</code>        | <code>boolean</code>  |                                   | Is the page dirty?                                                          |

| Name             | Type     | References | Description                            |
|------------------|----------|------------|----------------------------------------|
| usagecount       | smallint |            | Clock-sweep access count               |
| pinning_backends | integer  |            | Number of backends pinning this buffer |

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

## F.34.2. Sample Output

```

regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;

```

| nspname    | relname                | buffers |
|------------|------------------------|---------|
| public     | delete_test_table      | 593     |
| public     | delete_test_table_pkey | 494     |
| pg_catalog | pg_attribute           | 472     |
| public     | quad_poly_tbl          | 353     |
| public     | tenk2                  | 349     |
| public     | tenk1                  | 349     |
| public     | gin_test_idx           | 306     |
| pg_catalog | pg_largeobject         | 206     |
| public     | gin_test_tbl           | 188     |
| public     | spgist_text_tbl        | 182     |

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

## F.35. pgcrypto

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

### F.35.1. General Hashing Functions

#### F.35.1.1. `digest()`

```
digest(data text, type text) returns bytea
digest(data bytea, type text) returns bytea
```

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in [Table F.24](#).

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

### F.35.1.2. `hmac()`

```
hmac(data text, key text, type text) returns bytea
hmac(data bytea, key bytea, type text) returns bytea
```

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

## F.35.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

[Table F.21](#) lists the algorithms supported by the `crypt()` function.

**Table F.21. Supported Algorithms for `crypt()`**

| Algorithm | Max Password Length | Adaptive? | Salt Bits | Output Length | Description                |
|-----------|---------------------|-----------|-----------|---------------|----------------------------|
| bf        | 72                  | yes       | 128       | 60            | Blowfish-based, variant 2a |
| md5       | unlimited           | no        | 48        | 34            | MD5-based crypt            |
| xdes      | 8                   | yes       | 24        | 20            | Extended DES               |
| des       | 8                   | no        | 12        | 13            | Original UNIX crypt        |

### F.35.2.1. `crypt()`

```
crypt(password text, salt text) returns text
```

Calculates a crypt(3)-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

### F.35.2.2. `gen_salt()`

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter\_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter\_count* parameter is omitted, the default iteration count is used. Allowed values for *iter\_count* depend on the algorithm and are shown in [Table F.22](#).

**Table F.22. Iteration Counts for `crypt()`**

| Algorithm | Default | Min | Max      |
|-----------|---------|-----|----------|
| xdes      | 725     | 1   | 16777215 |
| bf        | 6       | 4   | 31       |

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES `crypt` was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.23](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *iter\_count* parameter of `gen_salt`.

**Table F.23. Hash Algorithm Speeds**

| Algorithm  | Hashes/sec | For [a-z]     | For [A-Za-z0-9] | Duration relative to md5 hash |
|------------|------------|---------------|-----------------|-------------------------------|
| crypt-bf/8 | 1792       | 4 years       | 3927 years      | 100k                          |
| crypt-bf/7 | 3648       | 2 years       | 1929 years      | 50k                           |
| crypt-bf/6 | 7168       | 1 year        | 982 years       | 25k                           |
| crypt-bf/5 | 13504      | 188 days      | 521 years       | 12.5k                         |
| crypt-md5  | 171584     | 15 days       | 41 years        | 1k                            |
| crypt-des  | 23221568   | 157.5 minutes | 108 days        | 7                             |
| sha1       | 37774272   | 90 minutes    | 68 days         | 4                             |
| md5 (hash) | 150085504  | 22.5 minutes  | 17 days         | 1                             |

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5` hash numbers are from `mdcrack` 1.2.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

### F.35.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

#### F.35.3.1. `pgp_sym_encrypt()`

`pgp_sym_encrypt(data text, psw text [, options text])` returns `bytea`  
`pgp_sym_encrypt_bytea(data bytea, psw text [, options text])` returns `bytea`

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

#### F.35.3.2. `pgp_sym_decrypt()`

`pgp_sym_decrypt(msg bytea, psw text [, options text])` returns `text`

`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ])` returns `bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

#### **F.35.3.3. `pgp_pub_encrypt()`**

`pgp_pub_encrypt(data text, key bytea [, options text ])` returns `bytea`

`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ])` returns `bytea`

Encrypt `data` with a public PGP key `key`. Giving this function a secret key will produce an error.

The `options` parameter can contain option settings, as described below.

#### **F.35.3.4. `pgp_pub_decrypt()`**

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]])` returns `text`

`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]])` returns `bytea`

Decrypt a public-key-encrypted message. `key` must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in `psw`. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The `options` parameter can contain option settings, as described below.

#### **F.35.3.5. `pgp_key_id()`**

`pgp_key_id(bytea)` returns `text`

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

#### **F.35.3.6. `armor()`, `dearmor()`**

`armor(data bytea [ , keys text[], values text[] ])` returns `text`

`dearmor(data text)` returns `bytea`

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the `keys` and `values` arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

### F.35.3.7. `pgp_armor_headers`

`pgp_armor_headers(data text, key out text, value out text)` returns setof record

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

### F.35.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

```
pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')
```

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

#### F.35.3.8.1. `cipher-algo`

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)

Default: aes128

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.35.3.8.2. `compress-algo`

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.35.3.8.3. `compress-level`

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### F.35.3.8.4. `convert-crlf`

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

#### F.35.3.8.5. `disable-mdc`

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent `gnupg.org` and `pgp.com` software supports it fine.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

#### **F.35.3.8.6. sess-key**

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`

#### **F.35.3.8.7. s2k-mode**

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: `pgp_sym_encrypt`

#### **F.35.3.8.8. s2k-count**

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: `pgp_sym_encrypt`, only with `s2k-mode=3`

#### **F.35.3.8.9. s2k-digest-algo**

Which digest algorithm to use in S2K calculation.

Values: `md5`, `sha1`

Default: `sha1`

Applies to: `pgp_sym_encrypt`

#### **F.35.3.8.10. s2k-cipher-algo**

Which cipher to use for encrypting separate session key.

Values: `bf`, `aes`, `aes128`, `aes192`, `aes256`

Default: `use cipher-algo`

Applies to: `pgp_sym_encrypt`

#### **F.35.3.8.11. unicode-mode**

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

### **F.35.3.9. Generating PGP Keys with GnuPG**

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, [The GNU Privacy Handbook](https://www.gnu.org/) and other documentation on <https://www.gnupg.org/>.

### F.35.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

### F.35.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea  
decrypt(data bytea, key bytea, type text) returns bytea
```

```
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea  
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- `bf` — Blowfish
- `aes` — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- `cbc` — next block depends on previous (default)

- `ecb` — each block is encrypted separately (for testing only)

and `padding` is one of:

- `pkcs` — data may be any length (default)
- `none` — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the `iv` parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

## F.35.5. Random-Data Functions

`gen_random_bytes(count integer)` returns `bytea`

Returns `count` cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns `uuid`

Returns a version 4 (random) UUID.

## F.35.6. Notes

### F.35.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

When compiled with `OpenSSL`, there will be more algorithms available. Also public-key encryption functions will be faster as `OpenSSL` has more optimized `BIGNUM` functions.

**Table F.24. Summary of Functionality with and without OpenSSL**

| Functionality             | Built-in | With OpenSSL |
|---------------------------|----------|--------------|
| MD5                       | yes      | yes          |
| SHA1                      | yes      | yes          |
| SHA224/256/384/512        | yes      | yes          |
| Other digest algorithms   | no       | yes (Note 1) |
| Blowfish                  | yes      | yes          |
| AES                       | yes      | yes          |
| DES/3DES/CAST5            | no       | yes          |
| Raw encryption            | yes      | yes          |
| PGP Symmetric encryption  | yes      | yes          |
| PGP Public-Key encryption | yes      | yes          |

When compiled against `OpenSSL 3.0.0` and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like `DES` or `Blowfish`.

Notes:

1. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

### F.35.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

### F.35.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist *side-channel attacks*. For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

## F.36. pg\_freespacemap

The `pg_freespacemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

### F.36.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN)` returns `int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

#### Note

The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

### F.36.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
 blkno | avail 
-----+-----
      0 |      0
      1 |      0
      2 |      0
```

```
3 |      32
4 |     704
5 |     704
6 |     704
7 |    1216
8 |     704
9 |     704
10 |     704
11 |     704
12 |     704
13 |     704
14 |     704
15 |     704
16 |     704
17 |     704
18 |     704
19 |    3648
(20 rows)
```

```
postgres=# SELECT * FROM pg_freespace('foo', 7);
pg_freespace
-----
          1216
(1 row)
```

### F.36.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

## F.37. pg\_hint\_plan

### F.37.1. Name

`pg_hint_plan` - controls execution plan with hinting phrases in comment of special form.

### F.37.2. Synopsis

Postgres Pro Enterprise uses cost-based optimizer, which utilizes data statistics, not static rules. The planner (optimizer) estimates costs of each possible execution plans for a SQL statement then the execution plan with the lowest cost finally be executed. The planner does its best to select the best execution plan, but not perfect, since it doesn't count some properties of the data, for example, correlation between columns.

`pg_hint_plan` makes it possible to tweak execution plans using so-called “hints”, which are simple descriptions in the SQL comment of special form.

### F.37.3. Description

#### F.37.3.1. Basic Usage

`pg_hint_plan` reads hinting phrases in a comment of special form given with the target SQL statement. The special form is beginning by the character sequence “/\*+” and ends with “\*/”. Hint phrases consist of hint name and following parameters enclosed in parentheses and delimited by spaces. Each hinting phrases can be delimited by new lines for readability.

In the example below, hash join is selected as the joining method and scanning `pgbench_accounts` by sequential scan method.

```
postgres=# /*+
```

```

postgres=# HashJoin(a b)
postgres=# SeqScan(a)
postgres=# */
postgres=# EXPLAIN SELECT *
postgres=# FROM pgbench_branches b
postgres=# JOIN pgbench_accounts a ON b.bid = a.bid
postgres=# ORDER BY a.aid;

QUERY PLAN
-----
Sort (cost=31465.84..31715.84 rows=100000 width=197)
  Sort Key: a.aid
  -> Hash Join (cost=1.02..4016.02 rows=100000 width=197)
    Hash Cond: (a.bid = b.bid)
    -> Seq Scan on pgbench_accounts a (cost=0.00..2640.00 rows=100000 width=97)
    -> Hash (cost=1.01..1.01 rows=1 width=100)
      -> Seq Scan on pgbench_branches b (cost=0.00..1.01 rows=1 width=100)
(7 rows)

postgres=#

```

### F.37.4. The hint table

The above section mentions that hints are described in a comment of a special form. This is inconvenient if queries cannot be edited. For such cases, hints can be placed in a special table called `hint_plan.hints`. The table consists of the following columns:

| Column            | Description                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id                | Unique number to identify a row for a hint. This column is filled automatically by sequence.                                                                                                                                  |
| norm_query_string | A pattern that matches the query to be hinted. Constants in the query have to be replaced with ? as in the example below. Whitespace is significant in the pattern.                                                           |
| application_name  | The value of <i>application_name</i> of sessions to apply the hint to. The hint in the example below applies to sessions connected from <code>psql</code> . An empty string means sessions with any <i>application_name</i> . |
| hint              | Hint phrase. This must be a series of hints excluding surrounding comment marks.                                                                                                                                              |

The following example shows how to operate with the hint table.

```

postgres=# INSERT INTO hint_plan.hints(norm_query_string, application_name, hints)
postgres=# VALUES (
postgres=# 'EXPLAIN (COSTS false) SELECT * FROM t1 WHERE t1.id = ?;',
postgres=# 'psql',
postgres=# 'SeqScan(t1) '
postgres=# );
INSERT 0 1
postgres=# UPDATE hint_plan.hints
postgres=# SET hints = 'IndexScan(t1) '
postgres=# WHERE id = 1;
UPDATE 1
postgres=# DELETE FROM hint_plan.hints
postgres=# WHERE id = 1;
DELETE 1

```

```
postgres=#
```

The hint table is owned by the creator user and has the default privileges at the time of creation, during `CREATE EXTENSION`. Table hints are prioritized than comment hints.

### F.37.4.1. The types of hints

Hinting phrases are classified into six types based on the kind of object and how they can affect planning: scanning methods, join methods, joining order, row number correction, parallel query, and GUC setting. You will see the lists of hint phrases of each type in Hint list (See [Section F.37.10](#)).

#### F.37.4.1.1. Hints for scan methods

Scan method hints enforce specific scanning method on the target table. `pg_hint_plan` recognizes the target table by alias names, if any. In this kind of hint, they are “SeqScan”, “IndexScan”, and so on.

Scan hints are effective on ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables and system catalogs. External (foreign) tables, table functions, `VALUES` clause, CTEs, views and subqueries are not affected.

```
postgres=# /*+
postgres*#      SeqScan(t1)
postgres*#      IndexScan(t2 t2_pkey)
postgres*#      */
postgres=# SELECT * FROM table1 t1 JOIN table table2 t2 ON (t1.key = t2.key);
```

#### F.37.4.1.2. Hints for join methods

Join method hints enforce the join methods of the joins involving the specified tables.

This can affect joins only on ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables, external (foreign) tables, system catalogs, table functions, `VALUES` command results, and CTEs. But joins on views and subqueries are not affected.

#### F.37.4.1.3. Hint for joining order

The “Leading” hint enforces the order of join on two or more tables. There are two ways of enforcing. One is enforcing specific order of joining but not restricting direction at each join level:

```
postgres=# /*+
postgres*#      NestLoop(t1 t2)
postgres*#      MergeJoin(t1 t2 t3)
postgres*#      Leading(t1 t2 t3)
postgres*#      */
postgres=# SELECT * FROM table1 t1
postgres=#      JOIN table table2 t2 ON (t1.key = t2.key)
postgres=#      JOIN table table3 t3 ON (t2.key = t3.key);
```

Another way also enforces join direction. When the above join order is specified, the join direction chosen by the planner (outer table — inner table) may be different from the expected one. If you want to change the join direction in such a situation, use the following format:

```
postgres=# / * + Leading ((t1 (t2 t3))) * / SELECT ...
```

In this format, two elements enclosed in parentheses are nested, and within one parenthesis, the first element is the outer table, and the second element is the inner table.

For details, see [Section F.37.10](#).

#### F.37.4.1.4. Hint for row number correction

The “Rows” hint corrects row number misestimation of joins that comes from restrictions of the planner.

```
postgres=# /*+ Rows(a b #10) */ SELECT... ; Sets rows of join result to 10
postgres=# /*+ Rows(a b +10) */ SELECT... ; Increments row number by 10
```

```
postgres=# /*+ Rows(a b -10) */ SELECT... ; Subtracts 10 from the row number.
postgres=# /*+ Rows(a b *10) */ SELECT... ; Makes the number 10 times larger.
```

#### F.37.4.1.5. Hint for parallel plan

The “Parallel” hint enforces parallel execution configuration on scans. The third parameter specifies the strength of enforcement. “soft” means that `pg_hint_plan` only changes `max_parallel_workers_per_gather` and leaves all others to the planner. “hard” changes other planner parameters so as to forcibly apply the number. This can affect ordinary tables, inheritance parents, unlogged tables and system catalog. External tables, table functions, `VALUES` clause, CTEs, views and subqueries are not affected. Internal tables of a view can be specified by its real name/alias as the target object. The following example shows that the query is enforced differently on each table.

```
postgres=# explain /*+ Parallel(c1 3 hard) Parallel(c2 5 hard) */
          SELECT c2.a FROM c1 JOIN c2 ON (c1.a = c2.a);
          QUERY PLAN
-----
Hash Join  (cost=2.86..11406.38 rows=101 width=4)
  Hash Cond: (c1.a = c2.a)
    -> Gather  (cost=0.00..7652.13 rows=1000101 width=4)
        Workers Planned: 3
        -> Parallel Seq Scan on c1  (cost=0.00..7652.13 rows=322613 width=4)
    -> Hash  (cost=1.59..1.59 rows=101 width=4)
        -> Gather  (cost=0.00..1.59 rows=101 width=4)
            Workers Planned: 5
            -> Parallel Seq Scan on c2  (cost=0.00..1.59 rows=59 width=4)

postgres=# EXPLAIN /*+ Parallel(t1 5 hard) */ SELECT sum(a) FROM t1;
          QUERY PLAN
-----
Finalize Aggregate  (cost=693.02..693.03 rows=1 width=8)
  -> Gather  (cost=693.00..693.01 rows=5 width=8)
      Workers Planned: 5
      -> Partial Aggregate  (cost=693.00..693.01 rows=1 width=8)
          -> Parallel Seq Scan on t1  (cost=0.00..643.00 rows=20000 width=4)
```

#### F.37.4.1.6. GUC parameters temporarily setting

“Set” hint changes GUC parameters just while planning. GUC parameter shown in [Section 19.7.2](#) can have the expected effects on planning unless any other hint conflicts with the planner method configuration parameters. The last one among hints on the same GUC parameter makes effect. GUC parameters for `pg_hint_plan` are also settable by this hint but it won't work as you expect.

```
postgres=# /*+ Set(random_page_cost 2.0) */
postgres=# SELECT * FROM table1 t1 WHERE key = 'value';
...
```

#### F.37.4.2. GUC parameters for pg\_hint\_plan

GUC parameters described below affect the behavior of `pg_hint_plan`.

**Table F.25. GUC Parameters**

| Parameter Name                              | Description                                                                                             | Default Value |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------|---------------|
| <code>pg_hint_plan.enable_hint</code>       | True enables <code>pg_hint_plan</code> .                                                                | on            |
| <code>pg_hint_plan.enable_hint_table</code> | True enables hinting by table.                                                                          | on            |
| <code>pg_hint_plan.parse_messages</code>    | Specifies the log level of hint parse error. Valid values are error, warning, notice, info, log, debug. | INFO          |

| Parameter Name             | Description                                                                                                                                                                            | Default Value     |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| pg_hint_plan.debug_print   | Controls debug print and verbosity. Valid values are <code>off</code> , <code>on</code> , <code>detailed</code> , and <code>verbose</code> .                                           | <code>off</code>  |
| pg_hint_plan.message_level | Specifies message level of debug print. Valid values are <code>error</code> , <code>warning</code> , <code>notice</code> , <code>info</code> , <code>log</code> , <code>debug</code> . | <code>INFO</code> |

## F.37.5. Installation

Basically `pg_hint_plan` does not require `CREATE EXTENSION`. Simply loading it by `LOAD` command will activate it and of course you can load it globally by setting `shared_preload_libraries` in `postgresql.conf`. Or you might be interested in `ALTER USER SET/ALTER DATABASE SET` for automatic loading for specific sessions.

```
postgres=# LOAD 'pg_hint_plan';
LOAD
postgres=#
```

Do `CREATE EXTENSION` and `SET pg_hint_plan.enable_hint_table TO on` if you are planning to use hint table.

## F.37.6. Details in hinting

### F.37.6.1. Syntax and placement

`pg_hint_plan` reads hints from only the first block comment and any characters except alphabets, digits, spaces, underscores, commas and parentheses stop parsing immediately. In the following example `HashJoin(a b)` and `SeqScan(a)` are parsed as hints, but `IndexScan(a)` and `MergeJoin(a b)` are not.

```
postgres=# /*+
postgres*#      HashJoin(a b)
postgres*#      SeqScan(a)
postgres*#    */
postgres-# /*+ IndexScan(a) */
postgres-# EXPLAIN SELECT /*+ MergeJoin(a b) */ *
postgres-#      FROM pgbench_branches b
postgres-#      JOIN pgbench_accounts a ON b.bid = a.bid
postgres-#      ORDER BY a.aid;
```

QUERY PLAN

```
-----
Sort  (cost=31465.84..31715.84 rows=100000 width=197)
@@ -237,17 +285,56 @@ postgres-#      ORDER BY a.aid;
(7 rows)
```

```
postgres=#
```

### F.37.6.2. Using with PL/pgSQL

`pg_hint_plan` works for queries in PL/pgSQL scripts with some restrictions.

- Hints affect only the following kinds of queries:
  - Queries that return one row. (`SELECT`, `INSERT`, `UPDATE`, and `DELETE`)
  - Queries that return multiple rows. (`RETURN QUERY`)
  - Dynamic SQL statements. (`EXECUTE`)
  - Cursor open. (`OPEN`)

- Loop over result of a query (FOR)
- A hint comment have to be placed after the first word in a query as the following since preceding comments are not sent as a part of the query.

```
postgres=# CREATE FUNCTION hints_func(integer) RETURNS integer AS $$
postgres$# DECLARE
postgres$#     id integer;
postgres$#     cnt integer;
postgres$# BEGIN
postgres$#     SELECT /*+ NoIndexScan(a) */ aid
postgres$#         INTO id FROM pgbench_accounts a WHERE aid = $1;
postgres$#     SELECT /*+ SeqScan(a) */ count(*)
postgres$#         INTO cnt FROM pgbench_accounts a;
postgres$#     RETURN id + cnt;
postgres$# END;
postgres$# $$ LANGUAGE plpgsql;
```

### F.37.6.3. Letter case in object names

Unlike the way PostgreSQL handles object names, `pg_hint_plan` compares bare object names in hints against the database internal object names in a case-sensitive way. Therefore, an object name `TBL` in a hint matches only “TBL” in database and does not match any unquoted names like `TBL`, `tbl`, or `Tbl`.

### F.37.6.4. Escaping special characters in object names

The objects as the hint parameter should be enclosed in double quotes if they includes parentheses, double quotes, and white spaces. The escaping rule is the same as in PostgreSQL.

### F.37.6.5. Distinction between multiple occurrences of a table

`pg_hint_plan` identifies the target object by using aliases if exists. This behavior is usable to point a specific occurrence among multiple occurrences of one table.

```
postgres=# /*+ HashJoin(t1 t1) */
postgres=# EXPLAIN SELECT * FROM s1.t1
postgres=# JOIN public.t1 ON (s1.t1.id=public.t1.id);
INFO:  hint syntax error at or near "HashJoin(t1 t1)"
DETAIL:  Relation name "t1" is ambiguous.
...
postgres=# /*+ HashJoin(pt st) */
postgres=# EXPLAIN SELECT * FROM s1.t1 st
postgres=# JOIN public.t1 pt ON (st.id=pt.id);
               QUERY PLAN

-----
Hash Join  (cost=64.00..1112.00 rows=28800 width=8)
  Hash Cond: (st.id = pt.id)
    -> Seq Scan on t1 st  (cost=0.00..34.00 rows=2400 width=4)
    -> Hash  (cost=34.00..34.00 rows=2400 width=4)
         -> Seq Scan on t1 pt  (cost=0.00..34.00 rows=2400 width=4)
```

### F.37.6.6. Underlying tables of views or rules

Hints are not applicable on views itself, but they can affect the queries within if the object names match the object names in the expanded query on the view. Assigning aliases to the tables in a view enables them to be manipulated from outside of the view.

```
postgres=# CREATE VIEW v1 AS SELECT * FROM t2;
postgres=# EXPLAIN /*+ HashJoin(t1 v1) */
           SELECT * FROM t1 JOIN v1 ON (c1.a = v1.a);
               QUERY PLAN
-----
```

```
Hash Join (cost=3.27..18181.67 rows=101 width=8)
  Hash Cond: (t1.a = t2.a)
  -> Seq Scan on t1 (cost=0.00..14427.01 rows=1000101 width=4)
  -> Hash (cost=2.01..2.01 rows=101 width=4)
      -> Seq Scan on t2 (cost=0.00..2.01 rows=101 width=4)
```

### F.37.6.7. Inheritance tables

Hints can point only the parent of inheritance tables and the hint affect all the inheritance. Hints simultaneously point directly to children are not in effect.

### F.37.6.8. Hinting on multistatements

One multistatement can have exactly one hint comment and the hint affects all of the individual statements in the multistatement. Notice that the seemingly multistatement on the interactive interface of `psql` is internally a sequence of single statements so hints affect only the statement just following.

### F.37.6.9. VALUES expressions

`VALUES` expressions in the `FROM` clause are named as “\*VALUES\*” internally so it is hintable if it is the only `VALUES` in a query. Two or more `VALUES` expressions in a query seems distinguishable looking its explain result. But in reality it is mere a cosmetic and they are not distinguishable.

```
postgres=# /*+ MergeJoin(*VALUES*_1 *VALUES*) */
EXPLAIN SELECT * FROM (VALUES (1, 1), (2, 2)) v (a, b)
JOIN (VALUES (1, 5), (2, 8), (3, 4)) w (a, c) ON v.a = w.a;
INFO:  pg_hint_plan: hint syntax error at or near "MergeJoin(*VALUES*_1 *VALUES*)"
DETAIL:  Relation name "*VALUES*" is ambiguous.
          QUERY PLAN

-----
Hash Join (cost=0.05..0.12 rows=2 width=16)
  Hash Cond: ("*VALUES*_1".column1 = "*VALUES*".column1)
  -> Values Scan on "*VALUES*_1" (cost=0.00..0.04 rows=3 width=8)
  -> Hash (cost=0.03..0.03 rows=2 width=8)
      -> Values Scan on "*VALUES*" (cost=0.00..0.03 rows=2 width=8)
```

## F.37.7. Subqueries

Subqueries in the following context occasionally can be hinted using the name “ANY\_subquery”.

```
IN (SELECT ... {LIMIT | OFFSET ...} ...)
= ANY (SELECT ... {LIMIT | OFFSET ...} ...)
= SOME (SELECT ... {LIMIT | OFFSET ...} ...)
```

For these syntaxes, planner internally assigns the name to the subquery when planning joins on tables including it, so join hints are applicable on such joins using the implicit name as follows:

```
postgres=# /*+HashJoin(a1 ANY_subquery)*/
postgres=# EXPLAIN SELECT *
postgres=#   FROM pgbench_accounts a1
postgres=#   WHERE aid IN (SELECT bid FROM pgbench_accounts a2 LIMIT 10);
          QUERY PLAN

-----
Hash Semi Join (cost=0.49..2903.00 rows=1 width=97)
  Hash Cond: (a1.aid = a2.bid)
  -> Seq Scan on pgbench_accounts a1 (cost=0.00..2640.00 rows=100000 width=97)
  -> Hash (cost=0.36..0.36 rows=10 width=4)
      -> Limit (cost=0.00..0.26 rows=10 width=4)
          -> Seq Scan on pgbench_accounts a2 (cost=0.00..2640.00 rows=100000
width=4)
```

### F.37.7.1. Using IndexOnlyScan hint

Index scan may be unexpectedly performed on another index when the index specified in IndexOnlyScan hint cannot perform index-only scan.

### F.37.7.2. Behavior of NoIndexScan

NoIndexScan hint involves NoIndexOnlyScan.

### F.37.7.3. Parallel hint and UNION

A UNION can run in parallel only when all underlying subqueries are parallel-safe. Conversely, enforcing parallel on any of the subqueries lets a parallel-executable UNION run in parallel. Meanwhile, a parallel hint with zero workers inhibits a scan from being executed in parallel.

### F.37.7.4. Setting pg\_hint\_plan parameters by Set hints

pg\_hint\_plan parameters change the behavior of itself so some parameters do not work as expected.

- Hints to change `enable_hint`, `enable_hint_table` are ignored even though they are reported as “used hints” in debug logs.
- Setting `debug_print` and `message_level` works from midst of the processing of the target query.

## F.37.8. Errors

pg\_hint\_plan stops parsing on any error and uses hints already parsed on the most cases. Followings are the typical errors.

### F.37.8.1. Syntax errors

Any syntactical errors or wrong hint names are reported as an syntax error. These errors are reported in the server log with the message level which specified by `pg_hint_plan.message_level` if `pg_hint_plan.debug_print` is on or above.

### F.37.8.2. Object misspecifications

Object misspecifications results silent ignorance of the hints. This kind of error is reported as “not used hints” in the server log by the same condition to syntax errors.

### F.37.8.3. Redundant or conflicting hints

The last hint will be active when redundant hints or hints conflicting with each other. This kind of error is reported as “duplication hints” in the server log by the same condition to syntax errors.

### F.37.8.4. Nested comments

Hint comment cannot include another block comment within. If pg\_hint\_plan finds it, differently from other errors, it stops parsing and abandons all hints already parsed. This kind of error is reported in the same manner as other errors.

## F.37.9. Functional limitations

### F.37.9.1. Influences of some of planner GUC parameters

The planner does not try to consider joining order for FROM clause entries more than `from_collapse_limit`. pg\_hint\_plan cannot affect joining order as expected for the case.

### F.37.9.2. Hints trying to enforce inexecutable plans

Planner chooses any executable plans when the enforced plan cannot be executed.

- FULL OUTER JOIN to use nested loop
- To use indexes that does not have columns used in quals
- To do TID scans for queries without ctid conditions

### F.37.9.3. Queries in ECPG

ECPG removes comments in queries written as embedded SQL so hints cannot be passed from those queries. The only exception is that EXECUTE command passes given string unmodified. Please consider hint tables for this case.

### F.37.9.4. Work with pg\_stat\_statements

pg\_stat\_statements generates a query ID ignoring comments. As the result, the identical queries with different hints are summarized as the same query.

## F.37.10. Available Hints

The available hints are listed below.

**Table F.26. Hints list**

| Group       | Format                                                        | Description                                                                                                                             |
|-------------|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Scan method | SeqScan( <i>table</i> )                                       | Forces sequential scan on the table.                                                                                                    |
|             | TidScan( <i>table</i> )                                       | Forces TID scan on the table.                                                                                                           |
|             | IndexScan( <i>table</i> [ <i>index</i> ...])                  | Forces index scan on the table. Restricts to specified indexes if any.                                                                  |
|             | IndexOnlyScan( <i>table</i> [ <i>index</i> ...])              | Forces index only scan on the table. Restricts to specified indexes if any. Index scan may be used if index only scan is not available. |
|             | BitmapScan( <i>table</i> [ <i>index</i> ...])                 | Forces bitmap scan on the table. Restricts to specified indexes if any.                                                                 |
|             | IndexScanRegexp( <i>table</i> [ <i>POSIX regexp</i> ...])     | Forces index scan on the table. Restricts to indexes that match the specified <a href="#">POSIX regular expression</a> .                |
|             | IndexOnlyScanRegexp( <i>table</i> [ <i>POSIX regexp</i> ...]) | Forces index only scan on the table. Restricts to indexes that match the specified <a href="#">POSIX regular expression</a> .           |
|             | BitmapScanRegexp( <i>table</i> [ <i>POSIX regexp</i> ...])    | Forces bitmap scan on the table. Restricts to indexes that match the specified <a href="#">POSIX regular expression</a> .               |
|             | NoSeqScan( <i>table</i> )                                     | Forces not to do sequential scan on the table.                                                                                          |
|             | NoTidScan( <i>table</i> )                                     | Forces not to do TID scan on the table.                                                                                                 |
|             | NoIndexScan( <i>table</i> )                                   | Forces not to do index scan and index only scan on the table.                                                                           |
|             | NoIndexOnlyScan( <i>table</i> )                               | Forces not to do index only scan on the table.                                                                                          |
|             | NoBitmapScan( <i>table</i> )                                  | Forces not to do bitmap scan on the table.                                                                                              |
| Join method | NestLoop( <i>table table</i> [ <i>table</i> ...])             | Forces nested loop for the joins with the specified tables.                                                                             |

| Group                        | Format                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              | <code>HashJoin(table table[ table...])</code>                 | Forces hash join for the joins with the specified tables.                                                                                                                                                                                                                                                                                                                                                                       |
|                              | <code>MergeJoin(table table[ table...])</code>                | Forces merge join for the joins with the specified tables.                                                                                                                                                                                                                                                                                                                                                                      |
|                              | <code>NoNestLoop(table table[ table...])</code>               | Forces not to do nested loop for the joins with the specified tables.                                                                                                                                                                                                                                                                                                                                                           |
|                              | <code>NoHashJoin(table table[ table...])</code>               | Forces not to do hash join for the joins with the specified tables.                                                                                                                                                                                                                                                                                                                                                             |
|                              | <code>NoMergeJoin(table table[ table...])</code>              | Forces not to do merge join for the joins with the specified tables.                                                                                                                                                                                                                                                                                                                                                            |
| Join order                   | <code>Leading(table table[ table...])</code>                  | Forces join order as specified.                                                                                                                                                                                                                                                                                                                                                                                                 |
|                              | <code>Leading(&lt;join pair&gt;)</code>                       | Forces join order and directions as specified. A join pair is a pair of tables and/or other join pairs enclosed in parentheses, which can make a nested structure.                                                                                                                                                                                                                                                              |
| Row number correction        | <code>Rows(table table[ table...] correction)</code>          | Corrects row number of a result of the joins with the specified tables. The available correction methods are absolute ( <code>#&lt;n&gt;</code> ), addition ( <code>+&lt;n&gt;</code> ), subtraction ( <code>-&lt;n&gt;</code> ) and multiplication ( <code>*&lt;n&gt;</code> ). <code>&lt;n&gt;</code> should be a string that <code>strtod()</code> can read.                                                                 |
| Parallel query configuration | <code>Parallel(table &lt;# of workers&gt; [soft hard])</code> | Enforce or inhibit parallel execution of the specified table. <code>&lt;# of workers&gt;</code> is the desired number of parallel workers, where zero means inhibiting parallel execution. If the third parameter is <code>soft</code> (default), it just changes <code>max_parallel_workers_per_gather</code> and leaves everything else to the planner. The <code>hard</code> value enforces the specified number of workers. |
| GUC                          | <code>Set(GUC-parameter value)</code>                         | Set the GUC parameter to the value while planner is running.                                                                                                                                                                                                                                                                                                                                                                    |

## F.38. pg\_pathman

The `pg_pathman` is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using `pg_pathman`, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.

- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

### F.38.1. Installation and Setup

The `pg_pathman` extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable `pg_pathman`:

1. Add `pg_pathman` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_pathman'
```

#### Important

`pg_pathman` may have conflicts with other extensions that use the same hook functions. For example, `pg_pathman` may interfere with the `pg_stat_statements` extension as they both use `ProcessUtility_hook`. To avoid such issues, `pg_pathman` must always be the last in the list of libraries: `shared_preload_libraries = 'pg_stat_statements, pg_pathman'`

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the `pg_pathman` extension as follows:

```
CREATE SCHEMA pathman;  
GRANT USAGE ON SCHEMA pathman TO PUBLIC;  
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

#### Important

To ensure that your calls to `pg_pathman`'s functions are always secure against `search_path`-based attacks (see [CREATE EXTENSION](#) for details), install it only into a clean schema where nobody except superusers has the `CREATE` privilege for database objects.

Once `pg_pathman` is enabled, you can start partitioning tables.

#### Note

During installation, `pg_pathman` creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing `CREATE POLICY` statements are installed. Therefore, when restoring a dump of a database where `pg_pathman` is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

#### Tip

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see [Building and Installing PostgreSQL Extension Modules](#).

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see [Section F.38.5.1](#).

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

### F.38.1.1. Updating `pg_pathman`

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;  
SET pg_pathman.enable = t;
```

where *version* is the `pg_pathman` major version number, such as 1.5.

You can check the current `pg_pathman` version by running the `pathman_version()` function.

## F.38.2. Usage

[Choosing Partitioning Strategies](#)

[Running Non-Blocking Data Migration](#)

[Partitioning by a Single Expression](#)

[Partitioning by Composite Key](#)

[Running Multilevel Partitioning](#)

[Using Declarative Syntax](#)

[Managing Partitions](#)

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for [declarative partitioning](#) was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see [Section F.38.4](#).

### F.38.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- **Hash** — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- **Range** — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see [Section F.38.2.2](#).

#### F.38.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid    REGCLASS,
                      expression      TEXT,
                      partitions_count INTEGER,
                      partition_data   BOOLEAN DEFAULT TRUE,
                      partition_names  TEXT[]  DEFAULT NULL,
                      tablespaces     TEXT[]  DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition  REGCLASS,
                      new_partition   REGCLASS,
                      lock_parent     BOOL DEFAULT TRUE);
```

When set to `true`, `lock_parent` parameter will prevent any `INSERT/UPDATE/ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.38.2.2](#).

#### F.38.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid  REGCLASS,
                      expression      TEXT,
                      start_value     ANYELEMENT,
                      p_interval      ANYELEMENT | INTERVAL,
                      p_count         INTEGER DEFAULT NULL,
                      partition_data  BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid    REGCLASS,  
                        expression      TEXT,  
                        bounds          ANYARRAY,  
                        partition_names TEXT[] DEFAULT NULL,  
                        tablespaces     TEXT[] DEFAULT NULL,  
                        partition_data  BOOLEAN DEFAULT TRUE)
```

If required, you can also use [partition management functions](#) to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.38.2.2](#).

### F.38.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation    REGCLASS,  
                             batch_size  INTEGER DEFAULT 1000,  
                             sleep_time  FLOAT8 DEFAULT 1.0)
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;  
userid | pid  | dbid  | relid | processed | status  
-----+-----+-----+-----+-----+-----  
user   | 20012 | 12413 | test  | 334000    | working  
(1 row)
```

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

**Tip**

When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

**F.38.2.3. Partitioning by a Single Expression**

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

**Tip**

If you would like to partition a table by a tuple, see [Section F.38.2.4](#).

To partition a table by expression, use `pg_pathman` [partitioning functions](#). The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as `NOT NULL`.
- Expression cannot reference system attributes, such as `oid`, `xmin`, `xmax`, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as `IMMUTABLE`.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, `pg_pathman` cannot optimize the query. You can view the partitioning expression for each partitioned table in the `pathman_config` table.

**F.38.2.3.1. Examples**

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
             i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the `key` value, you need to extract this value from the `jsonb` object and convert it to a numeric type, such as `bigint`:

```
SELECT create_range_partitions('test', '(col->>'key')::bigint', 1, 10000, 10);
```

`pg_pathman` splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
```

| parent | partition | parttype | expr                            | range_min | range_max |
|--------|-----------|----------|---------------------------------|-----------|-----------|
| test   | test_1    | 2        | ((col ->> 'key')::text)::bigint | 1         | 10001     |
| test   | test_2    | 2        | ((col ->> 'key')::text)::bigint | 10001     | 20001     |
| test   | test_3    | 2        | ((col ->> 'key')::text)::bigint | 20001     | 30001     |
| test   | test_4    | 2        | ((col ->> 'key')::text)::bigint | 30001     | 40001     |
| test   | test_5    | 2        | ((col ->> 'key')::text)::bigint | 40001     | 50001     |
| test   | test_6    | 2        | ((col ->> 'key')::text)::bigint | 50001     | 60001     |
| test   | test_7    | 2        | ((col ->> 'key')::text)::bigint | 60001     | 70001     |

```
test      | test_8      |          2 | ((col ->> 'key'::text))::bigint | 70001      | 80001
test      | test_9      |          2 | ((col ->> 'key'::text))::bigint | 80001      | 90001
test      | test_10     |          2 | ((col ->> 'key'::text))::bigint | 90001      | 100001
(10 rows)
```

#### F.38.2.4. Partitioning by Composite Key

Using `pg_pathman`, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in [Section F.38.2.3](#).

Although `pg_pathman` does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

##### F.38.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
                               extract(month from logdate) )::test_key',
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
                           (extract(year from current_date), 1)::test_key,
                           (extract(year from current_date + '10 years'::interval),
                             1)::test_key);
```

#### F.38.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in [Section F.38.2.1](#), passing the name of the partition to be split as the `parent_relid` parameter. You can check the exact partition names in the [pathman\\_partition\\_list](#) view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is

larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

#### F.38.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table
CREATE TABLE journal (
  id      SERIAL,
  dt      TIMESTAMP NOT NULL,
  level   INTEGER,
  msg     TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1
  month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1
  day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

#### F.38.2.6. Using Declarative Syntax

Declarative syntax for partitioning enables you to define the partitioning strategy when creating a table, as well as partition existing tables and manage table partitions using SQL commands. Postgres Pro Enterprise offers the following implementations of declarative syntax:

- Postgres Pro core functionality, described in detail in [Section 5.10.2](#).
- `pg_pathman` implementation of declarative syntax.

Depending on the chosen implementation, the available SQL command forms will differ, as explained in [CREATE TABLE](#) and [ALTER TABLE](#) descriptions.

By default, Postgres Pro core functionality is used for declarative partitioning. To enable declarative partitioning provided by `pg_pathman`, set the [partition\\_backend](#) parameter to the `pg_pathman` value. In this case, you can use declarative range and hash partitioning strategies as explained below. For the [CREATE TABLE](#) command, you can also override the [partition\\_backend](#) setting by specifying the `USING partition_backend` clause.

When running the `CREATE TABLE` command, you can use the `PARTITION BY` clause to split the resulting table into partitions by range or hash.

To create a table partitioned by range, specify the partition names, the range of values to include into each partition and, optionally, a tablespace. For example:

```
CREATE TABLE abc(id serial NOT NULL)
  PARTITION BY RANGE(id)
  (
    PARTITION abc_100 VALUES LESS THAN (100) TABLESPACE ts1,
```

```
    PARTITION abc_200 VALUES LESS THAN (200) TABLESPACE ts2
);
```

When creating a table partitioned by hash, you can either specify the number of partitions to create, or the exact partitions and tablespaces. For example, to create the `abc` table with three partitions, run:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY HASH (id) PARTITIONS (3);
```

To define the exact partitions to create, use the following statement:

```
CREATE TABLE abc(id serial NOT NULL)
    PARTITION BY HASH (id)
    (
        PARTITION abc_first TABLESPACE ts1,
        PARTITION abc_second TABLESPACE ts2
    );
```

To partition an already created table, you can use the `ALTER TABLE` command with the `PARTITION BY` clause. For example, to split the `abc` table into three hash partitions, run:

```
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3);
```

When performing range partitioning of an already created table, you have to specify the lower bound of the first partition, which must not be greater than the smallest value in the partition key column, and provide the partitioning interval that defines the range of values to include into a single partition:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (2000);
```

If the table to partition contains a lot of data and it is critical to avoid downtime, consider using the optional `CONCURRENTLY` clause. In this case, `pg_pathman` first creates empty partitions, and then migrates the data in batches of 1000 rows. This clause can be used for both hash and range partitioning. For example:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (50000) CONCURRENTLY;
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3) CONCURRENTLY;
```

`pg_pathman` declarative syntax also supports multilevel partitioning. Once the table is partitioned, you can run the `ALTER TABLE` command with the `PARTITION BY` clause on the partition that you would like to split. Consider the following example with hash partitioning:

```
CREATE TABLE test(a int NOT NULL, b int NOT NULL)
    PARTITION BY by hash(a) PARTITIONS (8);

ALTER TABLE test_1
    PARTITION BY hash(b) PARTITIONS (10);
```

As a result, the `test` table is split into eight hash partitions, and its `test_1` partition is further split into ten partitions by another key.

The `ALTER TABLE` command can also be run with partition management clauses to add, remove, or modify partitions, as explained in [ALTER TABLE](#). You can perform these actions on tables partitioned with `pg_pathman` regardless of the [partition\\_backend](#) setting.

### F.38.2.7. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see [Section F.38.5.3.4](#).

## F.38.3. Examples

### F.38.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.
- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

```
SELECT * FROM pathman_concurrent_part_tasks;
userid | pid | dbid | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 7367 | 16384 | test  | 472000    | working
(1 row)
```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

```
SELECT drop_range_partition(partition, false) /* move data to parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
NOTICE:  1 rows copied from part_test_11
NOTICE: 100 rows copied from part_test_1
NOTICE: 100 rows copied from part_test_2
drop_range_partition
-----
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

### F.38.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id          SERIAL PRIMARY KEY,
name        TEXT,
code        BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
 id | name | code
----+-----+-----
1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
```

(1 row)

```
EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
```

```
-----
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
Index Cond: (id = 1234)
```

Notice that the Append node contains only one child scan, which corresponds to the WHERE clause.

### Important

Pay attention to the fact that pg\_pathman excludes the parent table from the query plan.

To access the parent table, use the ONLY modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
```

```
-----
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

#### F.38.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);

-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;

SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
'2015-01-01'::date);
```

### Important

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |          dt          | level |          msg
-----+-----+-----+-----
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)

EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
-----
Append  (cost=0.00..58.80 rows=0 width=0)
->  Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
->  Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

## F.38.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

### F.38.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionRouter` for cross-partition `UPDATE` queries instead of triggers

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
      QUERY PLAN
-----
Insert on partitioned_table
-> Custom Scan (PartitionFilter)
    -> Subquery Scan on "*SELECT*"
        -> Result

(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

#### Important

The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE + INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to on.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
      QUERY PLAN
-----
Update on partitioned_table_0
-> Custom Scan (PartitionRouter)
    -> Custom Scan (PartitionFilter)
        -> Seq Scan on partitioned_table_0
            Filter: (value = 2)

(5 rows)
```

`RuntimeAppend` and `RuntimeMergeAppend` have much in common: they come in handy in a case when `WHERE` condition takes form of:

```
VARIABLE OP PARAM
```

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original `Append`'s code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

- id = (select ... limit 1)

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
rows=1 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)
```

```
/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)

```

- NestLoop **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's [blog](#).

## F.38.5. Reference

### F.38.5.1. GUC Variables

There are several user-accessible [GUC](#) variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

Default: on

- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_runtime_merge_append` — toggle the `RuntimeMergeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

Default: on

- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

Default: off

- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

Default: on

- `pg_pathman.insert_into_fdw` — allow `INSERT` operations into various foreign-data wrappers. Possible values: `disabled`, `postgres`, and `any_fdw`.

Default: `postgres`

- `pg_pathman.override_copy` — toggle `COPY` statement hooking on/off.

Default: on

## F.38.5.2. Views and Tables

### F.38.5.2.1. `pathman_config`

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    attname          TEXT NOT NULL,  
    parttype         INTEGER NOT NULL,  
    range_interval   TEXT);
```

### F.38.5.2.2. `pathman_config_params`

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,  
    auto             BOOLEAN NOT NULL DEFAULT TRUE,  
    init_callback    REGPROCEDURE NOT NULL DEFAULT 0,  
    spawn_using_bgw  BOOLEAN NOT NULL DEFAULT FALSE);
```

### F.38.5.2.3. `pathman_concurrent_part_tasks`

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function  
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()  
RETURNS TABLE (  
    userid          REGROLE,  
    pid             INT,  
    dbid            OID,  
    relid           REGCLASS,
```

```
    processed INT,
    status    TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;
```

```
CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

#### F.38.5.2.4. pathman\_partition\_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent      REGCLASS,
    partition   REGCLASS,
    parttype    INT4,
    expr        TEXT,
    range_min   TEXT,
    range_max   TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;
```

```
CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

### F.38.5.3. Functions

#### F.38.5.3.1. Partitioning Functions

```
create_hash_partitions(parent_relid      REGCLASS,
                       expression        TEXT,
                       partitions_count  INTEGER,
                       partition_data    BOOLEAN DEFAULT TRUE,
                       partition_names   TEXT[]  DEFAULT NULL,
                       tablespaces      TEXT[]  DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is `true`, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation         REGCLASS,
                       expression        TEXT,
                       start_value       ANYELEMENT,
                       p_interval        ANYELEMENT,
                       p_count           INTEGER DEFAULT NULL,
                       partition_data    BOOLEAN DEFAULT TRUE)

create_range_partitions(relation         REGCLASS,
                       expression        TEXT,
                       start_value       ANYELEMENT,
                       p_interval        INTERVAL,
                       p_count           INTEGER DEFAULT NULL,
                       partition_data    BOOLEAN DEFAULT TRUE)
```

```
create_range_partitions(relation      REGCLASS,  
                       expression    TEXT,  
                       bounds        ANYARRAY,  
                       partition_names TEXT[] DEFAULT NULL,  
                       tablespaces   TEXT[] DEFAULT NULL,  
                       partition_data BOOLEAN DEFAULT TRUE)
```

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

#### F.38.5.3.2. Data Migration Functions

```
partition_table_concurrently(relation REGCLASS,  
                             batch_size INTEGER DEFAULT 1000,  
                             sleep_time FLOAT8 DEFAULT 1.0)
```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```
stop_concurrent_part_task(relation REGCLASS)
```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

#### F.38.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of `BEFORE/AFTER INSERT` trigger functions of a corresponding partition.
- Each updated row results in execution of `BEFORE/AFTER UPDATE` trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of `BEFORE UPDATE + BEFORE/AFTER DELETE + BEFORE/AFTER INSERT` trigger functions of corresponding partitions.

#### F.38.5.3.4. Partition Management Functions

```
replace_hash_partition(old_partition  REGCLASS,  
                       new_partition  REGCLASS,  
                       lock_parent    BOOLEAN DEFAULT TRUE)
```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT/UPDATE/ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid REGCLASS,  
                      split_value     ANYELEMENT,  
                      partition_name   TEXT DEFAULT NULL,  
                      tablespace       TEXT DEFAULT NULL)
```

Split range partition in two by value, with the specified value included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid REGCLASS,  
                      partition_name TEXT DEFAULT NULL,  
                      tablespace TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid REGCLASS,  
                      partition_name TEXT DEFAULT NULL,  
                      tablespace TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid REGCLASS,  
                  start_value ANYELEMENT,  
                  end_value ANYELEMENT,  
                  partition_name TEXT DEFAULT NULL,  
                  tablespace TEXT DEFAULT NULL)
```

Create a new range partition for relation with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid REGCLASS,  
                    partition_relid REGCLASS,  
                    start_value ANYELEMENT,  
                    end_value ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see [Section F.38.5.2.2](#)).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,  
              delete_data BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is false, the data is copied to the parent table first. Default is false.

### F.38.5.3.5. Additional Functions

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
```

```
{
  "parent":      "abc",
  "parttype":    "2",
  "partition":   "abc_4",
  "range_max":   "401",
  "range_min":   "301"
}
```

```
/* Hash-partitioned table abc (child abc_0) */
```

```
{
  "parent":      "abc",
  "parttype":    "1",
  "partition":   "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use `SpawnPartitionsWorker` to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid    REGCLASS,
                      expression      TEXT,
                      range_interval   TEXT)
add_to_pathman_config(parent_relid    REGCLASS,
                      expression      TEXT)
```

Register the specified `relation` table with `pg_pathman` to enable partitioning by the provided `expression`. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start    ANYELEMENT,  
                      p_interval  INTERVAL,  
                      p_count     INTEGER)
```

```
generate_range_bounds(p_start    ANYELEMENT,  
                      p_interval  ANYELEMENT,  
                      p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

- Dmitry Ivanov

## F.39. pg\_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared\\_preload\\_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

### F.39.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',  
           first_block int8 default null,  
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

## F.39.2. Configuration Parameters

`pg_prewarm.autoprewarm` (boolean)

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

`pg_prewarm.autoprewarm_interval` (int)

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

## F.39.3. Author

Robert Haas <رهااس@postgresql.org>

## F.40. pgpro\_scheduler

`pgpro_scheduler` is a built-in Postgres Pro Enterprise extension for scheduling, monitoring, and managing job execution within the Postgres Pro Enterprise database. With `pgpro_scheduler`, you can:

- Set advanced schedules using `jsonb` objects or `crontab` strings.
- Dynamically calculate the next execution time for repeated jobs.
- Execute SQL commands of the job in a single transaction or in sequential transactions, if required.
- Submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs.

Unlike external scheduling daemons, `pgpro_scheduler` offers the following benefits:

- Any user can schedule jobs independently.
- Job scheduling can be managed on the fly without restarting the database.
- Scheduling is very lightweight since `pgpro_scheduler` uses background workers to schedule, monitor, and manage job execution. At the same time, `pgpro_scheduler` does not require any client connections for scheduling.
- For enhanced stability, each database has its own supervisor scheduler, with each scheduled job executed by a separate background worker.

### Note

`pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a master server.

### Note

Note that for all the executed jobs, the `pg_stat_activity` view will still show the name of the database superuser, which is used by the background worker.

### F.40.1. Installation and Setup

The `pgpro_scheduler` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `pgpro_scheduler`:

1. Add `pgpro_scheduler` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_scheduler'
```

2. Create the `pgpro_scheduler` extension using the following query:

```
CREATE EXTENSION pgpro_scheduler;
```

Make sure to create the `pgpro_scheduler` extension for each database you are planning to use.

Once you complete the installation and setup, configure `pgpro_scheduler` for your database.

### F.40.2. Configuration

You must have superuser rights to configure `pgpro_scheduler`.

To configure `pgpro_scheduler`, modify the following settings in the `postgresql.conf` file:

1. Specify the names of the databases for which you need to schedule jobs, in the comma-separated format:

```
schedule.database = 'database1,database2'
```

2. To control the workload in your system, set the maximum number of background workers that can run simultaneously on each database:

```
schedule.max_workers = 5
```

3. Optionally, set the number of background workers available for one-time job execution:

```
schedule.max_parallel_workers = 3
```

By default, two background workers for one-time jobs are available. These workers are not included into the `schedule.max_workers` number. Thus, one-time jobs can run in parallel with the scheduled jobs even if all the `schedule.max_workers` workers are busy.

4. Run `pg_reload_conf()` for the changes to take effect:

```
SELECT pg_reload_conf();
```

#### Important

When setting the `schedule.max_workers` variable, make sure to leave enough workers for the rest of the system as other subsystems may also use background workers. The `schedule.max_workers` value cannot exceed the total number of workers enabled by the `max_worker_processes` Postgres Pro variable.

The `pgpro_scheduler` extension starts a separate background worker for the system, each database, and each executed job. For example, if you work with two databases and set the maximum number of workers and parallel workers to 5 and 3, respectively, `pgpro_scheduler` can use up to 19 workers at peak times: one worker is supervising the system, two workers are monitoring the two databases, and each database uses five workers for job scheduling and three workers for running one-time jobs. If all background workers are busy, the jobs will wait for the next available worker. Scheduled and one-time jobs have separate job queues.

If required, you can later change the number of workers. The running jobs will not be affected.

You can also dynamically configure `pgpro_scheduler` from the command line. In this case, you can set different number of workers for different databases:

```
ALTER SYSTEM SET schedule.database = 'database1,database2';
ALTER DATABASE database1 SET schedule.max_workers = 5;
ALTER DATABASE database2 SET schedule.max_workers = 3;
ALTER SYSTEM SET schedule.max_parallel_workers = 3;
SELECT pg_reload_conf();
```

Once `pgpro_scheduler` is configured, enable it on your system, as follows:

```
SELECT schedule.enable();
```

If this function returns `true`, `pgpro_scheduler` is ready to use, and you can start scheduling jobs as explained in [Section F.40.3.1](#) and [Section F.40.3.2](#).

### Note

If you restart the server, `pgpro_scheduler` is not automatically restarted by default. To change this behavior, you can set the `schedule.auto_enabled` parameter to `on`.

## F.40.3. Usage

### F.40.3.1. Creating Scheduled Jobs

To create and schedule a job, run the `create_job()` function that takes scheduling options as a `jsonb` object:

```
schedule.create_job(options jsonb)
```

In the `jsonb` object, you must specify one or more SQL commands in the `commands` key, and set the job schedule with at least one of the following keys:

- `dates` — a single date or an array of dates, in the `timestamp with time zone` format
- `cron` — a string, in the `crontab` format. A traditional five-field `crontab` format is used. The first field stands for minute, the second — for hour, the third — for day of the month, the fourth — for month, and the fifth — for day of the week. A six-field `crontab` format can be used alongside the traditional five-field format. In this case the first field stands for second. When you use the six-field format and do not want to specify a second you have to put 0 in the first field.

Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started:

- `@every_second` — each second
- `@hourly` — at the beginning of each hour
- `@daily` — at the beginning of each day
- `@midnight` — at the beginning of each day
- `@weekly` — at the beginning of each week
- `@monthly` — at the beginning of each month
- `@yearly` — at the beginning of each year
- `@annually` — at the beginning of each year
- `rule` — a `jsonb` object that includes one or more of the following keys:
  - `seconds` — seconds; an array of integers in range [0, 59]

- `minutes` — minutes; an array of integers in range [0, 59]
- `hours` — hours; an array of integers in range [0, 23]
- `days` — days of the month; an array of integers in range [1, 31]
- `months` — months; an array of integers in range [1, 12]
- `wdays` — days of the week; an array of integers in range [0, 6], where 0 is Sunday.
- `onstart` — integer value 0 or 1. If `onstart` is set to 1, the job is executed only once when `pgpro_scheduler` is started.

You can combine `dates`, `cron`, and `rule` scheduling keys for advanced use cases.

As a result, `pgpro_scheduler` creates an active job with the specified schedule and returns the job ID.

### Tip

For simple job schedules, you can use the following shortcut syntax:

```
schedule.create_job(cron, commands)
schedule.create_job(dates, commands)
```

For details, see [schedule.create\\_job\(\)](#) function description.

If required, you can later modify one or more scheduling options with the `set_job_attribute()` or `set_job_attributes()` functions, respectively.

If all background workers are busy at the specified time, the job waits for the next available worker. By default, the job can wait forever. You can limit the maximum wait time by setting the `last_start_available` key, in the [time interval](#) format. If the timeout is reached, `pgpro_scheduler` cancels the job execution.

### Examples:

To run the job every day at 3pm, and, additionally, on December 31, 2017 at 7pm , and on April 4, 2020 at 1pm:

```
SELECT schedule.create_job('{"commands": "SELECT 15", "cron": "0 15 * * *", "dates":
[ "2017-12-31 19:00", "2020-04-04 13:00" ]}');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{"commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
*", "last_start_available": "30 seconds" }');
```

#### F.40.3.1.1. Specifying the Time Window for Job Execution

In addition to the general schedule, you can specify the timeframe during which the scheduled job can be executed. To ensure that `pgpro_scheduler` only executes the job within the specified time window, define the `start_date` and `end_date` keys, in the timestamp with time zone format. You can set one of these keys only to limit the start or the end time, respectively. If you define a time window for the job, `pgpro_scheduler` will only schedule this job within this time window. If the started job is incomplete when the specified time window ends, `pgpro_scheduler` completes the job and then excludes the job from further scheduling.

### Examples:

To start scheduling the job only after 11am on May 1, 2017:

```
SELECT schedule.create_job('{"commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00" }');
```

To schedule the job in the timeframe from 11am on May 1 to 3pm on June 4, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
  "start_date": "2017-05-01 11:00", "end_date": "2017-06-04 15:00" }');
```

#### F.40.3.1.2. Running SQL Commands in Separate Transactions

The `commands` key can have values of text and array types. If you specify several SQL commands as text separated by semicolons, the whole job is executed in a single transaction. If it is critical to perform each SQL command in a separate transaction, pass the SQL commands as an array. You can modify this behavior by setting the `use_same_transaction` key to `true`. In this case, SQL commands in the array are executed in a single transaction.

##### Examples:

To run the whole job in a single transaction:

```
SELECT schedule.create_job('{ "commands": "SELECT 1; SELECT 2; SELECT 3;", "cron": "23
  23 */2 * *" }');
```

To run commands in separate transactions:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
  "cron": "23 23 */2 * *" }');
```

To run the whole job in a single transaction when passing the commands as an array:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
  "cron": "23 23 */2 * *", "use_same_transaction": true }');
```

#### F.40.3.1.3. Calculating the Next Start Time of the Scheduled Job

For repeated jobs, the next start time can be computed by an SQL statement specified in the `next_time_statement` key. In this case, the first job starts on schedule, while all the successive job runs occur at the computed times.

After the job run completes, `pgpro_scheduler` executes the SQL statement in the `next_time_statement` key to calculate the next start time and returns the result, in the `timestamp with time zone` type. If the return value is of a different type or an error occurs, `pgpro_scheduler` marks the job as broken and cancels any further execution. This process is repeated for each successive job run.

#### Tip

When the job run completes, `pgpro_scheduler` sets the transaction state in the `schedule.transaction_state` variable, in the text format. You can use this variable in your `next_time_statement` to dynamically calculate the next start time depending on the transaction state. At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values for the main transaction. Other values may indicate an internal `pgpro_scheduler` error.

##### Examples:

To run the job first at 10:45, and then in a day after the job completes:

```
SELECT schedule.create_job('{ "commands": "SELECT random()", "cron": "45 10 * * *",
  "next_time_statement": "SELECT now() + '1 day'::interval" }');
```

#### F.40.3.1.4. Setting Additional Conditions for Job Execution

The `pgpro_scheduler` extension enables you to define additional conditions for task execution:

- Set time limits for job execution with the `max_run_time` key. If the execution time is exceeded, `pgpro_scheduler` cancels the job.

- Define the maximum time a scheduled job can wait for execution using the `last_start_available` key. If the timeout is reached, `pgpro_scheduler` cancels the job.
- Schedule a job to be executed with the rights of another user by specifying the `run_as` key. You must have superuser rights to use this key.
- Define an SQL command to execute if the main command fails using the `onrollback` key.

**Examples:**

To limit job execution to 5 seconds:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(10)", "cron": "15 */10 * * *", "max_run_time": "5 seconds" }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * * *", "last_start_available": "30 seconds" }');
```

To start the job with the rights of the `robot` user:

```
SELECT schedule.create_job('{ "commands": "SELECT session_user", "cron": "5 */5 * * *", "run_as": "robot" }');
```

To define a fallback SQL command in case the main command fails:

```
SELECT schedule.create_job('{ "commands": "SELECT '''zzz'''", "cron": "55 */12 * * *", "onrollback": "SELECT '''Cannot select zzz'''" }');
```

### F.40.3.2. Submitting One-Time Jobs

You can submit jobs for one-time execution using the `schedule.submit_job()` function. Such jobs use a separate pool of background workers defined by the `schedule.max_parallel_workers` variable, and can run in parallel with the scheduled jobs. By default, two one-time jobs can run concurrently. If you submit more jobs, they will wait in the queue for the next available background worker.

To execute a one-time job immediately, pass SQL commands in the `query` argument. For example:

```
schedule.submit_job(query := 'select 1');
```

Instead of passing SQL query parameters directly, you can define numbered placeholders in the `query` argument, such as `$1` and `$2`, and pass an array of parameters in the `params` argument, with each array element corresponding to a placeholder. For brevity, you can omit the `query` and `params` names:

```
schedule.submit_job(query := 'select $1, $2', params := '{"text 1", "text 2"}')
```

To start a one-time job at the specified time, use the `run_after` argument:

```
schedule.submit_job('select '''flowers'''', run_after := '2017-03-08 08:00:01');
```

Alternatively, you can delay the job start until the specified jobs are complete using the `depends_on` argument. For example, to run a job after completing the jobs with 23, 15, and 334 IDs, run:

```
schedule.submit_job('select '''well done'''', depends_on := '{23, 15, 334}')
```

If required, you can repeat the job execution by passing the `schedule.resubmit()` function as part of the `query` argument. For example:

```
schedule.submit_job('select 1, schedule.resubmit(run_after := '''5''')');
```

The `run_after` argument specifies the time interval before the job is restarted, in seconds. By default, the interval is 1 second.

The resubmitted job cannot be executed more than the number of times set in the `resubmit_limit` argument. If this limit is reached, the job receives the `done` status, with the corresponding error message.

If you want to cancel a resubmitted job, run:

```
schedule.cancel_job(job_id bigint);
```

To monitor one-time jobs, use the [job\\_status](#) and [all\\_job\\_status](#) `pgpro_scheduler` views.

For details on all the functions available for managing one-time jobs, see [Section F.40.4.6.3](#).

### F.40.3.3. Changing and Removing Scheduled Jobs

When you create a new job with the `create_job()` function, the job becomes active and waits for execution based on the specified schedule. Using the job ID returned by the `create_job()` function, you can change the scheduling settings or remove the job from the schedule. To change the specified schedule for the jobs, use `set_job_attribute()` or `set_job_attributes()` functions:

- To modify a single property of the job, run the `set_job_attribute()` function with the job ID, the property name to change, and the new value for this property.
- To modify more than one property of the job, run the `set_job_attributes()` function instead. In this case, you can specify all the job properties at once in a `jsonb` object. For details on all the keys available for job scheduling, see the `create_job()` function description.

To temporarily exclude the job from scheduling, run the `deactivate_job()` function:

```
schedule.deactivate_job(job_id integer)
```

You can re-activate the job later by running the `activate_job()` function:

```
schedule.activate_job(job_id integer)
```

To permanently remove the job from the schedule, run the `drop_job()` function:

```
schedule.drop_job(job_id integer)
```

### F.40.3.4. Monitoring Scheduled Jobs

You must have superuser rights to monitor job execution for the whole system. Otherwise, you can only monitor the jobs that you own. To monitor scheduled jobs, `pgpro_scheduler` provides multiple functions that return `cron_rec` or `cron_job` records:

- `get_job()` — retrieves information about the job.
- `get_owned_cron()` — retrieves the list of jobs owned by user.
- `get_cron()` — retrieves the list of jobs executed by user.
- `get_active_jobs()` — returns the list of jobs executed at the moment of the function call.
- `get_log()` — returns the list of all completed jobs.
- `get_user_log()` — returns list of the completed jobs executed by the specified user.
- `clean_log()` — deletes all records with information about completed jobs.

To learn more about each function, see [Section F.40.4.6](#).

### F.40.3.5. Auditing Job Scheduling

`pgpro_scheduler` enables you to audit job scheduling to rule out human error if you observe unexpected changes in scheduled job execution.

By default, `pgpro_scheduler` does not store information on schedule changes. To enable this feature, set the [schedule.enable\\_history](#) parameter to `true`. Once this parameter is enabled, `pgpro_scheduler` stores schedule modifications in the `schedule.cron__history` table, and logs all deleted jobs in the `schedule.cron__deleted` table. Logged history is never deleted from these tables, so a superuser can review schedule changes introduced by all users at any time.

For details on logged information, see [Section F.40.4.5](#).

### F.40.3.6. Scheduling Jobs on a Multi-Master Cluster

Using `pgpro_scheduler`, you can manage scheduled and one-time jobs on a cluster configured with [multimaster](#). `pgpro_scheduler` can only manage jobs on the node on which it is installed. Thus, you must install and enable `pgpro_scheduler` on all nodes on which you would like to schedule jobs. `pgpro_scheduler` instances will manage jobs on different nodes independently, but the executed jobs will be replicated to other nodes.

Even if you are planning to schedule jobs on a single node only, it is recommended to enable `pgpro_scheduler` on several nodes. In this case, if a node with scheduled jobs fails, another `pgpro_scheduler` instance picks up these jobs. If `pgpro_scheduler` is running on more than one node, the node with the smallest node ID is selected. The naming pattern of node IDs is defined by the [schedule.nodename](#) GUC variable.

## F.40.4. Reference

### F.40.4.1. GUC Variables

`schedule.enabled` (boolean)

Deprecated. Specifies whether `pgpro_scheduler` is enabled on your system.

Default: `false`.

For `pgpro_scheduler` 2.5 or higher, you can set the [schedule.auto\\_enabled](#) parameter to control whether `pgpro_scheduler` is enabled at the server start, or use `schedule.enable()/schedule.disable()` functions to enable/disable `pgpro_scheduler` on demand. To check if `pgpro_scheduler` is currently running, use the `schedule.is_enabled()` function.

`schedule.auto_enabled` (boolean)

Specifies whether to enable `pgpro_scheduler` at the server start.

Default: `false`.

`schedule.database` (text)

Specifies the databases for which `pgpro_scheduler` is enabled. Database names must be separated by commas.

Default: empty string.

`schedule.database_to_connect` (text)

The database to which `pgpro_scheduler` gets connected to receive Postgres Pro Enterprise cluster metadata. The specified database cannot be dropped while `pgpro_scheduler` is running. You can change this parameter only when restarting the server.

Default: `postgres`.

`schedule.schema` (text)

Deprecated. Specifies the name of a schema where the scheduler stores its tables and functions. If you need to change the default schema, use [ALTER EXTENSION](#).

Default: `schedule`.

`schedule.nodename` (text)

Specifies the name of the cluster node on which `pgpro_scheduler` is running. Do not change or use this variable if you run a single-server cluster configuration.

On a cluster configured with `multimaster`, the node name is derived from the node ID provided by `multimaster`. For example, if the node ID is 3, the `schedule.nodename` variable is set to `mtm-node-3`. However, if you explicitly set the `schedule.nodename` variable by editing the `postgresql.conf` file or running the `ALTER` command, `pgpro_scheduler` will ignore the node ID and use the provided value instead.

Default: `master`.

`schedule.max_workers` (integer)

Specifies the maximum number of simultaneously running scheduled jobs in one database.

Default: 2.

`schedule.max_parallel_workers` (integer)

Specifies the maximum number of parallel threads that can be used for executing one-time jobs.

Default: 2.

`schedule.transaction_state` (text)

An internal variable containing the state of the executed job. `pgpro_scheduler` uses this variable when calculating the next job start time. Possible values are:

- `success` — transaction has finished successfully.
- `failure` — transaction has failed to finish.
- `running` — transaction is in progress.
- `undefined` — transaction has not started yet.

At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values. Other values may indicate an internal `pgpro_scheduler` error.

`schedule.enable_history` (boolean)

Log all schedule changes, including the name of the user who initiated the change and the time when this change occurred. If a new job is added, or the schedule of an existing job is modified, this information is stored in the `schedule.cron__history` table. If a job is deleted, this information is stored in the `schedule.cron__deleted` table. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

Default: `false`

#### F.40.4.2. SQL Schema

To store its internal tables and functions, `pgpro_scheduler` uses the `schedule` SQL schema. Direct access to tables is not recommended and should not be attempted. To manage job scheduling, use the functions defined by the `pgpro_scheduler` extension.

#### F.40.4.3. SQL Types

`pgpro_scheduler` defines the following types that are used by some of the `pgpro_scheduler` functions.

##### F.40.4.3.1. `cron_rec`

This type contains information about the scheduled job.

```
CREATE TYPE schedule.cron_rec AS (  
    id integer,           -- job ID  
    node text,            -- name of the node  
                          -- on which to execute the job  
    name text,            -- job name
```

```

comments text,          -- comments about the job
rule jsonb,             -- scheduling rules
commands text[],        -- SQL commands to be executed
run_as text,            -- username of the job executor
owner text,             -- username of the job owner
start_date timestamptz, -- lower bound of the execution window;
                        -- NULL if unbound
end_date timestamptz,   -- upper bound of the execution window;
                        -- NULL if unbound
use_same_transaction boolean, -- true if an array of SQL
                        -- commands will be executed
                        -- in a single transaction
last_start_available interval, -- maximum wait time for
                        -- the scheduled job if all
                        -- allowed workers are busy
max_run_time interval,  -- maximum execution time
onrollback text,        -- SQL statement to execute
                        -- if the main transaction fails
max_instances int,      -- maximum number of simultaneously
                        -- running job instances
next_time_statement text, -- SQL statement to calculate
                        -- the next start time
active boolean,         -- true if job is scheduled
                        -- successfully
broken boolean          -- true if job has errors in
                        -- configuration that prevented
                        -- its further execution
);

```

#### F.40.4.3.2. cron\_job

This type contains information about a particular job execution.

```

CREATE TYPE schedule.cron_job AS(
  cron integer,          -- job id
  node text,             -- name of the node
                        -- on which to execute the job
  scheduled_at timestamptz, -- scheduled execution time
  name text,             -- job name
  comments text,         -- comments about the job
  commands text[],       -- SQL statement to be executed
  run_as text,           -- username of the job executor
  owner text,            -- username of the job owner
  use_same_transaction boolean, -- true if an array of SQL
                        -- commands will be executed
                        -- in a single transaction
  started timestamptz,    -- timestamp of the job execution start
  last_start_available timestamp, -- maximum wait time for
                        -- the scheduled job if all
                        -- allowed workers are busy
  finished timestamptz,   -- timestamp of the job
                        -- execution finish
  max_run_time interval,  -- maximum execution time
  onrollback text,        -- SQL statement to execute if the main
                        -- transaction fails
  next_time_statement text, -- SQL statement to calculate
                        -- the next start time
  max_instances int,      -- the number of simultaneously
                        -- running job instances
);

```

```
    status job_status_t,      -- status of the task:
                              -- working, done, or error
    message text              -- error message
);
```

#### F.40.4.3.3. `job_status_t`

Enumerated type. Can take the following values:

- `working` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.

#### F.40.4.3.4. `job_at_status_t`

Enumerated type. Can take the following values:

- `submitted` — the job is submitted into the queue, but the execution has not started yet.
- `processing` — the job is being executed.
- `done` — job execution is complete.

#### F.40.4.3.5. `timetable_job_type_t`

Enumerated type. Can take the following values:

- `periodical` — a scheduled job.
- `onetime` — a one-time job.

#### F.40.4.3.6. `timetable_job_status_t`

Enumerated type. Can take the following values:

- `inprogress` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.
- `submitted` — the job is submitted into the queue, but the execution has not started yet.

### F.40.4.4. Views

`pgpro_scheduler` provides several views for monitoring execution status of one-time jobs.

#### F.40.4.4.1. `job_status` View

Shows the status of one-time jobs belonging to the current user.

**Table F.27. `job_status` View**

| Column Name            | Column Type                           | Description                                          |
|------------------------|---------------------------------------|------------------------------------------------------|
| <code>id</code>        | <code>bigint</code>                   | Job ID.                                              |
| <code>node</code>      | <code>text</code>                     | Name of the node on which the job is being executed. |
| <code>name</code>      | <code>text</code>                     | Name of the job.                                     |
| <code>comments</code>  | <code>text</code>                     | Comments about the job.                              |
| <code>run_after</code> | <code>timestamp with time zone</code> | Timestamp after which the job execution must start.  |
| <code>query</code>     | <code>text</code>                     | SQL commands executed by the job.                    |

| Column Name       | Column Type              | Description                                                                                                                                          |
|-------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| params            | text[]                   | An array of parameters for the SQL query.                                                                                                            |
| depends_on        | bigint[]                 | An array of job IDs on which the job execution depends.                                                                                              |
| run_as            | text                     | User or role whose rights are used to execute the job.                                                                                               |
| attempt           | bigint                   | The number of execution attempts.                                                                                                                    |
| resubmit_limit    | bigint                   | The maximum number of allowed job resubmissions.                                                                                                     |
| max_wait_interval | interval                 | The maximum time interval to postpone the job execution if all background workers are busy at the scheduled moment.                                  |
| max_duration      | interval                 | Time interval during which the job can be executed.                                                                                                  |
| submit_time       | timestamp with time zone | Time when the job was submitted to the execution queue.                                                                                              |
| canceled          | boolean                  | Specifies whether the job was canceled by user.                                                                                                      |
| start_time        | timestamp with time zone | Job execution start time.                                                                                                                            |
| is_success        | boolean                  | <ul style="list-style-type: none"> <li>true — job execution completed successfully.</li> <li>false — job execution completed with errors.</li> </ul> |
| error             | text                     | Error message.                                                                                                                                       |
| done_time         | timestamp with time zone | Time when the job execution completed.                                                                                                               |
| status            | job_at_status_t          | Job status. See the <a href="#">Section F.40.4.3.4</a> for details.                                                                                  |

#### F.40.4.4.2. all\_job\_status View

Shows the status of all one-time jobs. You must have superuser rights to access this view.

**Table F.28. all\_job\_status View**

| Column Name | Column Type              | Description                                          |
|-------------|--------------------------|------------------------------------------------------|
| id          | bigint                   | Job ID.                                              |
| node        | text                     | Name of the node on which the job is being executed. |
| name        | text                     | Name of the job.                                     |
| comments    | text                     | Comments about the job.                              |
| run_after   | timestamp with time zone | Timestamp after which the job execution must start.  |
| query       | text                     | SQL commands executed by the job.                    |
| params      | text[]                   | An array of parameters for the SQL query.            |

| Column Name       | Column Type              | Description                                                                                                                                                                        |
|-------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| depends_on        | bigint[]                 | An array of job IDs on which the job execution depends.                                                                                                                            |
| run_as            | text                     | User or role whose rights are used to execute the job.                                                                                                                             |
| owner             | text                     | The user who created the job.                                                                                                                                                      |
| attempt           | bigint                   | The number of execution attempts.                                                                                                                                                  |
| resubmit_limit    | bigint                   | The maximum number of allowed job resubmissions.                                                                                                                                   |
| max_wait_interval | interval                 | The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment.                                                            |
| max_duration      | interval                 | Time interval during which the job can be executed.                                                                                                                                |
| submit_time       | timestamp with time zone | Time when the job was submitted to the execution queue.                                                                                                                            |
| canceled          | boolean                  | Specifies whether the job was canceled by user.                                                                                                                                    |
| start_time        | timestamp with time zone | Job execution start time.                                                                                                                                                          |
| is_success        | boolean                  | <ul style="list-style-type: none"> <li>• <code>true</code> — job execution completed successfully.</li> <li>• <code>false</code> — job execution completed with errors.</li> </ul> |
| error             | text                     | Error message.                                                                                                                                                                     |
| done_time         | timestamp with time zone | Time when the job execution completed.                                                                                                                                             |
| status            | job_at_status_t          | Job status. See the <a href="#">Section F.40.4.3.4</a> for details.                                                                                                                |

### F.40.4.5. Audit Tables

The following tables store all schedule changes if the `schedule.enable_history` parameter is set to `true`. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

#### F.40.4.5.1. `schedule.cron_history` Table

Registers job scheduling changes. Whenever a new job is scheduled, or the schedule for an existing job is changed, a new row is inserted into this table to record the following information:

- All details about the scheduled job, as defined by the `cron_rec` data type. For details on the `cron_rec` type, see [Section F.40.4.3](#).
- `submitter` — name of the user who updated the schedule.
- `version_id` — a unique ID for each registered change in the schedule.
- `submit_time` — time when the schedule was updated.

#### F.40.4.5.2. `schedule.cron_deleted` Table

Registers all jobs that were removed from the schedule:

- `cron` — ID of the deleted job.

- `submitter` — name of the user who deleted the job.
- `submit_time` — time when the job was deleted.

#### F.40.4.6. Functions

`pgpro_scheduler` provides two separate sets of functions for managing scheduled and one-time jobs, as well as several common functions that can toggle `pgpro_scheduler` on and off for your database and show the current status of the extension:

- [Section F.40.4.6.1](#)
- [Section F.40.4.6.2](#)
- [Section F.40.4.6.3](#)
- [Section F.40.4.6.4](#)

### Important

With each job, you can only use the function specifically tailored for this job type.

#### F.40.4.6.1. Common Functions

These functions facilitate `pgpro_scheduler` management.

`schedule.enable()`

Enables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if the command has failed.

`schedule.is_enabled()`

Checks whether `pgpro_scheduler` is enabled.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if `pgpro_scheduler` is not currently running.

`schedule.disable()`

Disables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is disabled.
- `false` if the command has failed.

`schedule.start()`

Launches `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` started successfully.
- `false` — if the command has failed, or `pgpro_scheduler` is already started.

`schedule.stop()`

Stops `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` is stopped.
- `false` — if the command has failed, or `pgpro_scheduler` is not running.

`schedule.status()`

Returns the status of `pgpro_scheduler` background workers:

- `pid` — process ID of the background worker. If the process ID is `NULL`, the background worker is not running.
- `database` — name of the database to which the background worker is connected.
- `type` — type of the background worker:
  - `supervisor` — distributes the scheduled jobs between the databases.
  - `database manager` distributes the scheduled jobs within the database.
  - `cron job executor` executes a scheduled job.
  - `at job executor` executes a one-time job.

`schedule.version()`

Returns `pgpro_scheduler` version.

#### F.40.4.6.2. Functions for Managing Scheduled Jobs

`schedule.create_job(options jsonb)`

Creates an active job and returns the job ID.

##### Alternative Syntax:

```
schedule.create_job(cron text, commands text [, node text])
schedule.create_job(cron text, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone, commands text [, node text])
schedule.create_job(dates timestamp with time zone, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone[], commands text [, node text])
schedule.create_job(dates timestamp with time zone[], commands text[] [, node text])
```

Arguments:

- `options` — a `jsonb` object defining all the job properties. You do not need to define other parameters if the `data` is set. All the available `jsonb` keys are listed in [Table F.29](#).

Type: `jsonb`

- `cron` — a crontab-like string defining the job schedule.

Type: `text`

- `dates` — the exact date or an array of dates for job execution.

Type: `timestamp with time zone, timestamp with time zone[]`

- `commands` — SQL statement to execute. You can pass one or more SQL commands separated by semicolons, or an array of SQL commands. When passed as an array, SQL commands are executed in separate transactions.

Type: `text, text[]`

- `node` — the name of the node on which the scheduled jobs run. Optional. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.

Type: `text`

Return values:

- ID of the created job.

**Table F.29. jsonb Keys for Job Scheduling**

| Key   | Type                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cron  | text                                                 | <p>A crontab-like string defining the job schedule. A traditional five-field or nonstandard six-field (seconds in the first field) crontab format may be used. You can combine <code>cron</code> with <code>rule</code> and <code>dates</code> keys, but at least one of them is mandatory. Alternatively, the following keywords can be used instead of a crontab string to specify when the job will be started:</p> <ul style="list-style-type: none"> <li>• <code>@every_second</code> — each second</li> <li>• <code>@hourly</code> — at the beginning of each hour</li> <li>• <code>@daily</code> — at the beginning of each day</li> <li>• <code>@midnight</code> — at the beginning of each day</li> <li>• <code>@weekly</code> — at the beginning of each week</li> <li>• <code>@monthly</code> — at the beginning of each month</li> <li>• <code>@yearly</code> — at the beginning of each year</li> <li>• <code>@annually</code> — at the beginning of each year</li> </ul> |
| dates | timestamp with time zone, timestamp with time zone[] | The exact date or an array of dates when the scheduled job will be executed. You can combine <code>dates</code> with <code>rule</code> and <code>cron</code> keys, but at least one of them is mandatory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| rule  | jsonb                                                | <p>A jsonb object defining the job schedule. Mandatory, if both <code>cron</code> and <code>dates</code> keys are undefined. The <code>rule</code> object includes one or more of the following keys:</p> <ul style="list-style-type: none"> <li>• <code>seconds</code> — seconds; an array of integers in range [0, 59]</li> <li>• <code>minutes</code> — minutes; an array of integers in range [0, 59]</li> <li>• <code>hours</code> — hours; an array of integers in range [0, 23]</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Key                               | Type                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                   |                                       | <ul style="list-style-type: none"> <li><code>days</code> — days of the month; an array of integers in range [1, 31]</li> <li><code>months</code> — months; an array of integers in range [1, 12]</li> <li><code>wdays</code> — days of the week; an array of integers in range [0, 6], where 0 is Sunday.</li> <li><code>onstart</code> — integer value 0 or 1. If <code>onstart</code> is set to 1, the job is executed only once when <code>pgpro_scheduler</code> is started.</li> </ul> |
| <code>commands</code>             | <code>text, text[]</code>             | SQL statements to execute. You can pass one or more SQL statements separated by semicolons, or an array of SQL statements. When passed as an array, SQL statements are executed in separate transactions by default. You can change this behavior by setting the <code>use_same_transaction</code> key.                                                                                                                                                                                     |
| <code>name</code>                 | <code>text</code>                     | Optional. Job name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>node</code>                 | <code>text</code>                     | Optional. The name of the node on which the scheduled jobs run. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.                                                                                                                                                                                                                                                                                                                                 |
| <code>comments</code>             | <code>text</code>                     | Optional. Comments about the scheduled job.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>run_as</code>               | <code>text</code>                     | Optional. The user whose rights are used to execute the job.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>start_date</code>           | <code>timestamp with time zone</code> | Optional. The start of the time-frame when the scheduled job can be executed. This key can be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                           |
| <code>end_date</code>             | <code>timestamp with time zone</code> | Optional. The end of the time-frame when the scheduled job can be executed. This key can be <code>NULL</code> .                                                                                                                                                                                                                                                                                                                                                                             |
| <code>use_same_transaction</code> | <code>boolean</code>                  | Optional. If set to <code>true</code> , forces an array of SQL statements to be executed in a single transaction. Default: <code>false</code>                                                                                                                                                                                                                                                                                                                                               |
| <code>last_start_available</code> | <code>interval</code>                 | Optional. The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to <code>'00:02:34'</code> , the job will                                                                                                                                                                                                                                                                                 |

| Key                              | Type                  | Description                                                                                                                                                                             |
|----------------------------------|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                  |                       | wait for 2 minutes 34 seconds. If this key is <code>NULL</code> or not set, the job can wait forever. Default: <code>NULL</code> .                                                      |
| <code>max_instances</code>       | <code>integer</code>  | Optional. The maximum number of job instances that can be executed simultaneously. Default: 1.                                                                                          |
| <code>max_run_time</code>        | <code>interval</code> | Optional. The maximum time interval during which the scheduled job can be executed. If this key is <code>NULL</code> or not set, there are no time limits. Default: <code>NULL</code> . |
| <code>onrollback</code>          | <code>text</code>     | Optional. SQL statement to be executed if the main transaction fails.                                                                                                                   |
| <code>next_time_statement</code> | <code>text</code>     | Optional. SQL statement to calculate the start time for the next job execution. For details, see <a href="#">Section F.40.3.1.3</a> .                                                   |

```
schedule.set_job_attributes(job_id integer, data jsonb)
```

Updates properties of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `data` — a `jsonb` object with properties to be edited. For the list of keys and their structure, see [Table F.29](#).

Return values:

- `true` — job properties were updated successfully.
- `false` — job properties were not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

```
schedule.set_job_attribute(job_id integer, name text, value text || anyarray)
```

Updates a property of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `name` — property name.
- `value` — property value.

See [Table F.29](#) for the list of job properties you can update. Some values are of array types. They should be passed as an array. If a value of a wrong type is passed, an exception is raised.

Return values:

- `true` — job property was updated successfully.
- `false` — job property was not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

```
schedule.deactivate_job(job_id integer)
```

Deactivates the job and suspends its further scheduling and execution.

**Arguments:**

- *job\_id* — identifier of the existing job.

**Return values:**

- `true` — the job is deactivated successfully.
- `false` — job deactivation failed.

```
schedule.activate_job(job_id integer)
```

Activates a job and starts its scheduling and execution.

**Arguments:**

- *job\_id* — identifier of the existing job.

**Return values:**

- `true` — the job was activated successfully.
- `false` — job activation failed.

```
schedule.drop_job(job_id integer)
```

Deletes a job.

**Arguments:**

- *job\_id* — identifier of the existing job.

**Return values:**

- `true` — the job was deleted successfully.
- `false` — job was not deleted.

```
schedule.get_job(job_id integer)
```

Returns information about the specified job.

**Arguments:**

- *job\_id* — identifier of the existing job.

**Return values:**

- An object of type `cron_rec`.

For details on the `cron_rec` type, see [Section F.40.4.3](#).

```
schedule.get_owned_cron(username text)
```

Retrieves the list of jobs owned by the specified user.

**Arguments:**

- *username* — username, optional.

**Return values:**

- A set of records of type `cron_rec`. These records contain information about all jobs owned by the specified user. If the *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs owned by another user.

For details on the `cron_rec` type, see [Section F.40.4.3](#).

```
schedule.get_cron(username text)
```

Retrieves the list of jobs executed by the specified user.

**Arguments:**

- *username* — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs executed by the specified user. If *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

For details on the `cron_rec` type, see [Section F.40.4.3](#).

```
schedule.get_active_jobs(username text)
```

Returns the list of jobs currently being executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.40.4.3](#).

```
schedule.get_active_jobs()
```

Returns the list of jobs being currently executed. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.40.4.3](#).

```
schedule.get_log()
```

Returns the list of all completed jobs. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.40.4.3](#).

```
schedule.get_user_log(username text)
```

Returns the list of completed jobs executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve the list of jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.40.4.3](#).

```
schedule.clean_log()
```

Deletes all records with information about the completed jobs. You must have superuser rights to call this function.

Return values:

- The number of records deleted.

```
schedule.nodename()
```

Returns the current node name.

#### F.40.4.6.3. Functions for Managing One-Time Jobs

```
schedule.submit_job(query text [options...])
```

Submits a job for immediate or delayed one-time execution. By default, the job is scheduled for immediate execution and can run in parallel with other scheduled jobs. To submit a job with a delayed start, you can set the execution start time using the *run\_after* argument, or pass an array of job IDs in the *depends\_on* argument to schedule job execution right after these jobs are complete.

Arguments:

- *query* — SQL commands to execute.

Type: text

- *params* — an array of parameters for the SQL query that can substitute numbered placeholders in the *query* argument, such as \$1, \$2, etc. Default: NULL

Type: text[]

- *run\_after* — a timestamp after which the job execution starts. If this argument is set to NULL, the job is scheduled for immediate execution. You can also use the *depends\_on* argument to delay the job start. Default: NULL

Type: timestamp with time zone

- *node* — the name of the node on which to execute the job. Default: NULL

Type: text

- *max\_duration* — the maximum time interval during which the job can be executed. If this time is exceeded, the job is forced to stop. If this argument is NULL or not set, there are no time limits. Default: NULL

Type: interval

- *max\_wait\_interval* — the maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is NULL or not set, the job can wait forever. Default: NULL

Type: interval

- *run\_as* — user or role whose rights are used to execute the job. If *run\_as* is set to NULL, the job is executed with the rights of the current user. You must have superuser rights to set this argument. Default: NULL

Type: text

- *depends\_on* — an array of job IDs. The created job starts immediately after the specified jobs complete the execution. This argument is an alternative to *run\_after*. Default: NULL

Type: bigint[]

- *name* — name of the job. Default: NULL

Type: text

- *comments* — comments about the job.

Type: text

- *resubmit\_limit* — maximum number of times the job can be resubmitted for execution. See the `schedule.resubmit()` function for details. Default: 100

Type: bigint

Return values:

- ID of the created job.

Type: bigint

`schedule.get_self_id()`

Returns the ID of the job, in the context of which it was called. The returned ID is of the `bigint` type. This function must be called inside the *query* of the `schedule.submit_job()` function. Otherwise, an exception is raised.

Return values:

- Job ID.

`schedule.cancel_job(job_id bigint)`

Cancels all subsequent runs of the specified job. If the job is currently being executed, it will not be interrupted, but cannot be resubmitted. You must have superuser rights or be the owner of the job to call this function.

Arguments:

- *job\_id* — identifier of the job to cancel.

Return values:

- `true` if the operation completed successfully.
- `false` if the operation failed.

`schedule.resubmit(run_after interval default NULL)`

Sets the start time for the next execution of the job, without interrupting the current job run. This function must be called inside the *query* argument of the `schedule.submit_job()` function. Otherwise, an exception is raised. If this function is called several times within a single job execution, only the last function call is taken into account.

Arguments:

- *run\_after* — time interval after which the job will be resubmitted for execution. Default: 1 second

Type: interval

Return values:

- The number of seconds after which the job will be resubmitted for execution.

#### F.40.4.6.4. Functions for Managing Scheduled and One-Time Jobs

`schedule.timetable(start_time timestamp with time zone, end_time timestamp with time zone)`

Returns a table, which describes all the jobs, both repeated and one-time, that are scheduled to execute within the specified time interval.

**Table F.30. `schedule.timetable` Columns**

| Column Name | Column Type          | Description                                                   |
|-------------|----------------------|---------------------------------------------------------------|
| id          | bigint               | Job ID, which is unique for the jobs of this type.            |
| type        | timetable_job_type_t | Job type. See <a href="#">Section F.40.4.3.5</a> for details. |
| node        | text                 | Name of the node on which the job is being executed.          |

| Column Name  | Column Type              | Description                                                     |
|--------------|--------------------------|-----------------------------------------------------------------|
| name         | text                     | Name of the job.                                                |
| comments     | text                     | Comments about the job.                                         |
| commands     | text[]                   | An array of SQL commands executed by the job.                   |
| scheduled_at | timestamp with time zone | Scheduled job execution time.                                   |
| start_time   | timestamp with time zone | Job execution start time.                                       |
| done_time    | timestamp with time zone | Time when the job execution completed.                          |
| status       | timetable_job_status_t   | Job status. See <a href="#">Section F.40.4.3.6</a> for details. |
| error        | text                     | Error message.                                                  |

## F.40.5. Authors

Postgres Professional, Moscow, Russia

## F.41. pg\_query\_state

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

### F.41.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

### F.41.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

### F.41.3. Installation

To install `pg_query_state` run in `psql`:

```
CREATE EXTENSION pg_query_state;
```

Then modify `shared_preload_libraries` parameter in `postgres.conf` as following:

```
shared_preload_libraries = 'pg_query_state'
```

It will require to restart the Postgres Pro instance.

### F.41.4. Function `pg_query_state`

```
pg_query_state(integer pid,
               verbose boolean DEFAULT FALSE,
               costs   boolean DEFAULT FALSE,
```

```
        timing    boolean DEFAULT FALSE,
        buffers   boolean DEFAULT FALSE,
        triggers  boolean DEFAULT FALSE,
        format    text      DEFAULT 'text')
returns TABLE (pid integer,
               frame_number integer,
               query_text text,
               plan text,
               leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain `WARNING message timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain `WARNING message buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints `INFO` message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints `ERROR` message `permission denied`.

## F.41.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. `WARNING`: if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

## F.41.6. Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with pid = 49265 performs a simple query:

```
postgres=# select pg_backend_pid();
pg_backend_pid
-----
      49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |      Workers Planned: 2
              |
              |      Workers Launched: 2
              |
              |      -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=12, loop
number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 5673232
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
              |
              |      -> Seq Scan on bar (actual rows=500000 loops=11)
              |      (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |      -> Nested Loop (Current loop: actual rows=10, loop number=1)
              |
              |      Join Filter: (foo.c1 = bar.c1)
              |
              |      Rows Removed by Join Filter: 4896779
              |
              |      -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)
              |
              |      -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
leader_pid   | 49265
```

```
-[ RECORD
 3 ]+-----
pid          | 49323
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              +
              | -> Nested Loop (Current loop: actual rows=11, loop number=1)
              +
              |         Join Filter: (foo.c1 = bar.c1)
              +
              |         Rows Removed by Join Filter: 5268783
              +
              |         -> Parallel Seq Scan on foo (Current loop: actual rows=11, loop
number=1)
              +
              |         -> Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
actual rows=268794, loop number=11)
leader_pid   | 49265
```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their `leader_pid` column's values clarify that these workers belong to the main backend. `Seq Scan` node has statistics on passed loops (average number of rows delivered to `Nested Loop` and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```
postgres=# select * from pg_query_state(49265);
-[ RECORD
 1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
 2 ]+-----
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | Result (Current loop: actual rows=0, loop number=1)
              +
              |   InitPlan 1 (returns $0)
              +
              |   -> Aggregate (Current loop: actual rows=0, loop number=1)
              +
              |   -> Nested Loop (Current loop: actual rows=51, loop number=1)
              +
              |         Join Filter: (foo.c1 = bar.c1)
              +
              |         Rows Removed by Join Filter: 51636304
              +
              |         -> Seq Scan on bar (Current loop: actual rows=52, loop
number=1)
```

```

|                                     -> Materialize (actual rows=1000000 loops=51) (Current
loop: actual rows=636355, loop number=52)+
|                                     -> Seq Scan on foo (Current loop: actual
rows=1000000, loop number=1)
leader_pid | (null)

```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```

postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----+
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {                                     +

## F.42. pgrowlocks

The `pgrowlocks` module provides a function to show row locking information for a specified table.

By default use is restricted to superusers, members of the `pg_stat_scan_tables` role, and users with `SELECT` permissions on the table.

## F.42.1. Overview

`pgrowlocks(text)` returns `setof record`

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.31](#).

**Table F.31. `pgrowlocks` Output Columns**

| Name                    | Type                   | Description                                                                                                                                                 |
|-------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>locked_row</code> | <code>tid</code>       | Tuple ID (TID) of locked row                                                                                                                                |
| <code>locker</code>     | <code>xid</code>       | Transaction ID of locker, or multi-<br>xact ID if multitransaction                                                                                          |
| <code>multi</code>      | <code>boolean</code>   | True if locker is a multitransac-<br>tion                                                                                                                   |
| <code>xids</code>       | <code>xid[]</code>     | Transaction IDs of lockers (more<br>than one if multitransaction)                                                                                           |
| <code>modes</code>      | <code>text[]</code>    | Lock mode of lockers (more than<br>one if multitransaction), an array<br>of Key Share, Share, For No Key<br>Update, No Key Update, For Up-<br>date, Update. |
| <code>pids</code>       | <code>integer[]</code> | Process IDs of locking backends<br>(more than one if multitransac-<br>tion)                                                                                 |

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

## F.42.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,2)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,3)      | 607   | f     | {607} | {"For Update"} | {3107}
(0,4)      | 607   | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

Tatsuo Ishii

## F.43. `pg_stat_statements`

The `pg_stat_statements` module provides a means for tracking execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to [shared\\_preload\\_libraries](#) in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When `pg_stat_statements` is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, `pg_stat_statements`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

### F.43.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.32](#).

**Table F.32. `pg_stat_statements` Columns**

| Name                         | Type                          | References                    | Description                                                                   |
|------------------------------|-------------------------------|-------------------------------|-------------------------------------------------------------------------------|
| <code>userid</code>          | <code>oid</code>              | <code>pg_authid</code> .oid   | OID of user who executed the statement                                        |
| <code>dbid</code>            | <code>oid</code>              | <code>pg_database</code> .oid | OID of database in which the statement was executed                           |
| <code>queryid</code>         | <code>bigint</code>           |                               | Internal hash code, computed from the statement's parse tree                  |
| <code>query</code>           | <code>text</code>             |                               | Text of a representative statement                                            |
| <code>calls</code>           | <code>bigint</code>           |                               | Number of times executed                                                      |
| <code>total_time</code>      | <code>double precision</code> |                               | Total time spent in the statement, in milliseconds                            |
| <code>min_time</code>        | <code>double precision</code> |                               | Minimum time spent in the statement, in milliseconds                          |
| <code>max_time</code>        | <code>double precision</code> |                               | Maximum time spent in the statement, in milliseconds                          |
| <code>mean_time</code>       | <code>double precision</code> |                               | Mean time spent in the statement, in milliseconds                             |
| <code>stddev_time</code>     | <code>double precision</code> |                               | Population standard deviation of time spent in the statement, in milliseconds |
| <code>rows</code>            | <code>bigint</code>           |                               | Total number of rows retrieved or affected by the statement                   |
| <code>shared_blks_hit</code> | <code>bigint</code>           |                               | Total number of shared block cache hits by the statement                      |

| Name                | Type             | References | Description                                                                                                                    |
|---------------------|------------------|------------|--------------------------------------------------------------------------------------------------------------------------------|
| shared_blks_read    | bigint           |            | Total number of shared blocks read by the statement                                                                            |
| shared_blks_dirtied | bigint           |            | Total number of shared blocks dirtied by the statement                                                                         |
| shared_blks_written | bigint           |            | Total number of shared blocks written by the statement                                                                         |
| local_blks_hit      | bigint           |            | Total number of local block cache hits by the statement                                                                        |
| local_blks_read     | bigint           |            | Total number of local blocks read by the statement                                                                             |
| local_blks_dirtied  | bigint           |            | Total number of local blocks dirtied by the statement                                                                          |
| local_blks_written  | bigint           |            | Total number of local blocks written by the statement                                                                          |
| temp_blks_read      | bigint           |            | Total number of temp blocks read by the statement                                                                              |
| temp_blks_written   | bigint           |            | Total number of temp blocks written by the statement                                                                           |
| blk_read_time       | double precision |            | Total time the statement spent reading blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |
| blk_write_time      | double precision |            | Total time the statement spent writing blocks, in milliseconds (if <a href="#">track_io_timing</a> is enabled, otherwise zero) |

For security reasons, only superusers and members of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

As a rule of thumb, `queryid` values can be assumed to be stable and comparable only so long as the underlying server version and catalog metadata details stay exactly the same. Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

## F.43.2. Functions

`pg_stat_statements_reset()` returns void

`pg_stat_statements_reset` discards all statistics gathered so far by `pg_stat_statements`. By default, this function can only be executed by superusers.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

### F.43.3. Configuration Parameters

`pg_stat_statements.max` (integer)

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track` (enum)

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility` (boolean)

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.save` (boolean)

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

pg_stat_statements.max = 10000
pg_stat_statements.track = all
```

### F.43.4. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

$ pgbench -i bench
$ pgbench -c10 -t300 bench

bench=# \x
bench=# SELECT query, calls, total_time, rows, 100.0 * shared_blks_hit /
           nullif(shared_blks_hit + shared_blks_read, 0) AS hit_percent
           FROM pg_stat_statements ORDER BY total_time DESC LIMIT 5;

calls      | 3000
total_time | 271.7419999999997
rows       | 3000
hit_percent | 93.7968855088209426
-[ RECORD 5 ]-----
query      | alter table pgbench_accounts add primary key (aid)
calls      | 1
total_time | 81.42
rows       | 0
hit_percent | 34.4947735191637631

```

### F.43.5. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

## F.44. pgstattuple

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

### F.44.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```

test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len      | 458752
tuple_count    | 1470
tuple_len      | 438896
tuple_percent  | 95.67
dead_tuple_count | 11
dead_tuple_len | 3157
dead_tuple_percent | 0.69
free_space     | 8932
free_percent   | 1.95

```

The output columns are described in [Table F.33](#).

**Table F.33. `pgstattuple` Output Columns**

| Column                   | Type                | Description                       |
|--------------------------|---------------------|-----------------------------------|
| <code>table_len</code>   | <code>bigint</code> | Physical relation length in bytes |
| <code>tuple_count</code> | <code>bigint</code> | Number of live tuples             |

| Column             | Type   | Description                          |
|--------------------|--------|--------------------------------------|
| tuple_len          | bigint | Total length of live tuples in bytes |
| tuple_percent      | float8 | Percentage of live tuples            |
| dead_tuple_count   | bigint | Number of dead tuples                |
| dead_tuple_len     | bigint | Total length of dead tuples in bytes |
| dead_tuple_percent | float8 | Percentage of dead tuples            |
| free_space         | bigint | Total free space in bytes            |
| free_percent       | float8 | Percentage of free space             |

### Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version           | 2
tree_level        | 0
index_size        | 16384
root_block_no     | 1
internal_pages    | 0
leaf_pages        | 1
empty_pages       | 0
deleted_pages     | 0
avg_leaf_density  | 54.27
leaf_fragmentation | 0
```

The output columns are:

| Column         | Type    | Description                              |
|----------------|---------|------------------------------------------|
| version        | integer | B-tree version number                    |
| tree_level     | integer | Tree level of the root page              |
| index_size     | bigint  | Total index size in bytes                |
| root_block_no  | bigint  | Location of root page (zero if none)     |
| internal_pages | bigint  | Number of “internal” (upper-level) pages |

| Column             | Type   | Description                   |
|--------------------|--------|-------------------------------|
| leaf_pages         | bigint | Number of leaf pages          |
| empty_pages        | bigint | Number of empty pages         |
| deleted_pages      | bigint | Number of deleted pages       |
| avg_leaf_density   | float8 | Average density of leaf pages |
| leaf_fragmentation | float8 | Leaf page fragmentation       |

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
version          | 1
pending_pages    | 0
pending_tuples   | 0
```

The output columns are:

| Column         | Type    | Description                          |
|----------------|---------|--------------------------------------|
| version        | integer | GIN version number                   |
| pending_pages  | integer | Number of pages in the pending list  |
| pending_tuples | bigint  | Number of tuples in the pending list |

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-
version          | 4
bucket_pages     | 33081
overflow_pages   | 0
bitmap_pages     | 1
unused_pages     | 32455
live_items       | 10204006
dead_items       | 0
free_percent     | 61.8005949100872
```

The output columns are:

| Column  | Type    | Description         |
|---------|---------|---------------------|
| version | integer | HASH version number |

| Column         | Type   | Description              |
|----------------|--------|--------------------------|
| bucket_pages   | bigint | Number of bucket pages   |
| overflow_pages | bigint | Number of overflow pages |
| bitmap_pages   | bigint | Number of bitmap pages   |
| unused_pages   | bigint | Number of unused pages   |
| live_items     | bigint | Number of live tuples    |
| dead_tuples    | bigint | Number of dead tuples    |
| free_percent   | float  | Percentage of free space |

`pg_relpages(regclass)` returns `bigint`

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns `bigint`

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as `TEXT`. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns `record`

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
scanned_percent    | 2
approx_tuple_count | 2740
approx_tuple_len   | 561210
approx_tuple_percent | 97.87
dead_tuple_count   | 0
dead_tuple_len     | 0
dead_tuple_percent | 0
approx_free_space  | 11996
approx_free_percent | 2.09
```

The output columns are described in [Table F.34](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.relpages`).

**Table F.34. `pgstattuple_approx` Output Columns**

| Column    | Type   | Description                               |
|-----------|--------|-------------------------------------------|
| table_len | bigint | Physical relation length in bytes (exact) |

| Column               | Type   | Description                                      |
|----------------------|--------|--------------------------------------------------|
| scanned_percent      | float8 | Percentage of table scanned                      |
| approx_tuple_count   | bigint | Number of live tuples (estimated)                |
| approx_tuple_len     | bigint | Total length of live tuples in bytes (estimated) |
| approx_tuple_percent | float8 | Percentage of live tuples                        |
| dead_tuple_count     | bigint | Number of dead tuples (exact)                    |
| dead_tuple_len       | bigint | Total length of dead tuples in bytes (exact)     |
| dead_tuple_percent   | float8 | Percentage of dead tuples                        |
| approx_free_space    | bigint | Total free space in bytes (estimated)            |
| approx_free_percent  | float8 | Percentage of free space                         |

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

## F.45. pg\_transfer

The `pg_transfer` extension enables quick transfer of tables between Postgres Pro Enterprise instances.

It may sometimes be required to load large volumes of data into a database, for example, when consolidating data from regional servers into a central one. If your data needs to be uploaded to a server under heavy load, you can use a temporary database on another server to accumulate the data and then transfer it all at once when the main server load is minimal.

If you use `pg_dump` and `pg_restore` applications to transfer data, the load on the receiving server is usually higher than that on the sending server. Since the data is loaded using `INSERT` or `COPY` commands, it creates a significant impact on the disk subsystem. Besides, you will have to re-build indexes in the target database once all the data is loaded, which will also contribute to the server load.

To achieve a much higher load speed for read-only data, you can use the `pg_transfer` extension while doing dump/restore, which allows to copy data files directly, without using `COPY/INSERT` commands. `pg_transfer` also provides auxiliary functions for `pg_dump` and `pg_restore` to transfer tables together with pre-built indexes and collected statistics, so you can avoid extra load on the target server incurred by statistics re-collection.

### Note

Postgres Pro Enterprise configuration and the architectures of source and target servers must provide binary-compatible file formats. When restoring data, `pg_transfer` checks that source and target servers have the same alignment, page and segment sizes, etc.

## F.45.1. Installation

`pg_transfer` is included into Postgres Pro Enterprise. To enable `pg_transfer`, create its extension in your database using the following SQL command:

```
CREATE EXTENSION pg_transfer;
```

You must create `pg_transfer` extension in both source and target databases.

## F.45.2. Usage

To transfer data using the `pg_transfer` module, do the following:

### 1. Prepare source and target systems for data transfer

Before the actual data transfer, you first need to transfer data schema to the target server:

1. In the source database, mark the table to be transferred as read-only:

```
ALTER TABLE table_name SET CONSTANT;
```

2. Run the `VACUUM (ANALYZE)` command to remove dead tuples and refresh statistics:

```
VACUUM (ANALYZE) table_name;
```

3. Take a logical dump of the data schema on the source server and restore it on the target server:

```
pg_dump -Fc -t table_name --schema-only -f transfer_dir/archive.out old_database
pg_restore -d new_database --schema-only transfer_dir/archive.out
```

### 2. Prepare TOAST identifiers for the transfer

This step is only required if the tables to be transferred have toasted values.

1. Determine TOAST identifiers (`reltoastid`) in the new database:

```
psql new_database -c "SELECT reltoastrelid FROM pg_class WHERE
    relname='table_name';"
```

2. Using the received `reltoastid` identifiers, prepare the table for the transfer and force data flush to disk:

```
psql -d old_database -c "SELECT
    pg_transfer_freeze('table_name'::regclass::oid, reltoastrelid::oid);"
```

### 3. Transfer the data to the target system

1. Copy the data into a separate directory using `pg_dump` utility:

```
pg_dump -Fc -t table_name --transfer-dir transfer_dir/ -f transfer_dir/
archive.out old_database
```

2. Restore the data in the target database:

```
pg_restore -d new_database --data-only --transfer-dir transfer_dir/ --copy-mode-
transfer transfer_dir/archive.out
```

When source and target databases are located in the same file system, the `--copy-mode-transfer` option must be specified at least once (for either `pg_dump` or `pg_restore` command) to get an independent copy of data. When restoring data on the primary server, `--generate-wal` option must be specified for `pg_restore` for changes to be replicated to a standby server.

## F.45.3. Compatibility

The `pg_transfer` extension is only supported on Linux systems.

## F.45.4. Authors

Postgres Professional, Moscow, Russia

## F.46. pg\_trgm

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

## F.46.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

### Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string "cat" is " c", " ca", "cat", and "at ". The set of trigrams in the string "foo|bar" is " f", " fo", "foo", "oo ", " b", " ba", "bar", and "ar ".

## F.46.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.35](#), the operators in [Table F.36](#).

**Table F.35. `pg_trgm` Functions**

| Function                                        | Returns              | Description                                                                                                                                                                                                                                                                         |
|-------------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>similarity(text, text)</code>             | real                 | Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).                                                              |
| <code>show_trgm(text)</code>                    | <code>text []</code> | Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)                                                                                                                                                                 |
| <code>word_similarity(text, text)</code>        | real                 | Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.                                                       |
| <code>strict_word_similarity(text, text)</code> | real                 | Same as <code>word_similarity(text, text)</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string. |
| <code>show_limit()</code>                       | real                 | Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity                                                                                                                                                                      |

| Function                     | Returns | Description                                                                                                                                                                                        |
|------------------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                              |         | between two words for them to be considered similar enough to be misspellings of each other, for example ( <i>deprecated</i> ).                                                                    |
| <code>set_limit(real)</code> | real    | Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in ( <i>deprecated</i> ). |

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity(text, text)` selects an extent of words in the second string. In the example above, `strict_word_similarity(text, text)` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
(1 row)
```

Thus, the `strict_word_similarity(text, text)` function is useful for finding the similarity to whole words, while `word_similarity(text, text)` is more suitable for finding the similarity for parts of words.

**Table F.36. pg\_trgm Operators**

| Operator                     | Returns | Description                                                                                                                                                                                                               |
|------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>text % text</code>     | boolean | Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .                                                     |
| <code>text &lt;% text</code> | boolean | Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold. |

| Operator                                 | Returns | Description                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          |         | set by <code>pg_trgm.word_similarity_threshold</code> parameter.                                                                                                                                                                                                                                                                      |
| <code>text %&gt; text</code>             | boolean | Commutator of the <code>&lt;%</code> operator.                                                                                                                                                                                                                                                                                        |
| <code>text &lt;&lt;% text</code>         | boolean | Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter. |
| <code>text %&gt;&gt; text</code>         | boolean | Commutator of the <code>&lt;&lt;%</code> operator.                                                                                                                                                                                                                                                                                    |
| <code>text &lt;-&gt; text</code>         | real    | Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.                                                                                                                                                                                                                                  |
| <code>text &lt;&lt;-&gt; text</code>     | real    | Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.                                                                                                                                                                                                                             |
| <code>text &lt;-&gt;&gt; text</code>     | real    | Commutator of the <code>&lt;&lt;-&gt;</code> operator.                                                                                                                                                                                                                                                                                |
| <code>text &lt;&lt;&lt;-&gt; text</code> | real    | Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.                                                                                                                                                                                                                      |
| <code>text &lt;-&gt;&gt;&gt; text</code> | real    | Commutator of the <code>&lt;&lt;&lt;-&gt;</code> operator.                                                                                                                                                                                                                                                                            |

### F.46.3. GUC Parameters

`pg_trgm.similarity_threshold` (real)

Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold` (real)

Sets the current word similarity threshold that is used by the `<%` and `%>` operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold` (real)

Sets the current strict word similarity threshold that is used by the `<<%` and `%>>` operators. The threshold must be between 0 and 1 (default is 0.5).

### F.46.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (~ and ~\* operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

## F.46.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

### Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

## F.47. pg\_tsparser

`pg_tsparser` is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word.

### F.47.1. Installation and Setup

`pg_tsparser` is included into the Postgres Pro distribution. To enable `pg_tsparser`, once Postgres Pro is installed, create the `pg_tsparser` extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once `pg_tsparser` is enabled, you can create your own text search configuration. In addition to `pg_tsparser`, you can use any available dictionary.

For example, you can create `english_ts` configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (  
    PARSER = tsparser  
);
```

```
COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for  
english language';
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,  
    numhword, numword, sfloat, uint, url, url_path, version  
    WITH simple;
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,  
    word, hword, hword_part  
    WITH english_stem;
```

### F.47.2. Examples

The following examples illustrate the difference in search results returned by `pg_tsparser` and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,  
       to_tsvector('english_ts', 'pg_trgm') as new_parser;  
def_parser | new_parser  
-----+-----  
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3  
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,  
       to_tsvector('english_ts', '123-abc') as new_parser;  
def_parser | new_parser  
-----+-----  
'123':1 'abc':2 | '123':2 '123-abc':1 'abc':3  
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,  
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;  
def_parser | new_parser  
-----+-----  
'-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1  
(1 row)
```

## F.47.3. Authors

Postgres Professional, Moscow, Russia

## F.48. pg\_variables

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

### Note

This extension cannot be used together with autonomous transactions or while built-in connection pooling is enabled.

### F.48.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the [CREATE EXTENSION](#) command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

### F.48.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.48.3.1](#) describes functions for scalar variables.
- [Section F.48.3.2](#) describes functions for record variables.
- [Section F.48.3.3](#) describes functions for array variables.
- [Section F.48.3.4](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.48.4](#).

#### F.48.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```
SELECT pgv_set('vars', 'int1', 101);  
BEGIN;  
SELECT pgv_set('vars', 'int2', 102);  
ROLLBACK;  
  
SELECT * FROM pgv_list() order by package, name;
```

```
package | name | is_transactional
-----+-----+-----
vars    | int1 | f
vars    | int2 | f
```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```
BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
pgv_get
-----
101
```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```
SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);
```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```
SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
package | name | is_transactional
-----+-----+-----
pack    | var_trans | t
```

## F.48.3. Functions

### F.48.3.1. Scalar Variables

The following functions support scalar variables:

| Function                                                                                             | Returns    |
|------------------------------------------------------------------------------------------------------|------------|
| <code>pgv_set(package text, name text, value anyonarray, is_transactional bool default false)</code> | void       |
| <code>pgv_get(package text, name text, var_type anyonarray, strict bool default true)</code>         | anyonarray |

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized package "vars"
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR:  unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR:  variable "int1" requires "integer" value
```

### F.48.3.2. Records

The following functions support collections of record variables:

| Function                                                                                        | Returns        | Description                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code> | void           | Inserts a record into a variable collection for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this variable collection has another structure, an error is raised. |
| <code>pgv_update(package text, name text, r record)</code>                                      | boolean        | Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this variable collection has another structure, an error is raised.                                                                                            |
| <code>pgv_delete(package text, name text, value anynonarray)</code>                             | boolean        | Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found.                                                                                                                                                                   |
| <code>pgv_select(package text, name text)</code>                                                | set of records | Returns the variable collection records.                                                                                                                                                                                                                                                                                          |
| <code>pgv_select(package text, name text, value anynonarray)</code>                             | record         | Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).                                                                                                                                                                                                                      |
| <code>pgv_select(package text, name text, value anyarray)</code>                                | set of records | Returns the variable collection records with the corresponding primary keys (the first column of <code>r</code> is a primary key).                                                                                                                                                                                                |

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

### F.48.3.3. Arrays

The following functions support array variables:

| Function                                                                                           | Returns  |
|----------------------------------------------------------------------------------------------------|----------|
| <code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code> | void     |
| <code>pgv_get(package text, name text, var_type anyarray, strict bool default true)</code>         | anyarray |

Usage instructions for these functions are the same as those provided in [Section F.48.3.1](#) for scalar variables.

#### F.48.3.4. Miscellaneous Functions

| Function                                         | Returns                                                            | Description                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pgv_exists(package text, name text)</code> | bool                                                               | Returns <code>true</code> if the specified package and variable exist.                                                                                                                                                                                                                             |
| <code>pgv_exists(package text)</code>            | bool                                                               | Returns <code>true</code> if the specified package exists.                                                                                                                                                                                                                                         |
| <code>pgv_remove(package text, name text)</code> | void                                                               | Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.                                                                                                                                                                        |
| <code>pgv_remove(package text)</code>            | void                                                               | Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.                                                                                                                                                                |
| <code>pgv_free()</code>                          | void                                                               | Removes all packages and variables.                                                                                                                                                                                                                                                                |
| <code>pgv_list()</code>                          | <code>table(package text, name text, is_transactional bool)</code> | Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.                                                                                                                                                                            |
| <code>pgv_stats()</code>                         | <code>table(package text, allocated_memory bigint)</code>          | Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher. |

#### F.48.3.5. Deprecated Functions

##### F.48.3.5.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                          | Returns |
|---------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code> | void    |
| <code>pgv_get_int(package text, name text, strict bool default true)</code>                       | int     |

**F.48.3.5.2. Text Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                            | Returns |
|-----------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code> | void    |
| <code>pgv_get_text(package text, name text, strict bool default true)</code>                        | text    |

**F.48.3.5.3. Numeric Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                  | Returns |
|-----------------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code> | void    |
| <code>pgv_get_numeric(package text, name text, strict bool default true)</code>                           | numeric |

**F.48.3.5.4. Timestamp Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                      | Returns   |
|---------------------------------------------------------------------------------------------------------------|-----------|
| <code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code> | void      |
| <code>pgv_get_timestamp(package text, name text, strict bool default true)</code>                             | timestamp |

**F.48.3.5.5. Timestamp with timezone Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                                          | Returns     |
|-------------------------------------------------------------------------------------------------------------------|-------------|
| <code>pgv_set_timestamptz(package text, name text, value timestamptz, is_transactional bool default false)</code> | void        |
| <code>pgv_get_timestamptz(package text, name text, strict bool default true)</code>                               | timestamptz |

**F.48.3.5.6. Date Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                            | Returns |
|-----------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code> | void    |
| <code>pgv_get_date(package text, name text, strict bool default true)</code>                        | date    |

**F.48.3.5.7. Jsonb Variables**

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

| Function                                                                                              | Returns |
|-------------------------------------------------------------------------------------------------------|---------|
| <code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code> | void    |
| <code>pgv_get_jsonb(package text, name text, strict bool default true)</code>                         | jsonb   |

## F.48.4. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
-----
      101
```

```
SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102
```

```
SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;
```

```
SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1,str11)
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1,str11)
```

```
SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0,str00)
```

```
SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
```

```

-----
(1,str11)
(0,str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0,str00)

```

**Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:**

```

SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
pgv_get
-----
before transaction block

```

**If you create a variable after `BEGIN` or `SAVEPOINT` statements and then rollback to the previous state, the transactional variable is removed:**

```

BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
pgv_get
-----
122

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR: unrecognized variable "var_int"
COMMIT;

```

**List the available packages and variables:**

```

SELECT * FROM pgv_list() ORDER BY package, name;
package | name | is_transactional

```

```
-----+-----+-----
pack    | var_text | t
vars    | int1     | f
vars    | int2     | f
vars    | r1       | f
vars    | text1    | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
package | allocated_memory
-----+-----
pack    |                16384
vars    |                32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

## F.48.5. Authors

Postgres Professional, Moscow, Russia

## F.49. pg\_visibility

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

### F.49.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

## F.50. `pg_wait_sampling`

`pg_wait_sampling` is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Enterprise provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time, per wait event type.
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that take longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 28.4](#).

**See Also**

## Viewing Statistics on Wait Events

### Reference

#### F.50.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Enterprise and requires no special prerequisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since `pg_wait_sampling` requires additional shared memory and launches a background worker, you must restart the server after adding or removing `pg_wait_sampling`.

Once the extension is created, `pg_wait_sampling` starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the `pg_wait_sampling` extension, remove the `pg_wait_sampling` from the `shared_preload_libraries` variable, and restart the server again.

#### F.50.2. Usage

##### F.50.2.1. Viewing Statistics on Wait Events

When `pg_wait_sampling` is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the `pg_wait_sampling_current` view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

## Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

## F.50.3. Reference

### F.50.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. You must have superuser rights to change GUC variables. Since these variables are placed into shared memory, you can change them from any backend that affects the `pg_wait_sampling` background worker runtime.

`pg_wait_sampling.history_size (int4)`

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period (int4)`

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period (int4)`

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid (int4)`

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

### F.50.3.2. `pg_wait_sampling` Views

#### F.50.3.2.1. `pg_wait_sampling_current` View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

**Table F.37. `pg_wait_sampling_current` View**

| Column Name             | Column Type       | Description             |
|-------------------------|-------------------|-------------------------|
| <code>pid</code>        | <code>int4</code> | Process ID              |
| <code>event_type</code> | <code>text</code> | Name of wait event type |
| <code>event</code>      | <code>text</code> | Name of wait event      |

**F.50.3.2.2. pg\_wait\_sampling\_history View**

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

**Table F.38. pg\_wait\_sampling\_history View**

| Column Name             | Column Type             | Description             |
|-------------------------|-------------------------|-------------------------|
| <code>pid</code>        | <code>int4</code>       | Process ID              |
| <code>ts</code>         | <code>timestampz</code> | Sample timestamp        |
| <code>event_type</code> | <code>text</code>       | Name of wait event type |
| <code>event</code>      | <code>text</code>       | Name of wait event      |

**F.50.3.2.3. pg\_wait\_sampling\_profile View**

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

**Table F.39. pg\_wait\_sampling\_profile View**

| Column Name             | Column Type       | Description             |
|-------------------------|-------------------|-------------------------|
| <code>pid</code>        | <code>int4</code> | Process ID              |
| <code>event_type</code> | <code>text</code> | Name of wait event type |
| <code>event</code>      | <code>text</code> | Name of wait event      |
| <code>count</code>      | <code>text</code> | Number of samples       |

**F.50.3.3. Functions**

```
pg_wait_sampling_get_current(pid int4)
```

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the `pid` argument, the view is filtered for the process with this `pid`.

Arguments:

- `pid` — Optional. The process ID for which to display the current wait events.

```
pg_wait_sampling_reset_profile()
```

Resets the waits profile and clears the memory.

**F.50.4. Author**

Alexander Korotkov

**F.51. plantuner**

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

**F.51.1. Motivation**

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plan-`

`tuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

## F.51.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

## F.51.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column | Type   | Modifiers
-----+-----+-----
   id    | integer |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
          Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
          Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
```

---

```
Index Cond: (id = 1)
(4 rows)
```

## F.52. postgres\_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older `dblink` module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using `CREATE EXTENSION`.
2. Create a foreign server object, using `CREATE SERVER`, to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using `CREATE USER MAPPING`, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using `CREATE FOREIGN TABLE` or `IMPORT FOREIGN SCHEMA`, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, or `COPY`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated later.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

### F.52.1. FDW Options of postgres\_fdw

#### F.52.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 35.1.2](#), except that these options are not allowed:

- `user` and `password` (specify these in a user mapping, instead)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

### F.52.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

### F.52.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

#### F.52.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions`

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

#### F.52.1.5. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

#### F.52.1.6. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

#### `import_default`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

#### `import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support `CHECK` constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a `CHECK` constraint could lead to hard-to-detect errors in query optimization. So if you wish to import `CHECK` constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of `CHECK` constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are automatically excluded. Partitioned tables are imported, unless they are a partition of some other table. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, this approach should allow access to all the data without creating extra objects.

## F.52.2. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

## F.52.3. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

## F.52.4. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE`

query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

### F.52.5. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

### F.52.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

### F.52.7. GUC Variables

`postgres_fdw.use_twophase` (boolean)

Enables two-phase commit (2PC) transactions. If this variable is set to `true`, each transaction must be *prepared* on all nodes before the commit. A successful `PREPARE` on the node means that this node is ready to commit the transaction, but it will only be committed if all other nodes can commit this transaction as well. Otherwise, the transaction will be aborted. This approach allows to ensure data consistency across all nodes.

Default: `false`

```
postgres_fdw.use_global_snapshots (boolean)
```

Enables/disables global snapshots for the current transaction if [track\\_global\\_snapshots](#) is set to `true`. This setting can be changed at any time, its value is consulted during transaction commit.

Default: `false`

## F.52.8. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
  FOREIGN DATA WRAPPER postgres_fdw
  OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
  SERVER foreign_server
  OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
  id integer NOT NULL,
  data text
)
  SERVER foreign_server
  OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of [IMPORT FOREIGN SCHEMA](#) is preferable to constructing foreign table definitions manually.

## F.52.9. Author

Shigeru Hanada <[shigeru.hanada@gmail.com](mailto:shigeru.hanada@gmail.com)>

## F.53. ptrack

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like [pg\\_probackup](#) can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

### F.53.1. Setting up PTRACK

Once you complete Postgres Pro Enterprise installation, do the following:

1. Add `ptrack` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set `ptrack.map_size` parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with  $N > 1$  TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the `wal_level` setting. When using PTRACK, it is required to set the `wal_level` parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.
4. Restart the Postgres Pro Enterprise instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

### Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

## F.53.2. PTRACK Configuration Parameters

`ptrack.map_size (integer)`

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The -1 value disables PTRACK, while the 0 value both disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: -1

## F.53.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(start_lsn pg_lsn)` returns setof record

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
      path      | pagecount |          pagemap
-----+-----+-----
base/16384/1255 |         3 | \x001000000005000000000000
base/16384/2674 |         3 | \x0000000900010000000000000000
base/16384/2691 |         1 | \x0000400000000000000000000000
base/16384/2608 |         1 | \x0000000000000000400000000000000000
base/16384/2690 |         1 | \x00040000000000000000000000
```

`ptrack_get_change_stat(start_lsn pg_lsn)` returns record

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
 files | pages |      size, MB
-----+-----+-----
    20 |    25 | 0.19531250000000000000
```

`ptrack_version()` returns text

Returns PTRACK version.

## F.54. referee

`referee` is a Postgres Pro Enterprise extension for managing quorum settings in clusters with an even number of nodes configured with [multimaster](#). Installed on a separate system, the `referee` extension provides a voting node to assign the quorum status to a subset of nodes if only half of the cluster nodes remain connected to each other.

If a multi-master cluster is split into equal parts, or half of the cluster nodes fail, each subset of nodes that equals half of the cluster tries to access the referee. The first subset that gets connected to the referee wins the voting and continues working, while all the other nodes are excluded from the cluster to avoid split-brain problems.

The referee node does not store any cluster data, so it is very lightweight and can be located on systems with limited resources. For details on how to set up and use a referee node with `multimaster`, see [Section F.30.3.3](#).

## F.55. rum

### F.55.1. Introduction

The **rum** module provides access method to work with the RUM indexes. It is based on the GIN access methods code.

GIN index allows to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with GIN index has the following drawbacks:

- Slow ranking. Ranking requires positional information, but `GIN` index does not store positions of lexemes. So after the index scan we need an additional heap scan to retrieve lexeme positions.
- Slow phrase search. This problem is related to the previous one as phrase search also needs positional information.
- Slow ordering by timestamp. `GIN` index cannot store any additional information together with lexemes, so it is necessary to perform a heap scan.

`RUM` solves these issues by storing additional information in posting tree. In particular, it stores positional information of lexemes or timestamps.

The drawback of `RUM` is that it has slower build and insert time as compared to `GIN` because `RUM` stores additional information together with keys and uses generic WAL records.

## F.55.2. Installation

`rum` is a Postgres Pro Enterprise extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

## F.55.3. Common Operators

The operators provided by the `rum` module are shown in [Table F.40](#):

**Table F.40.** `rum` Operators

| Operator                                   | Returns             | Description                                                                     |
|--------------------------------------------|---------------------|---------------------------------------------------------------------------------|
| <code>tsvector &lt;=&gt; tsquery</code>    | <code>float4</code> | Returns distance between <code>tsvector</code> and <code>tsquery</code> values. |
| <code>timestamp &lt;=&gt; timestamp</code> | <code>float8</code> | Returns distance between two timestamp values.                                  |
| <code>timestamp &lt;=  timestamp</code>    | <code>float8</code> | Returns distance only for ascending timestamp values.                           |
| <code>timestamp  =&gt; timestamp</code>    | <code>float8</code> | Returns distance only for descending timestamp values.                          |

## F.55.4. Operator Classes

The `rum` extension provides the following operator classes:

`rum_tsvector_ops`

Stores `tsvector` lexemes with positional information. Supports ordering by `<=>` operator and prefix search.

`rum_tsvector_hash_ops`

Stores hash of `tsvector` lexemes with positional information. Supports ordering by `<=>` operator, but does not support prefix search.

`rum_tsvector_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`.

`rum_tsvector_hash_addon_ops`

Stores `tsvector` lexemes with additional data of any type supported by `RUM`. Does not support prefix search.

`rum_tsquery_ops`

Stores branches of query tree in additional information.

`rum_anyarray_ops`

Stores `anyarray` elements with length of the array. Supports ordering by `<=>` operator.

Indexable operators: `&&` `@>` `<@` `=` `%`

`rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by RUM.

`rum_type_ops`

Stores lexemes of the corresponding type with positional information. The `type` placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`, `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.
- `<` `<=` `=` `>=` `>` are supported for `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

### Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestampz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestampz_ops`.

## F.55.5. Examples

### F.55.5.1. `rum_tsvector_ops` Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
      t | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```
SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
      t | rank
-----+-----
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)
```

### F.55.5.2. rum\_tsvector\_addon\_ops Example

Let's assume we have the following table:

```
CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'

CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
WITH (attach = 'd', to = 't');
```

Now we can execute the following queries:

```
EXPLAIN (costs off)
  SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
  <=> '2016-05-16 14:21:25' LIMIT 5;
      QUERY PLAN
-----
Limit
->  Index Scan using tsts_idx on tsts
      Index Cond: (t @@ '''wr' & 'qh''':tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016':timestamp without time zone)
(4 rows)
```

```
SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
'2016-05-16 14:21:25' LIMIT 5;
 id | d | ?column?
-----+-----+-----
355 | Mon May 16 14:21:22.326724 2016 | 2.673276
354 | Mon May 16 13:21:22.326724 2016 | 3602.673276
371 | Tue May 17 06:21:22.326724 2016 | 57597.326724
406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)
```

### F.55.5.3. rum\_tsquery\_ops Example

Suppose we have the table:

```
CREATE TABLE query (q tsquery, tag text);
```

```
INSERT INTO query VALUES ('supernova & star', 'sn'),
    ('black', 'color'),
    ('big & bang & black & hole', 'bang'),
    ('spiral & galaxy', 'shape'),
    ('black & hole', 'color');
```

```
CREATE INDEX query_idx ON query USING rum(q);
```

We can execute the following fast query:

```
SELECT * FROM query
    WHERE to_tsvector('black holes never exists before we think about them') @@ q;
      q          | tag
-----+-----
'black'          | color
'black' & 'hole' | color
(2 rows)
```

#### F.55.5.4. rum\_anyarray\_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
    ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      i
-----
{1}
{1,2}
{1,2,3}
{1,2,3,4}
(4 rows)
```

### F.56. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

### F.56.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
      pH
-----
6.25 .. 6.50
(1 row)
```

### F.56.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.41](#) gives an overview of allowed representations; [Table F.42](#) shows some examples.

In [Table F.41](#), *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

**Table F.41. `seg` External Representations**

|                            |                                                                  |
|----------------------------|------------------------------------------------------------------|
| <i>x</i>                   | Single value (zero-length interval)                              |
| <i>x</i> .. <i>y</i>       | Interval from <i>x</i> to <i>y</i>                               |
| <i>x</i> (+-) <i>delta</i> | Interval from <i>x</i> - <i>delta</i> to <i>x</i> + <i>delta</i> |
| <i>x</i> ..                | Open interval with lower bound <i>x</i>                          |
| .. <i>x</i>                | Open interval with upper bound <i>x</i>                          |

**Table F.42. Examples of Valid `seg` Input**

|                |                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 5.0            | Creates a zero-length segment (a point, if you will)                                                                                 |
| ~5.0           | Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment. |
| <5.0           | Creates a point at 5.0. < is ignored but is preserved as a comment.                                                                  |
| >5.0           | Creates a point at 5.0. > is ignored but is preserved as a comment.                                                                  |
| 5(+-)0.3       | Creates an interval 4.7 .. 5.3. Note that the (+-) notation isn't preserved.                                                         |
| 50 ..          | Everything that is greater than or equal to 50                                                                                       |
| .. 0           | Everything that is less than or equal to 0                                                                                           |
| 1.5e-2 .. 2E-2 | Creates an interval 0.015 .. 0.02                                                                                                    |
| 1 ... 2        | The same as 1...2, or 1 .. 2, or 1..2 (spaces around the range operator are ignored)                                                 |

Because the `...` operator is widely used in data sources, it is allowed as an alternative spelling of the `..` operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0...23` is meant to be `23` or `0.23`. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 .. 2`.

### F.56.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns `0.00`, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value `0.0067` is considered to have just 2 significant digits.

### F.56.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.43](#).

**Table F.43. Seg GiST Operators**

| Operator                             | Description                                                                                                                                                              |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>[a, b] &lt;&lt; [c, d]</code>  | <code>[a, b]</code> is entirely to the left of <code>[c, d]</code> . That is, <code>[a, b] &lt;&lt; [c, d]</code> is true if <code>b &lt; c</code> and false otherwise.  |
| <code>[a, b] &gt;&gt; [c, d]</code>  | <code>[a, b]</code> is entirely to the right of <code>[c, d]</code> . That is, <code>[a, b] &gt;&gt; [c, d]</code> is true if <code>a &gt; d</code> and false otherwise. |
| <code>[a, b] &amp;&lt; [c, d]</code> | Overlaps or is left of — This might be better read as “does not extend to right of”. It is true when <code>b &lt;= d</code> .                                            |
| <code>[a, b] &amp;&gt; [c, d]</code> | Overlaps or is right of — This might be better read as “does not extend to left of”. It is true when <code>a &gt;= c</code> .                                            |
| <code>[a, b] = [c, d]</code>         | Same as — The segments <code>[a, b]</code> and <code>[c, d]</code> are identical, that is, <code>a = c</code> and <code>b = d</code> .                                   |

| Operator                              | Description                                                                                                                             |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>[a, b] &amp;&amp; [c, d]</code> | The segments <code>[a, b]</code> and <code>[c, d]</code> overlap.                                                                       |
| <code>[a, b] @&gt; [c, d]</code>      | The segment <code>[a, b]</code> contains the segment <code>[c, d]</code> , that is, <code>a &lt;= c</code> and <code>b &gt;= d</code> . |
| <code>[a, b] &lt;@ [c, d]</code>      | The segment <code>[a, b]</code> is contained in <code>[c, d]</code> , that is, <code>a &gt;= c</code> and <code>b &lt;= d</code> .      |

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The standard B-tree operators are also provided, for example

| Operator                        | Description  |
|---------------------------------|--------------|
| <code>[a, b] &lt; [c, d]</code> | Less than    |
| <code>[a, b] &gt; [c, d]</code> | Greater than |

These operators do not make a lot of sense for any practical purpose but sorting. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

## F.56.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

## F.56.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

## F.57. shared\_ispell

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

## F.57.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.44](#).

**Table F.44. `shared_ispell` Functions**

| Function                                   | Returns                                                                                      | Description                                                                                                                                                            |
|--------------------------------------------|----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>shared_ispell_reset()</code>         | <code>void</code>                                                                            | Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them. |
| <code>shared_ispell_mem_used()</code>      | <code>int</code>                                                                             | Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.                                                                           |
| <code>shared_ispell_mem_available()</code> | <code>int</code>                                                                             | Returns a value of available memory of the shared segment.                                                                                                             |
| <code>shared_ispell_dicts()</code>         | <code>setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)</code> | Returns a list of dictionaries loaded in the shared segment.                                                                                                           |
| <code>shared_ispell_stoplists()</code>     | <code>setof(stop_name varchar, words int, bytes int)</code>                                  | Returns a list of stopwords loaded in the shared segment.                                                                                                              |

## F.57.2. GUC Parameters

`shared_ispell.max_size (int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

## F.57.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);
```

```
CREATE TEXT SEARCH CONFIGURATION public.english_shared
( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                    word, hword, hword_part
  WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
  alias  | description | token | dictionaries | dictionary
  | lexemes
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
asciiword | Word, all ASCII | abilities | {english_shared,english_stem} |
english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
  ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                    word, hword, hword_part
  WITH english_shared, english_stem;
```

## F.58. spi

The `spi` module provides several workable examples of using the [Server Programming Interface \(SPI\)](#) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

### F.58.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

## F.58.2. **timetravel** — Functions for Implementing Time Travel

Long ago, Postgres Pro had a built-in time travel feature that kept the insert and delete times for each tuple. This can be emulated using these functions. To use these functions, you must add to a table two columns of `abstime` type to store the date when a tuple was inserted (`start_date`) and changed/deleted (`stop_date`):

```
CREATE TABLE mytab (
    ...
    start_date      abstime,
    stop_date       abstime
    ...
);
```

The columns can be named whatever you like, but in this discussion we'll call them `start_date` and `stop_date`.

When a new row is inserted, `start_date` should normally be set to current time, and `stop_date` to `infinity`. The trigger will automatically substitute these values if the inserted data contains nulls in these columns. Generally, inserting explicit non-null data in these columns should only be done when re-loading dumped data.

Tuples with `stop_date` equal to `infinity` are “valid now”, and can be modified. Tuples with a finite `stop_date` cannot be modified anymore — the trigger will prevent it. (If you need to do that, you can turn off time travel as shown below.)

For a modifiable row, on update only the `stop_date` in the tuple being updated will be changed (to current time) and a new tuple with the modified data will be inserted. `Start_date` in this new tuple will be set to current time and `stop_date` to `infinity`.

A delete does not actually remove the tuple but only sets its `stop_date` to current time.

To query for tuples “valid now”, include `stop_date = 'infinity'` in the query's WHERE condition. (You might wish to incorporate that in a view.) Similarly, you can query for tuples valid at any past time with suitable conditions on `start_date` and `stop_date`.

`timetravel()` is the general trigger function that supports this behavior. Create a `BEFORE INSERT OR UPDATE OR DELETE` trigger using this function on each time-traveled table. Specify two trigger arguments: the actual names of the `start_date` and `stop_date` columns. Optionally, you can specify one to three more arguments, which must refer to columns of type `text`. The trigger will store the name of the current user into the first of these columns during `INSERT`, the second column during `UPDATE`, and the third during `DELETE`.

`set_timetravel()` allows you to turn time-travel on or off for a table. `set_timetravel('mytab', 1)` will turn TT ON for table `mytab`. `set_timetravel('mytab', 0)` will turn TT OFF for table `mytab`. In both cases the old status is reported. While TT is off, you can modify the `start_date` and `stop_date` columns freely. Note that the on/off status is local to the current database session — fresh sessions will always start out with TT ON for all tables.

`get_timetravel()` returns the TT state for a table without changing it.

There is an example in `timetravel.example`.

## F.58.3. **autoinc** — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

### F.58.4. `insert_username` — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

### F.58.5. `moddatetime` — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

## F.59. `sr_plan`

### Important

The `sr_plan` extension is no longer supported in Postgres Pro.

### F.59.1. Rationale

`sr_plan` is an extension which allows to save query execution plans and use these plans for all repetitions of same query, instead of optimizing identical query again and again.

`sr_plan` looks like Oracle Outline system. It can be used to lock the execution plan. It is necessary if you do not trust the planner or able to form a better plan.

Typically, DBA would play with queries interactively, and save their plans and then enable use of saved plans for the queries, where predictable response time is essential.

Then application which uses these queries would use saved plans.

### F.59.2. Installation

In your db:

```
CREATE EXTENSION sr_plan;
```

and modify your `postgresql.conf`:

```
shared_preload_libraries = 'sr_plan'
```

It is essential that library is preloaded during server startup, because use of saved plans is enabled on per-database basis and doesn't require any per-connection actions.

### F.59.3. Usage

If you want to save the query plan is necessary to set the variable:

```
set sr_plan.write_mode = true;
```

Now plans for all subsequent queries will be stored in the table `sr_plans`, until this variable is set to false. Don't forget that all queries will be stored including duplicates. Making an example query:

```
select query_hash from sr_plans where query_hash=10;
```

Disable saving the query:

```
set sr_plan.write_mode = false;
```

Now verify that your query is saved:

```
select query_hash, enable, valid, query, explain_jsonb_plan(plan) from sr_plans;
```

| query_hash | enable | valid | query                                                | explain_jsonb_plan                                                                                                                                  |
|------------|--------|-------|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 1783086253 | f      | t     | select query_hash from sr_plans where query_hash=10; | Bitmap Heap Scan on sr_plans<br>Recheck Cond: (query_hash = 10)<br>-> Bitmap Index Scan on sr_plans_query_hash_idx<br>Index Cond: (query_hash = 10) |

Note use of `explain_jsonb_plan` function, that allows you to visualize execution plan in the similar way as EXPLAIN command does.

In the database plans are stored as jsonb. By default, all the newly saved plans are disabled, you need enable it manually:

To enable use of the saved plan

```
update sr_plans set enable=true where query_hash=1783086253;
```

(1783086253 for example only) After that, the plan for the query will be taken from the `sr_plans` table.

In addition sr plan allows you to save a parameterized query plan. In this case, we have some constants in the query that, as we know, do not affect plan.

During plan saving mode we can mark these constants as query parameters using a special function `_p` (anyelement). For example:

```
=>create table test_table (a numeric, b text);
CREATE TABLE
=>insert into test_table values (1,'1'), (2,'2'), (3,'3');
INSERT 0 3
=> set sr_plan.write_mode = true;
SET
=> select a,b from test_table where a = _p(1);
a | b
```

```
---+---
1 | 1
(1 row)
```

```
=> set sr_plan.write_mode = false;
SET
```

Now plan for query from our table is saved with parameter. So, if we enable saved plan in this table, this plan would be used for query with any value for a, as long as this value is wrapped with `_p()` function.

```
=> update sr_plans set enable = true where query=
      'select a,b from test_table where a = _p(1)';
UPDATE 1
-- These queries would use saved plan
```

```
=> select a,b from test_table where a = _p(2);
 a | b
---+---
 2 | 2
(1 row)
```

```
=> select a,b from test_table where a = _p(3);
 a | b
---+---
 3 | 3
(1 row)
```

```
-- This query wouldn't use saved plan, because constant is not wrapped
-- with _p()
```

```
=> select a,b from test_table where a = 1;
 a | b
---+---
 1 | 1
(1 row)
```

## F.60. sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

This extension won't build at all unless the installation was configured with `--with-openssl`.

### F.60.1. Functions Provided

`ssl_is_used()` returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, or TLSv1.2).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL\_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

## F.61. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

### F.61.1. Functions Provided

Table F.45 shows the functions provided by the `tablefunc` module.

**Table F.45. tablefunc Functions**

| Function                                                                                                                                                 | Returns                        | Description                                                                                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>normal_rand(int numvals, float8 mean, float8 stddev)</code>                                                                                        | setof float8                   | Produces a set of normally distributed random values                                                                                                                                                                                                      |
| <code>crosstab(text sql)</code>                                                                                                                          | setof record                   | Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query                                                                                                    |
| <code>crosstabN(text sql)</code>                                                                                                                         | setof table_crosstab_ <i>N</i> | Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below |
| <code>crosstab(text source_sql, text category_sql)</code>                                                                                                | setof record                   | Produces a “pivot table” with the value columns specified by a second query                                                                                                                                                                               |
| <code>crosstab(text sql, int N)</code>                                                                                                                   | setof record                   | Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query                                                                                      |
| <code>connectby(text relname, text keyid_fld, text parent_keyid_fld [, text orderby_fld ], text start_with, int max_depth [, text branch_delim ])</code> | setof record                   | Produces a representation of a hierarchical tree structure                                                                                                                                                                                                |

#### F.61.1.1. normal\_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns setof float8

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

`numvals` is the number of values to be returned from the function. `mean` is the mean of the normal distribution of values and `stdev` is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
      normal_rand
-----
      1.56556322244898
      9.10040991424657

#### F.61.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

| row_name | cat  | value |
|----------|------|-------|
| row1     | cat1 | val1  |
| row1     | cat2 | val2  |
| row1     | cat3 | val3  |
| row1     | cat4 | val4  |
| row2     | cat1 | val5  |

|      |      |      |
|------|------|------|
| row2 | cat2 | val6 |
| row2 | cat3 | val7 |
| row2 | cat4 | val8 |

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

| <== value columns ==> |            |            |
|-----------------------|------------|------------|
| row_name              | category_1 | category_2 |
| row1                  | val1       | val2       |
| row2                  | val5       | val6       |

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N` `value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```
CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');
```

```
SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);
```

| row_name | category_1 | category_2 | category_3 |
|----------|------------|------------|------------|
| test1    | val2       | val3       |            |
| test2    | val6       | val7       |            |

(2 rows)

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

**Note**

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

**F.61.1.3. `crosstabN(text)`**

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (
    row_name TEXT,
    category_1 TEXT,
    category_2 TEXT,
    .
    .
    .
    category_N TEXT
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *
FROM crosstab3(
    'select rowid, attribute, value
    from ct
    where attribute = ''att2'' or attribute = ''att3''
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (
    my_row_name text,
    my_category_1 float8,
    my_category_2 float8,
    my_category_3 float8,
    my_category_4 float8,
    my_category_5 float8
);

CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)
    RETURNS setof my_crosstab_float8_5_cols
    AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(
```

```

    IN text,
    OUT my_row_name text,
    OUT my_category_1 float8,
    OUT my_category_2 float8,
    OUT my_category_3 float8,
    OUT my_category_4 float8,
    OUT my_category_5 float8)
    RETURNS setof record
    AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;

```

#### F.61.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

*source\_sql* is a SQL statement that produces the source set of data. This statement must return one *row\_name* column, one *category* column, and one *value* column. It may also have one or more “extra” columns. The *row\_name* column must be first. The *category* and *value* columns must be the last two columns, in that order. Any columns between *row\_name* and *category* are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same *row\_name* value.

For example, *source\_sql* might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

| row_name | extra_col | cat  | value |
|----------|-----------|------|-------|
| row1     | extra1    | cat1 | val1  |
| row1     | extra1    | cat2 | val2  |
| row1     | extra1    | cat4 | val4  |
| row2     | extra2    | cat1 | val5  |
| row2     | extra2    | cat2 | val6  |
| row2     | extra2    | cat3 | val7  |
| row2     | extra2    | cat4 | val8  |

*category\_sql* is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. *category\_sql* might be something like:

```

SELECT DISTINCT cat FROM foo ORDER BY 1;
   cat
-----
  cat1
  cat2
  cat3
  cat4

```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```

SELECT * FROM crosstab('...', '...')
    AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);

```

This will produce a result something like:

|          |       | <==  | value | columns | ==>  |
|----------|-------|------|-------|---------|------|
| row_name | extra | cat1 | cat2  | cat3    | cat4 |

```
-----+-----+-----+-----+-----+-----
row1      extra1  val1    val2              val4
row2      extra2  val5    val6    val7      val8
```

The `FROM` clause must define the proper number of output columns of the proper data types. If there are  $N$  columns in the `source_sql` query's result, the first  $N-2$  of them must match up with the first  $N-2$  output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output value columns are filled with the value fields from rows having matching category values. If a row's category does not match any output of the `category_sql` query, its value is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the `source_sql` query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the `category_sql` query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);
```

```
year | Jan | Feb | Mar | Apr | May | Jun | Jul | Aug | Sep | Oct | Nov | Dec
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
2007 | 1000 | 1500 |      |      |      |      | 500 |      |      |      | 1500 | 2000
2008 | 1000 |      |      |      |      |      |      |      |      |      |      |
(2 rows)
```

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
```

```

INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');

SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
)
AS
(
  rowid text,
  rowdt timestamp,
  temperature int4,
  test_result text,
  test_startdate timestamp,
  volts float8
);
 rowid |          rowdt          | temperature | test_result |      test_startdate
      | volts
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS      |
      | 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL      | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

#### F.61.1.5. `connectby`

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
          [, text orderby_fld ], text start_with, int max_depth
          [, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

[Table F.46](#) explains the parameters.

**Table F.46. `connectby` Parameters**

| Parameter               | Description                                              |
|-------------------------|----------------------------------------------------------|
| <i>relname</i>          | Name of the source relation                              |
| <i>keyid_fld</i>        | Name of the key field                                    |
| <i>parent_keyid_fld</i> | Name of the parent-key field                             |
| <i>orderby_fld</i>      | Name of the field to order siblings by (optional)        |
| <i>start_with</i>       | Key value of the row to start at                         |
| <i>max_depth</i>        | Maximum depth to descend to, or zero for unlimited depth |
| <i>branch_delim</i>     | String to separate keys with in branch output (optional) |

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start\_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
  AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a *branch\_delim* parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an *orderby\_fld* parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified *branch\_delim* string. If no branch display is wanted, omit both the *branch\_delim* parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the *orderby\_fld* parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if *orderby\_fld* is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the *branch\_delim* string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if *branch\_delim* is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);
```

```
INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
  AS t(keyid text, parent_keyid text, level int, branch text);
```

| keyid | parent_keyid | level | branch              |
|-------|--------------|-------|---------------------|
| row2  |              | 0     | row2                |
| row4  | row2         | 1     | row2~row4           |
| row6  | row4         | 2     | row2~row4~row6      |
| row8  | row6         | 3     | row2~row4~row6~row8 |
| row5  | row2         | 1     | row2~row5           |
| row9  | row5         | 2     | row2~row5~row9      |

(6 rows)

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
  AS t(keyid text, parent_keyid text, level int);
  keyid | parent_keyid | level
-----+-----+-----
row2   |              |      0
row4   | row2         |      1
row6   | row4         |      2
row8   | row6         |      3
row5   | row2         |      1
row9   | row5         |      2
(6 rows)
```

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
  '~')
  AS t(keyid text, parent_keyid text, level int, branch text, pos int);
  keyid | parent_keyid | level |      branch      | pos
-----+-----+-----+-----+-----
row2   |              |      0 | row2              | 1
row5   | row2         |      1 | row2~row5         | 2
row9   | row5         |      2 | row2~row5~row9    | 3
row4   | row2         |      1 | row2~row4         | 4
row6   | row4         |      2 | row2~row4~row6    | 5
row8   | row6         |      3 | row2~row4~row6~row8 | 6
(6 rows)
```

```
-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
  AS t(keyid text, parent_keyid text, level int, pos int);
  keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2   |              |      0 | 1
row5   | row2         |      1 | 2
row9   | row5         |      2 | 3
row4   | row2         |      1 | 4
row6   | row4         |      2 | 5
row8   | row6         |      3 | 6
(6 rows)
```

## F.61.2. Author

Joe Conway

## F.62. tcn

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER trigger FOR EACH ROW`.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=# (
test(#      a int not null,
test(#      b date not null,
test(#      c text,
test(#      primary key (a, b)
test(#      );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=# after insert or update or delete on tcndata
test=# for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                                     (1, date '2012-12-23', 'another'),
test=#                                     (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.

received from server process with PID 22770.
```

## F.63. test\_decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```
postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 location | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
```

(8 rows)

## F.64. tsm\_system\_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

### F.64.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

## F.65. tsm\_system\_time

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

### F.65.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

## F.66. unaccent

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

## F.66.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

|   |    |
|---|----|
| À | A  |
| Á | A  |
| Â | A  |
| Ã | A  |
| Ä | A  |
| Å | A  |
| Æ | AE |

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

## F.66.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
 ts_lexize
-----
 {Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
        to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
        ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
        ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

### F.66.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent`-type dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns text

If the `dictionary` argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

## F.67. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants.

### F.67.1. uuid-oss Functions

[Table F.47](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

**Table F.47. Functions for UUID Generation**

| Function                        | Description                                                                                                                                                                                                                                                                                                         |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_generate_v1()</code> | This function generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications. |

| Function                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_generate_v1mc()</code>                        | This function generates a version 1 UUID but uses a random multicast MAC address instead of the real MAC address of the computer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>uuid_generate_v3(namespace uuid, name text)</code> | <p>This function generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code>() functions shown in <a href="#">Table F.48</a>. (It could be any UUID in theory.) The name is an identifier in the selected namespace.</p> <p>For example:</p> <pre>SELECT uuid_generate_v3(uuid_ns_url(),   'http://www.postgresql.org');</pre> <p>The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.</p> |
| <code>uuid_generate_v4()</code>                          | This function generates a version 4 UUID, which is derived entirely from random numbers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>uuid_generate_v5(namespace uuid, name text)</code> | This function generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Table F.48. Functions Returning UUID Constants**

|                             |                                                                                                                                                                |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>uuid_nil()</code>     | A “nil” UUID constant, which does not occur as a real UUID.                                                                                                    |
| <code>uuid_ns_dns()</code>  | Constant designating the DNS namespace for UUIDs.                                                                                                              |
| <code>uuid_ns_url()</code>  | Constant designating the URL namespace for UUIDs.                                                                                                              |
| <code>uuid_ns_oid()</code>  | Constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.) |
| <code>uuid_ns_x500()</code> | Constant designating the X.500 distinguished name (DN) namespace for UUIDs.                                                                                    |

## F.67.2. Building `uuid-ossdp`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-ossdp` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suitable UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs'` `libuuid`, or `--with-uuid=ossdp` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

### Note

If you only need randomly-generated (version 4) UUIDs, consider using the `gen_random_uuid()` function from the [pgcrypto](#) module instead.

## F.67.3. Author

Peter Eisentraut <peter\_e@gmx.net>

## F.68. vops

The `vops` module is an experimental Postgres Pro Enterprise extension that provides support for vector operations, which allows to speed up OLAP queries with filtering and aggregation more than 10 times. Performance improvements are achieved by implementing a vertical data model that allows storing data in *tiles*, or groups of column values. Such a storage format is also called *Parquet* in some analytical databases. Reducing the overhead of unpacking tuples, vertical data model allows to speed up query execution without any radical changes in Postgres Pro planner and executor.

`vops` provides its own set of vector functions that can be used inside predicates and aggregate expressions. To avoid learning new syntax, you can use [postgres\\_fdw](#) as an abstraction layer and run regular SQL queries on vectorized data. For query types other than filtering and aggregation, `vops` can also use `postgres_fdw` to present vectorized data as a regular table with scalar column types and process this data as regular tuples. For ease of use, `vops` also provides an automated way of generating and accessing vectorized data, as explained in [Section F.68.5.5](#).

### F.68.1. Limitations

- Tile-based tables only allow `INSERT` and `APPEND` operations. Once imported, vectorized data cannot be updated.
- Vector operations are only available for filtering and aggregation. Other query types are supported via `postgres_fdw`.
- Aggregate expressions must be of the same type.
- `JOIN` operations are not supported for vector types. You have to use `postgres_fdw` to transform vectorized data back to regular tuples to run such queries.
- Since `postgres_fdw` does not support parallel query execution, you can only run parallel queries when using vector operators directly.

### F.68.2. Installation and Setup

The `vops` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `vops`:

1. Add `vops` to the [shared\\_preload\\_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'vops'
```

### Note

If the extension library is not added to the `shared_preload_libraries` list, it will be loaded on demand after the first function invocation of this extension. In this case, the first time you execute a vectorized query, it will not be processed correctly and can return a wrong result.

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.

### 3. Create `vops` extension:

```
CREATE EXTENSION vops;
```

Once `vops` is enabled, you can create vectorized tables and query data using vector operations in your database.

If you would like to use regular SQL syntax for vector types, you must also enable [postgres\\_fdw](#).

## F.68.3. Motivation

For OLTP workloads, Postgres Pro looks very competitive as compared to other mainstream databases. However, for OLAP queries, which require processing larger volumes of data, analytics-oriented database management systems can provide a much better speed. There are several main factors that limit Postgres Pro performance:

- **Tuple unpacking overhead.** To access column values, Postgres Pro needs to unpack the tuple. As tables can have columns of variable-length data types, to extract the N-th column, the preceding N-1 columns need to be unpacked. Thus, deforming a tuple is quite an expensive operation, especially for tables with a large number of attributes. Besides, values can be compressed or stored in another page (TOAST). In queries like Query 6 of the [TPC-H benchmark](#), deforming tuples takes about 40% of the total query execution time.
- **Interpretation overhead.** Postgres Pro planner and optimizer build a tree representing the query execution plan. Query executor recursively calls functions that evaluate the nodes of this tree. Some nodes may also contain switches used to select the requested action. Thus, query plan is interpreted by Postgres Pro query executor rather than directly executed. The interpreter is usually about 10 times slower than the native code. If you eliminate interpretation overhead, you can increase query speed several times, especially for queries with complex predicates that have high evaluation costs.
- **Abstraction penalty.** Support for abstract (user-defined) types and operations is one of the key features of Postgres Pro. However, the price of such flexibility is that each operation requires a separate function call. Instead of adding two integers directly, Postgres Pro executor invokes a function that performs addition. In this case, function call overhead is much higher than the cost the operation itself. Function call overhead is also increased because Postgres Pro requires passing parameter values through memory.
- **Pull model overhead.** In Postgres Pro, operators pull the operand values. This approach simplifies the implementation of operators and the executor, but has a negative impact on performance. In this model, leaf nodes that fetch a tuple from the heap or index pages have to do a lot of extra work while saving and restoring their context.
- **MVCC overhead.** Postgres Pro provides multi-version concurrency control, which allows multiple transactions to work with the same record in parallel without blocking each other. It is good for frequently updated data (OLTP), but for read-only or append-only data in OLAP scenarios it only adds both space overhead (about 20 extra bytes per tuple) and CPU overhead (checking visibility of each tuple).

Vector operations can address most of these issues without radical changes in the Postgres Pro executor, as explained in [Section F.68.4](#).

## F.68.4. Architecture

The `vops` extension implements a *vertical data model* for Postgres Pro. In this model, vertical columns are used as a data storing unit, with the values of the corresponding table attribute forming a vector.

The vertical data model used by `vops` has the following advantages:

- **Reduces the size of fetched data:** only the columns used in the query need to be fetched.
- **Achieves higher compression rates:** storing all values of the same attribute together makes it possible to compress them much better and faster. For example, you can use delta encoding.
- **Minimizes interpretation overhead:** a set of values can be processed by a single operation instead of running separate operations for each value.

- Uses CPU vector instructions (SIMD) to process data.

A traditional Postgres Pro query executor deals with a single row of data at each moment of time. For example, to evaluate an expression  $(x+y)$ , it first fetches the value of  $x$ , then fetches the value of  $y$ , performs the addition, and returns the result value to the upper node. In contrast, a vectorized executor can process multiple values within a single operation. In this case,  $x$  and  $y$  represent vectors of values instead of single scalars. The returned result is also a vector. In vector execution model, interpretation and function call overhead is divided by the vector size. The price of performing a function call is the same, but as the function processes  $N$  values instead of a single one, this overhead becomes less critical. The larger the vector, the smaller the per-row overhead.

However, performing an operation on the whole column may also turn out to be ineffective. Working with large vectors prevents efficient utilization of CPU cache levels. If the table is very large, the vector may not fit in memory at all. To avoid these issues, `vops` splits the columns into relatively small chunks, or *tiles*. The size of a tile is currently set to 64 elements. It allows to keep all operands of vector operations in cache, even for complex expressions.

The `vops` extension implements special vector types to be used instead of scalar types for table columns. The available types are listed in [Section F.68.6.1](#). To use `vops`, you have to create vectorized projections of original tables, with at least some attributes using these tile types, as explained in [Section F.68.5.1](#).

The original table can be treated as a write-optimized storage: if it has no indexes, Postgres Pro can provide a very fast insertion speed, comparable to raw disk write speed. Vectorized projection can be treated as a read-optimized storage, which is most efficient for running OLAP queries.

Once all the data is in the tile-based format, you can run vectorized queries on this data. `vops` provides a set of [vector operators](#) to work with vector types. Using these operators, you can write queries for filtering and aggregation, similar to SQL queries. For details, see [Section F.68.5.2](#).

For other query types, `vops` allows to work with vectorized data via `postgres_fdw`. You can add vectorized data to your database cluster as a foreign table and use regular SQL for running any types of queries on this data. Using the implicit type casts and post-parse `ANALYZE` hook, the `vops` extension either transforms the query to use vector operators for filtering and aggregation, or processes the data using scalar operators for other query types. For details, see [Section F.68.5.3](#).

## F.68.5. Usage

### F.68.5.1. Converting Data into Vectorized Format

To start using vector operations, you have to convert your data into a vectorized format, as explained below.

#### 1. Create an empty vectorized table.

To use vector operations, you need to load data into a tile-based vectorized table, which can be treated as a *projection* of the original table. It can map all columns of the original table, or include some of the most frequently used columns only. To create a vectorized table, you can use the regular [CREATE TABLE](#) syntax, but at least some of the columns must be of [vector types](#).

For example, suppose you have the following table from the TPC-H benchmark:

```
CREATE TABLE lineitem(  
    l_orderkey integer,  
    l_partkey integer,  
    l_suppkey integer,  
    l_linenumber integer,  
    l_quantity double precision,  
    l_extendedprice double precision,  
    l_discount double precision,  
    l_tax double precision,  
    l_returnflag "char",
```

```
l_linestatus "char",
l_shipdate date,
l_commitdate date,
l_receiptdate date,
l_shipinstruct char(25),
l_shipmode char(10),
l_comment char(44));
```

To create a vectorized projection that includes only a subset of the original columns, you can run:

```
CREATE TABLE vops_lineitem(
  l_shipdate vops_date not null,
  l_quantity vops_float8 not null,
  l_extendedprice vops_float8 not null,
  l_discount vops_float8 not null,
  l_tax vops_float8 not null,
  l_returnflag vops_char not null,
  l_linestatus vops_char not null
);
```

Alternatively, you can keep the scalar type for some of the columns. In this case, you can sort the data by these columns when loading the data. For example, let's create another vectorized projection where `l_returnflag` and `l_linestatus` fields remain scalar:

```
CREATE TABLE vops_lineitem_projection(
  l_shipdate vops_date not null,
  l_quantity vops_float8 not null,
  l_extendedprice vops_float8 not null,
  l_discount vops_float8 not null,
  l_tax vops_float8 not null,
  l_returnflag "char" not null,
  l_linestatus "char" not null
);
```

In this table, `l_returnflag` and `l_linestatus` fields are scalar, while all the other fields are of the vector types that can be used in vector operations.

## 2. Load the data into the vectorized table.

- If the data to load is already stored in your database, use the [populate\(\)](#) function to preprocess the data and unite attribute values of several rows inside a single tile. This function loads the data from the original table into its vectorized projection, using vector types instead of scalar types, as specified in the created empty table.

For example:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=
  'lineitem'::regclass);
```

Once the table is populated, you can start running queries performing sequential scan.

Optionally, you can sort the data by one or more scalar columns when loading the data:

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
  'lineitem'::regclass, sort := 'l_returnflag,l_linestatus');
```

If you sort the original table by the scalar columns that have a lot of duplicates, `vops` can effectively collapse them and store the corresponding attribute values in tiles, which can reduce the occupied space, speed up queries, and facilitate [index creation](#) on these scalar columns.

- If your data is not yet loaded into the database and you would like to avoid having two copies of the same dataset, you can import the data into a vectorized table directly from a CSV file using the [import\(\)](#) function, bypassing creation of a regular table. For example:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/
lineitem.csv', separator := '|');
```

For detailed description and syntax of the `populate()` and `import()` functions, see [Section F.68.6.4](#).

Once your data is in the tile-based format, you can run queries on this data using [vector operators](#), as described in [Section F.68.5.2](#). If you create a foreign vectorized table, you can also run regular SQL queries. See [Section F.68.5.3](#) for details.

## F.68.5.2. Running Queries on Vectorized Data

`vops` implements its own vector functions and operators for working with vectorized data. See [Section F.68.6](#) for the full list of vector functions and operators and their usage specifics.

### F.68.5.2.1. Aggregating Vectorized Data

OLAP queries often aggregate large volumes of data. To enable aggregate operations for vector types, `vops` implements the following aggregate functions for vectorized data: `count`, `min`, `max`, `avg`, `var_pop`, `var_sampl`, `variance`, `stddev_pop`, `stddev_samp`, `stddev`. Besides, `vops` provides the `wavg` aggregate function that calculates volume-weighted average price (VWAP).

The `vops` extension supports the following types of aggregates:

- grand aggregates calculated for the whole table
- aggregates for subsets of table rows defined by the `GROUP BY` clause

#### F.68.5.2.1.1. Calculating Grand Aggregates

To calculate grand aggregates, you can use the provided vector aggregate functions exactly like in regular SQL queries.

##### Examples:

To calculate volume-weighted average price, run the following query:

```
SELECT wavg(l_extendedprice, l_quantity) FROM vops_lineitem;
```

To calculate the company revenue for the year 1996 based on discounted prices of the shipped goods, run:

```
SELECT sum(l_extendedprice*l_discount) AS revenue
FROM vops_lineitem
WHERE filter(betwixt(l_shipdate, '1996-01-01', '1997-01-01')
& betwixt(l_discount, 0.08, 0.1)
& (l_quantity < 24));
```

#### F.68.5.2.1.2. Calculating Grouped Aggregates

To support grouped aggregates, `vops` provides `map()` and `reduce()` functions:

- The `map()` function collects aggregate states for all groups in a hash table. Its syntax is as follows:

```
map(group_by_expression,
    aggregate_list, expr {,
    expr })
```

- The `reduce()` function iterates through the hash table constructed by `map` and returns the set. The `reduce` function is needed because the result of aggregation in Postgres Pro cannot be a set.

Consider the following example:

```
SELECT reduce(map(l_returnflag||l_linestatus, 'sum,sum,sum,sum,avg,avg,avg',
    l_quantity,
    l_extendedprice,
    l_extendedprice*(1-l_discount),
```

```
l_extendedprice*(1-l_discount)*(1+l_tax),
l_quantity,
l_extendedprice,
l_discount))
FROM vops_lineitem
WHERE filter(l_shipdate <= '1998-12-01'::date);
```

The concatenation operator `||` performs grouping by two columns. The `vops` extension supports grouping only by an integer type. The `map` function accepts aggregation arguments as a variadic array, so all elements of this array should have the same type. For example, you cannot calculate aggregates for `vops_float4` and `vops_int8` columns in a single operation.

An aggregate string in `map` function should contain the list of aggregate functions to call, in a comma-separated format. Standard lowercase names should be used: `count`, `sum`, `agg`, `min`, `max`. `Count` is executed for the particular column: `count(x)`. There is no need to explicitly specify `count(*)` because the number of records in each group is returned by `reduce` function in any case.

`reduce` function returns set of the `vops_aggregate` type. It contains three components: the value of the `GROUP BY` expression, the number of records in the group, and an array of floats with aggregate values. The values of all aggregates, including `count` and `min/max`, are returned as floats.

Alternatively, you can partition the vectorized table by the `GROUP BY` fields to calculate grouped aggregates. In this case, grouping keys are stored as regular scalar values, while other fields are stored inside tiles. Now Postgres Pro executor will execute `vops` aggregates for each group:

```
SELECT
    l_returnflag,
    l_linestatus,
    sum(l_quantity) as sum_qty,
    sum(l_extendedprice) AS sum_base_price,
    sum(l_extendedprice*(1-l_discount)) AS sum_disc_price,
    sum(l_extendedprice*(1-l_discount)*(1+l_tax)) AS sum_charge,
    avg(l_quantity) AS avg_qty,
    avg(l_extendedprice) AS avg_price,
    avg(l_discount) AS avg_disc,
    count(*) AS count_order
FROM
    vops_lineitem_projection
WHERE
    filter(l_shipdate <= '1998-12-01'::date)
GROUP BY
    l_returnflag,
    l_linestatus
ORDER BY
    l_returnflag,
    l_linestatus;
```

In this example, `l_returnflag` and `l_linestatus` fields of the `vops_lineitem_projection` table have the `char` type, while all the other used fields are of vector types. The query above is executed even faster than query with the `map()` and `reduce()` functions. The main problem with this approach is that you have to create a separate projection for each combination of the `GROUP BY` keys to be used in queries.

#### F.68.5.2.2. Using Vector Window Functions

The `vops` extension provides limited support for Postgres Pro window functions. It provides `mcount`, `msum`, `mmin`, `mmax`, `mavg`, and `lag` functions that correspond to the standard Postgres Pro window functions `count`, `sum`, `min`, `max`, `avg`, and `lag` functions, respectively.

Note the following important restrictions:

1. Filtering, grouping, and sorting can be done only by scalar attributes.

2. Vector window functions only support window frames specified with `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

### Examples:

```
SELECT vops_unnest(t.*)
FROM (SELECT mcount(*) over w,mcount(x) over w,msum(x) over w,mavg(x) over w,mmin(x)
over w,mmax(x) over w,x - lag(x) over w
FROM v window w
AS (rows between unbounded preceding and current row)) t;
```

#### F.68.5.2.3. Converting Results to Horizontal Format

A query from the `vops` projection returns a set of tiles. The output function of a tile type can print the tile contents. However, if you want to convert the result to the horizontal format where each tuple represents a single record, use the `vops-unnest` function. For example:

```
SELECT vops_unnest(l.*)
FROM vops_lineitem l
WHERE filter(l_shipdate >= '1998-12-01'::date);
```

#### F.68.5.3. Using Standard SQL for Vector Operations

Vector operators can efficiently execute only filtering and aggregation queries. For other query types, you have to run regular SQL queries. The `vops` extension offers the following options:

- Use the original table, if any.
- Enable a foreign data wrapper (FDW) using `postgres_fdw` to present a vectorized table to Postgres Pro as a regular table with scalar column types.

If you use `postgres_fdw` with the `vops` extension, vectorized data is not really foreign: it is stored inside the database in an alternative vectorized format. FDW allows to hide specifics of the vectorized format and provides the following opportunities for working with vectorized data:

1. Extract the data from a vectorized table and present it in the horizontal format, so that it can be processed by upper nodes in the query execution plan.
2. Push filtering and aggregation queries down to vector operations.
3. Get statistic for the underlying table by running `ANALYZE` for the foreign table. The collected statistic can be used by the query optimizer, so query execution plan should be almost the same as for regular tables.

Thus, by placing a vectorized projection under FDW, you can use standard SQL without any `vops`-specific functions to perform sequential scan and aggregation queries as if they are explicitly written for the `vops` table, and execute any other queries on this data at the same time, including `JOIN` operations, common table expressions (CTE), etc. The queries that can be efficiently executed by vector operations will be pushed by Postgres Pro query optimizer to `vops` FDW and will be executed using vector operators. For other queries, the data is fetched from vectorized tables as standard tuples. If it is determined that vector operations are required, `vops` uses a post-parse `ANALYZE` hook that replaces scalar boolean operations with vector boolean operations:

| Original Expression                    | Transformed Expression                     |
|----------------------------------------|--------------------------------------------|
| <code>NOT filter(o1)</code>            | <code>filter(vops_bool_not(o1))</code>     |
| <code>filter(o1) AND filter(o2)</code> | <code>filter(vops_bool_and(o1, o2))</code> |
| <code>filter(o1) OR filter(o2)</code>  | <code>filter(vops_bool_or(o1, o2))</code>  |

There is only one difference between standard SQL and its vectorized extension. You still have to perform explicit type cast for string literals. For example, `l_shipdate <= '1998-12-01'` will not work for the `l_shipdate` column with vector type. Postgres Pro Enterprise has two overloaded versions of the `<=` operator to choose the appropriate scalar or vector type:

- `vops_date <= vops_date`

- vops\_date <= date

The example below shows creation of a vectorized table via postgres\_fdw and some queries on it:

```
CREATE FOREIGN TABLE lineitem_fdw (
    l_suppkey int4 not null,
    l_orderkey int4 not null,
    l_partkey int4 not null,
    l_shipdate date not null,
    l_quantity float8 not null,
    l_extendedprice float8 not null,
    l_discount float8 not null,
    l_tax float8 not null,
    l_returnflag "char" not null,
    l_linestatus "char" not null
) SERVER vops_server OPTIONS (table_name 'vops_lineitem');
```

```
EXPLAIN SELECT
    sum(l_extendedprice*l_discount) AS revenue
FROM
    lineitem_fdw
WHERE
    l_shipdate BETWEEN '1996-01-01' AND '1997-01-01'
    AND l_discount BETWEEN 0.08 AND 0.1
    AND l_quantity < 24;
```

QUERY PLAN

```
-----
Foreign Scan  (cost=1903.26..1664020.23 rows=1 width=4)
(1 row)
```

-- Filter was pushed down to FDW

```
EXPLAIN SELECT
    n_name,
    count(*),
    sum(l_extendedprice * (1-l_discount)) AS revenue
FROM
    customer_fdw JOIN orders_fdw ON c_custkey = o_custkey
    JOIN lineitem_fdw ON l_orderkey = o_orderkey
    JOIN supplier_fdw ON l_suppkey = s_suppkey
    JOIN nation ON c_nationkey = n_nationkey
    JOIN region ON n_regionkey = r_regionkey
WHERE
    c_nationkey = s_nationkey
    AND r_name = 'ASIA'
    AND o_orderdate >= '1996-01-01'
    AND o_orderdate < '1997-01-01'
GROUP BY
    n_name
ORDER BY
    revenue desc;
```

QUERY PLAN

```
-----
Sort  (cost=2337312.28..2337312.78 rows=200 width=48)

                    -> Hash Join (cost=40.97..2790.80 rows=7702
width=44)
                        Hash Cond: (supplier_fdw.s_nationkey =
nation.n_nationkey)
                        -> Foreign Scan on supplier_fdw
(cost=0.00..2174.64 rows=100032 width=8)
                        -> Hash (cost=40.79..40.79 rows=15
width=36)
                            -> Hash Join (cost=20.05..40.79
rows=15 width=36)
                                Hash Cond: (nation.n_regionkey
= region.r_regionkey)
                                -> Seq Scan on nation
(cost=0.00..17.70 rows=770 width=40)
                                -> Hash (cost=20.00..20.00
rows=4 width=4)
                                    -> Seq Scan on region
(cost=0.00..20.00 rows=4 width=4)
                                        Filter:
((r_name)::text = 'ASIA'::text)
                                        -> Hash (cost=294718.76..294718.76 rows=2284376 width=8)
                                            -> Foreign Scan on orders_fdw (cost=0.00..294718.76
rows=2284376 width=8)
                                            -> Hash (cost=32605.64..32605.64 rows=1500032 width=8)
                                                -> Foreign Scan on customer_fdw (cost=0.00..32605.64
rows=1500032 width=8)

-- filter on orders range is pushed to FDW

```

#### F.68.5.4. Building Indexes for Vectorized Tables

Analytic queries are usually performed on the data for which no indexes are defined. Vector operations on tiles are most effective in this case. However, you can still use indexes with vectorized data.

Since each tile represents multiple values, an index can be used only for some preliminary, non-precise filtering of data. The `vops` extension provides the following pairs of functions to obtain boundary values stored in the tile:

- `first()` and `last()` functions should be used for sorted dataset. In this case, the first and the last values in the tile are the smallest and the largest values in the tile, respectively.
- `high()` and `low()` functions should be used for unsorted data. These functions are more expensive because they need to inspect all tile values.

Using the returned values, you can construct functional indexes for vectorized data. The BRIN index seems to be the best choice:

```
CREATE INDEX low_boundary ON trades
USING brin(first(day)); -- trades table is ordered by day
CREATE INDEX high_boundary ON trades
USING brin(last(day)); -- trades table is ordered by day
```

Now you can use the created indexes in queries. However, you have to recheck the precise condition because such an index only gives an approximate result:

```
SELECT sum(price) FROM trades
WHERE first(day) >= '2015-01-01' AND last(day) <= '2016-01-01'
AND filter(betwixt(day, '2015-01-01', '2016-01-01'));
```

### F.68.5.5. Automating Projection Usage

`vops` can automate most of the operations required to create and maintain vectorized data projections. In this case, you do not have to use [postgres\\_fdw](#): `vops` can redirect regular SQL queries to projection tables automatically. However, these queries must satisfy the following criteria to get redirected:

- The query does not contain joins.
- The query performs aggregation of vector columns.
- All other expressions in the target list, as well as `ORDER BY` and `GROUP BY` clauses refer only to scalar columns.

To enable automatic query redirection to a vectorized projection of your data, do the following:

#### 1. Create a vectorized projection of the table using the `create_projection()` function.

For example, to create a projection for the `lineitem` table shown above, similar to the `vops_lineitem`, run:

```
SELECT create_projection('auto_vops_lineitem', 'lineitem',
    array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
    array['l_returnflag', 'l_linestatus']);
```

In this example, the first two arguments specify the projection table and the original table, respectively, the first array defines all the vector columns to be included into the projection, and the second array specifies the scalar columns that will be used for grouping vectorized data into tiles.

Additionally, you can provide an optional `order_by` parameter to speed up subsequent projection refresh operations. The `order_by` values should be unique. For example, to sort all table entries by `l_shipdate`, you can create a projection table as follows:

```
SELECT create_projection('auto_vops_lineitem_ordered', 'lineitem',
    array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
    array['l_returnflag', 'l_linestatus'],
    'l_shipdate');
```

#### 2. Set the `vops.auto_substitute_projections` parameter to `on`.

Now all queries that `vops` can redirect to the `auto_vops_lineitem` projection table will be run on the vectorized data.

Projections are not updated automatically, so once the original table gets updated, implicitly redirected queries can start returning inaccurate results. To avoid this, you have to refresh the projections before running queries on the vectorized data. For this purpose, `vops` provides the `pname_refresh()` functions, where the `pname` prefix is the name of the projection you need to refresh. For example, to refresh the `auto_vops_lineitem` projection, run:

```
SELECT auto_vops_lineitem_refresh();
```

This function calls the `populate()` method to update all the fields present in the projection. If you have specified the optional `order_by` parameter when creating the projection, only the new data will be im-

ported from the original table, selecting only the rows with the `order_by` column value greater than the maximal value of this column in the projection. Otherwise, the whole table will be re-written. The `populate()` method also takes the grouping columns into account to efficiently group the imported data in tiles.

If you have specified the `order_by` attribute when creating a projection, `vops` also creates the following indexes:

- Two functional BRIN indexes on `first()` and `last()` functions of this attribute. Such indexes allow to efficiently select time slices. For example, if the original query contains predicates like `(l_shipdate between '01-01-2017' and '01-01-2018')`, `vops` adds the `(first(l_shipdate) >= '01-01-2017' and last(l_shipdate) >= '01-01-2018')` conjuncts when redirecting the query, so that Postgres Pro optimizer can quickly locate the affected pages using BRIN indexes.
- A BRIN index for scalar columns used for grouping. Such index allows to efficiently select groups and perform index joins.

## F.68.6. Reference

### F.68.6.1. Vector Types

The `vops` extension supports all basic Postgres Pro numeric types: 1-, 2-, 4-, 8-byte integers, as well as 4- and 8-byte floats. The `date` and `timestamp` types are using the same implementation as `int4` and `int8`, respectively. The table below illustrates the available vector types, as compared to the corresponding SQL and C types.

| SQL Type                                       | C Type                 | <code>vops</code> Vector Type |
|------------------------------------------------|------------------------|-------------------------------|
| <code>bool</code>                              | <code>bool</code>      | <code>vops_bool</code>        |
| <code>"char"</code>                            | <code>char</code>      | <code>vops_char</code>        |
| <code>date</code>                              | <code>DateADT</code>   | <code>vops_date</code>        |
| <code>int2</code>                              | <code>int16</code>     | <code>vops_int2</code>        |
| <code>int4</code>                              | <code>int32</code>     | <code>vops_int4</code>        |
| <code>int8</code>                              | <code>int64</code>     | <code>vops_int8</code>        |
| <code>float4</code>                            | <code>float4</code>    | <code>vops_float4</code>      |
| <code>float8</code>                            | <code>float8</code>    | <code>vops_float8</code>      |
| <code>timestamp</code>                         | <code>Timestamp</code> | <code>vops_timestamp</code>   |
| <code>char(N)</code> , <code>varchar(N)</code> | <code>text</code>      | <code>vops_text(N)</code>     |

### Note

For performance reasons, using `vops_text` for single-character strings is not recommended. If you are using strings as identifiers, you can place them in a dictionary and use integer identifiers instead of the original strings.

### F.68.6.2. Vector Operators

The `vops` extension provides a set of operators for vector types.

#### F.68.6.2.1. Mathematical Operators

For mathematical operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

| Operator       | Description |
|----------------|-------------|
| <code>+</code> | Addition    |

| Operator | Description                                                                                                                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| –        | Binary subtraction or unary negation                                                                                                                                                                                                                                                                    |
| *        | Multiplication                                                                                                                                                                                                                                                                                          |
| /        | Division                                                                                                                                                                                                                                                                                                |
|          | Concatenation. This operator is only supported for <code>char</code> , <code>int2</code> , and <code>int4</code> types. It returns an integer type of a doubled size:<br><br><code>(char    char) -&gt; int2</code><br><code>(int2    int2) -&gt; int4</code><br><code>(int4    int4) -&gt; int8</code> |

#### F.68.6.2.2. Comparison Operators

For comparison operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

| Operator | Description            |
|----------|------------------------|
| =        | Equals                 |
| <>       | Not equals             |
| <        | Less than              |
| <=       | Less than or equals    |
| >        | Greater than           |
| >=       | Greater than or equals |

#### F.68.6.2.3. Boolean Operators

Boolean operators `AND`, `OR`, and `NOT` cannot be overloaded, so `vops` provides its own implementation of boolean operators for vector types:

| Operator | Description |
|----------|-------------|
| &        | Boolean AND |
|          | Boolean OR  |
| !        | Boolean NOT |

Vector boolean operators have the following usage specifics:

- The precedence of vector boolean operators is different from `AND`, `OR`, and `NOT`, so you have to enclose the operands into parentheses. For example:  
`(x=1) | (x=2)`
- The result of vector boolean operations is `vops_bool`. Since Postgres Pro requires predicate expressions to have a regular boolean type, you have to convert the result to the `bool` type using the `filter()` function. Taking a vector boolean expression, this function calculates a `filter_mask` value that defines the result of this boolean operation for each vector element. If all mask bits are zero (the predicate is false for all vector elements), then `filter()` returns `false`, and Postgres Pro executor skips this record. Otherwise, `true` is returned, so vector operators will check the `filter_mask` value for the selected vector elements in subsequent operations.
- When using vector boolean operators, you have to use explicit cast of string constants to the required data type.

#### F.68.6.3. Comparison Functions

| Function                           | Description                                                |
|------------------------------------|------------------------------------------------------------|
| <code>bitwixt(x, low, high)</code> | Same as the <code>x BETWEEN low AND high</code> predicate. |

| Function                      | Description                                          |
|-------------------------------|------------------------------------------------------|
| <code>is_null(x)</code>       | Same as the <i>expression</i> IS NULL predicate.     |
| <code>is_not_null(x)</code>   | Same as the <i>expression</i> IS NOT NULL predicate. |
| <code>ifnull(x, subst)</code> | Same as the COALESCE function.                       |

#### F.68.6.4. Conversion Functions

```
create_projection(projection_name text, source_table regclass, vector_columns text[],
scalar_columns text[] DEFAULT null, order_by text DEFAULT null)
```

Creates a projection table with specified name and attributes and updates the `vops_projections` table to include the information about this projection, so that the optimizer can automatically redirect queries from the original table to its projection. It also creates the `pname_refresh()` function that can update the projection.

Arguments:

- *projection\_name* — the name of the projection table.
- *source\_table* — the original Postgres Pro table for which to create a vectorized projection.
- *vector\_columns* — an array of column names that will be stored as `vops` tiles.
- *scalar\_columns* — an array of column names that will preserve its original scalar type. These columns will be used to group table rows into `vops` tiles. `vops` automatically builds a BRIN index over such columns.
- *order\_by* — an optional vector column that can be used to sort data in the projection table. Sorting can be useful to incrementally update the projection after the original table updates using the `pname_refresh()` function. This column should contain unique timestamp values, such as trade dates. `vops` automatically builds a functional BRIN index for `first()` and `last()` functions of this column.

Examples:

```
SELECT
  create_projection('vops_lineitem', 'lineitem', array['l_shipdate', 'l_quantity', 'l_extended
pname_refresh()
```

Refreshes the *pname* projection table.

Examples:

Refresh the `vops_lineitem` projection:

```
SELECT vops_lineitem_refresh();
drop_projection(projection_name text)
```

Drops the specified projection and the corresponding refresh function, as well as removes the information about this projection from the `vops_projections` table.

Examples:

Drop the `vops_lineitem` projection:

```
SELECT drop_projection(vops_lineitem);
populate(destination regclass, source regclass, predicate cstring DEFAULT null, sort
cstring DEFAULT null)
```

Copies the data from an existing table to its vectorized projection and returns the number of imported rows (`bigint`).

**Arguments:**

- *destination* — target table to copy the data into.

Type: regclass

- *source* — source table to copy the data from.

Type: regclass

- *predicate* — restricts the amount of imported data (optional). Using this argument, you can upload only the most recent records.

Type: cstring

- *sort* — sorts the source data to define the order in which the data needs to be loaded (optional).

Type: cstring

**Examples:**

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=  
  'lineitem'::regclass);
```

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=  
  'lineitem_projection'::regclass, sort := 'l_returnflag,l_linestatus');
```

```
import(destination regclass, csv_path cstring, separator cstring DEFAULT ',', skip integer  
DEFAULT 0)
```

Loads the data into a `vops` table directly from a CSV file, bypassing creation of a regular table, and returns the number of imported rows (`bigint`). Use this function to avoid storing two copies of the same dataset.

**Arguments:**

- *destination* — target table to copy the data into.

Type: regclass

- *csv\_path* — the path to the CSV file to copy the data from.

Type: cstring

- *separator* — specifies the field separator used in the CSV file (optional). By default, the comma is assumed to be the field separator.

Type: cstring

- *skip* — specifies the number of rows in the CSV header that do not need to be imported (optional).

Default: 0

Type: cstring

**Examples:**

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/  
lineitem.csv', separator := '|');
```

```
vops_unnest(anyelement)
```

Scatters records with `vops` types into records with scalar types.

### F.68.6.5. Configuration Parameters

`vops.auto_substitute_projections` (boolean)

Enables automatic query redirection to projection tables. For correct results, you have to ensure that the projection is synchronized with the original table.

Default: `off`

### F.68.7. Authors

Postgres Professional, Moscow, Russia

## F.69. xml2

The `xml2` module provides XPath querying and XSLT functionality.

### F.69.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to [<pgsql-hackers@lists.postgresql.org>](mailto:pgsql-hackers@lists.postgresql.org) so that the deficiency can be addressed.

### F.69.2. Description of Functions

[Table F.49](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries. All arguments are of type `text`, so for brevity that is not shown.

**Table F.49. Functions**

| Function                                                      | Returns             | Description                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>xml_valid(document)</code>                              | <code>bool</code>   | This parses the document text in its parameter and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.) |
| <code>xpath_string(document, query)</code>                    | <code>text</code>   | These functions evaluate the XPath query on the supplied document, and cast the result to the specified type.                                                                                                                                                                                                                         |
| <code>xpath_number(document, query)</code>                    | <code>float4</code> |                                                                                                                                                                                                                                                                                                                                       |
| <code>xpath_bool(document, query)</code>                      | <code>bool</code>   |                                                                                                                                                                                                                                                                                                                                       |
| <code>xpath_node_set(document, query, toptag, itemtag)</code> | <code>text</code>   | This evaluates query on document and wraps the result in XML tags. If the result is multivalued, the output will look like:<br><br><pre>&lt;toptag&gt; &lt;itemtag&gt;Value 1 which   could be an XML fragment&lt;/ itemtag&gt;</pre>                                                                                                 |

| Function                                               | Returns | Description                                                                                                                                                                                    |
|--------------------------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                        |         | <pre>&lt;itemtag&gt;Value 2....&lt;/itemtag&gt;</pre> <pre>&lt;/toptag&gt;</pre> <p>If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.</p> |
| <code>xpath_node_set (document, query)</code>          | text    | Like <code>xpath_node_set (document, query, toptag, itemtag)</code> but result omits both tags.                                                                                                |
| <code>xpath_node_set (document, query, itemtag)</code> | text    | Like <code>xpath_node_set (document, query, toptag, itemtag)</code> but result omits <code>toptag</code> .                                                                                     |
| <code>xpath_list (document, query, separator)</code>   | text    | This function returns multiple values separated by the specified separator, for example Value 1, Value 2, Value 3 if separator is , .                                                          |
| <code>xpath_list (document, query)</code>              | text    | This is a wrapper for the above function that uses , as the separator.                                                                                                                         |

### F.69.3. xpath\_table

`xpath_table(text key, text document, text relation, text xpaths, text criteria)` returns setof record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.50](#).

**Table F.50. xpath\_table Parameters**

| Parameter       | Description                                                                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>key</i>      | the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values) |
| <i>document</i> | the name of the field containing the XML document                                                                                                                                                            |
| <i>relation</i> | the name of the table or view containing the documents                                                                                                                                                       |
| <i>xpaths</i>   | one or more XPath expressions, separated by                                                                                                                                                                  |
| <i>criteria</i> | the contents of the WHERE clause. This cannot be omitted, so use <code>true</code> or <code>1=1</code> if you want to process all the rows in the relation                                                   |

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or docu-

ment). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a `FROM` expression, with an `AS` clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be `NULL`.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|/article/author/@id',
                'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
    AS t(article_id integer, title text, author_id integer),
    tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

### F.69.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');
```

```

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
  xpath_table('id','xml','test',
              '/doc/@num|/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num

```

| id | doc_num | line_num | val1 | val2 | val3 |
|----|---------|----------|------|------|------|
| 1  | C1      | L1       | 1    | 2    | 3    |
| 1  |         | L2       | 11   | 22   | 33   |

To get doc\_num on every line, the solution is to use two invocations of `xpath_table` and join the results:

```

SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;

```

| id | line_num | val1 | val2 | val3 | doc_num |
|----|----------|------|------|------|---------|
| 1  | L1       | 1    | 2    | 3    | C1      |
| 1  | L2       | 11   | 22   | 33   | C1      |

(2 rows)

## F.69.4. XSLT Functions

The following functions are available if `libxslt` is installed:

### F.69.4.1. `xslt_process`

`xslt_process(text document, text stylesheet, text paramlist)` returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

## F.69.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. ([www.torchbox.com](http://www.torchbox.com)). It has the same BSD license as Postgres Pro.

---

# Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding additional modules available in the Postgres Pro Enterprise distribution. See [Appendix F](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Enterprise installation and can be used like any other program.

## G.1. Client Applications

This section covers Postgres Pro Enterprise client applications. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications that are part of the core Postgres Pro Enterprise distribution.

## oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

## Synopsis

```
oid2name [option...]
```

## Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 68](#).

### Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

## Options

oid2name accepts the following command-line arguments:

`-f filenode`

show info for table with filenode *filenode*

`-i`

include indexes and sequences in the listing

`-o oid`

show info for table with OID *oid*

`-q`

omit headers (useful for scripting)

`-s`

show tablespace OIDs

`-S`

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas)

`-t tablename_pattern`

show info for table(s) matching *tablename\_pattern*

`-V`

`--version`

Print the oid2name version and exit.

`-x`

display more information about each object shown: tablespace name, schema name, and OID

-?  
--help

Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

-d *database*

database to connect to

-H *host*

database server's host

-p *port*

database server's port

-U *username*

user name to connect as

-P *password*

password (deprecated — putting this on the command line is a security hazard)

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-s` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

## Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

## Examples

```
$ # what's in this database server, anyway?
```

```
$ oid2name
```

```
All databases:
```

| Oid   | Database Name | Tablespace |
|-------|---------------|------------|
| 17228 | alvherre      | pg_default |
| 17255 | regression    | pg_default |
| 17227 | template0     | pg_default |
| 1     | template1     | pg_default |

```
$ oid2name -s
```

```
All tablespaces:
```

| Oid    | Tablespace Name |
|--------|-----------------|
| 1663   | pg_default      |
| 1664   | pg_global       |
| 155151 | fastdisk        |
| 155152 | bigdisk         |

```
$ # OK, let's look into database alvherre
```

```
$ cd $PGDATA/base/17228
```

```
$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
```

```
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173
-rw----- 1 alvherre alvherre 17965056 sep 14 09:51 1155291
-rw----- 1 alvherre alvherre 1204224 sep 14 09:51 16717
-rw----- 1 alvherre alvherre 581632 sep 6 17:51 1255
-rw----- 1 alvherre alvherre 237568 sep 14 09:50 16674
-rw----- 1 alvherre alvherre 212992 sep 14 09:51 1249
-rw----- 1 alvherre alvherre 204800 sep 14 09:51 16684
-rw----- 1 alvherre alvherre 196608 sep 14 09:50 16700

-rw----- 1 alvherre alvherre 122880 sep 6 17:51 16751
```

```
$ # I wonder what file 155173 is ...
```

```
$ oid2name -d alvherre -f 155173
```

```
From database "alvherre":
```

```
Filenode Table Name
-----
155173 accounts
```

```
$ # you can ask for more than one object
```

```
$ oid2name -d alvherre -f 155173 -f 1155291
```

```
From database "alvherre":
```

```
Filenode Table Name
-----
155173 accounts
1155291 accounts_pkey
```

```
$ # you can mix the options, and get more details with -x
```

```
$ oid2name -d alvherre -t accounts -f 1155291 -x
```

```
From database "alvherre":
```

```
Filenode Table Name Oid Schema Tablespace
-----
155173 accounts 155173 public pg_default
1155291 accounts_pkey 1155291 public pg_default
```

```
$ # show disk space for every db object
```

```
$ du [0-9]* |
```

```
> while read SIZE FILENODE
```

```
> do
```

```
> echo "$SIZE `oid2name -q -d alvherre -i -f $FILENODE`"
```

```
> done
```

```
16 1155287 branches_pkey
16 1155289 tellers_pkey
17561 1155291 accounts_pkey
...
```

```
$ # same, but sort by size
```

```
$ du [0-9]* | sort -rn | while read SIZE FN
```

```
> do
```

```
> echo "$SIZE `oid2name -q -d alvherre -f $FN`"
```

```
> done
```

```
133466 155173 accounts
17561 1155291 accounts_pkey
1177 16717 pg_proc_proname_args_nsp_index
...
```

```
$ # If you want to see what's in tablespaces, use the pg_tblspc directory
$ cd $PGDATA/pg_tblspc
$ oid2name -s
All tablespaces:
  Oid   Tablespace Name
-----
  1663      pg_default
  1664      pg_global
 155151      fastdisk
 155152      bigdisk

$ # what databases have objects in tablespace "fastdisk"?
$ ls -d 155151/*
155151/17228/ 155151/PG_VERSION

$ # Oh, what was database 17228 again?
$ oid2name
All databases:
  Oid   Database Name   Tablespace
-----
 17228      alvherre   pg_default
 17255      regression pg_default
 17227      template0  pg_default
    1      template1  pg_default

$ # Let's see what objects does this database have in the tablespace.
$ cd 155151/17228
$ ls -l
total 0
-rw-----  1 postgres postgres 0 sep 13 23:20 155156

$ # OK, this is a pretty small table ... but which one is it?
$ oid2name -d alvherre -f 155156
From database "alvherre":
  Filenode   Table Name
-----
  155156      foo
```

### Author

## pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

### Synopsis

```
pgbadger [connection-option...] [option...] [logfile...]
```

### Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

*logfile* can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass “-” as *logfile*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the `log_line_prefix` configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

[pgbouncer](#) log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at <https://pgbadger.darold.net/#reports>.

### Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

### Setup and Configuring

Once you have pgbadger installed, complete the setup described in sections below.

#### [Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

#### [Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

```
sudo yum install perl-JSON-XS
```

### [Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- `zcat` for `gz`
- `bzcat` for `bz2`
- `lz4cat` for `lz4`
- `zstdcat` for `zst`
- `unzip` or `xz` for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"  
--zcat="C:\tools\unzip -p"
```

### Note

With the default autodetection of the compressed file format, you can mix `gz`, `bz2`, `lz4`, `xz`, `zip` and `zstd` log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

## Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

To enable SQL query logging and have the query statistics include actual query strings, set

```
log_min_duration_statement = 0
```

On a busy server you may want to increase this value to only log queries with a longer duration.

If you just want to report the duration and number of queries and do not want details of queries, set `log_min_duration_statement` to `-1`, which disables logging statement durations, and enable `log_duration`.

Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set `log_statement` to `all`, the setting of `log_min_duration_statement` will have no effect.

### Warning

Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in `log_line_prefix`.

It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for `stderr` logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable [log\\_statement](#) as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

## Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-11/data/log/postgres.log.2.gz /var/lib/pgpro/ent-11/data/
log/postgres.log.1.gz /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-11/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/ent-11/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/ent-11/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/ent-11/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@d %p %r %a : ' /var/lib/pgpro/ent-11/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/ent-11/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/ent-11/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/ent-11/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

## Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/ent-11/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/ent-11/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote [pgbouncer](#) log file together:

```
pgbadger /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

## Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in pgbadger follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks pgbadger may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

| Option | 1 CPU   | 2 CPU | 4 CPU | 8 CPU |
|--------|---------|-------|-------|-------|
| -j     | 1h41m18 | 50m25 | 25m39 | 15m58 |
| -J     | 1h41m18 | 54m28 | 41m16 | 34m45 |

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

| Option | 1 CPU   | 2 CPU | 4 CPU | 8 CPU |
|--------|---------|-------|-------|-------|
| -j     | 1h41m18 | 50m25 | 25m39 | 15m58 |
| -J     | 1h41m18 | 54m28 | 41m16 | 34m45 |

```
-j      | 20m15 | 9m56 | 5m20 | 4m20  
-J      | 20m15 | 9m49 | 5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

### Important

During parallel parsing, `pgbadger` generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

## Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/ent-11/data/log/ -mtime -7 -name  
"postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +%F`.html -l /var/reports/  
pgbadger_incremental_file.dat
```

But better turn on `pgbadger`'s automatic building incremental reports by specifying the `-I/--incremental` option. In this mode, `pgbadger` builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O/--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run `pgbadger` as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/ent-11/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode `pgbadger` will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run `pgbadger` in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-x/--extra-files` command-line option to force `pgbadger` to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O/--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/ent-11/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

If `pg_dump` is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by `pg_dump` on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

## Rebuilding Reports

To update all HTML reports after fixing a `pgbadger` report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js  
rm /path/to/reports/*.css  
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E/--explode` option if the reports were built with this option.

## Building Monthly Reports

By default, in the incremental mode pgbadger only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E/--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

## Choosing the Report File Format

The pgbadger report file format is determined by the extension of the file passed to the `-o/--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a pgbadger report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
ent-11/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/ent-11/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of pgbadger output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
ent-11/data/log/postgresql-2022-01-14_000000.log
```

## Options

This section describes pgbadger command-line options.

```
-a minutes
--average minutes
```

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A minutes`

`--histo-average minutes`

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b datetime`

`--begin datetime`

Specifies the start date/time for the data to be parsed in logs.

`-c host`

`--dbclient host`

Only report on log entries for the specified client host.

`-C`

`--nocomment`

Remove `/* ... */` comments from queries.

`-d name`

`--dbname name`

Only report on log entries for the specified database.

`-D`

`--dns-resolv`

Replace client IP addresses with their DNS names.

### Warning

This can considerably slow down pgbadger.

`-e datetime`

`--end datetime`

Specifies the end date/time for the data to be parsed in logs.

`-E`

`--explode`

Build one report per each database. Global information not related to any database gets added to the postgres database report.

`-f logtype`

`--format logtype`

Specifies the log type.

Possible values: `syslog`, `syslog2`, `stderr`, `jsonlog`, `csv`, `pgbouncer`, `logplex`, `rds` and `redshift`. Use when pgbadger cannot detect the log format.

`-G`

`--nograph`

Disables graphs in HTML output.

`-h`

`--help`

Show detailed information about pbadger options and exit.

`-H path`  
`--html-outdir path`

Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by `-O/--outdir`.

`-i name`  
`--ident name`

Specifies the program name used to identify Postgres Pro messages in syslog logs.

Default: postgres.

`-I`  
`--incremental`

Use the incremental mode, where reports will be generated by days in a separate directory specified by the `-O/--outdir` option.

`-j number`  
`--jobs number`

Specifies the number of jobs to run at same time. When working with csvlog logs, pgbadger always runs as single job.

Default: 1.

`-J number`  
`--Jobs number`

Specifies the number of log files to parse in parallel. When working with csvlog logs, one log at a time is processed.

Default: 1.

`-l filename`  
`--last-parsed filename`

Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.

`-L filename`  
`--logfile-list filename`

Specifies the file containing the list of log files to parse.

`-m size`  
`--maxlength size`

Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

`-M`  
`--no-multiline`

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

`-N name`  
`--appname name`

Only report on log entries for the specified application.

`-o filename`  
`--outfile filename`

Specifies the filename for the output and determines the report file format. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of `"-"` as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,

for the respective output format.

`-O path`  
`--outdir path`

Specifies the directory where the out file must be saved.

`-p string`  
`--prefix string`

Specifies the value of your custom `log_line_prefix` string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from [the standard log\\_line\\_prefix strings](#), for example, if your prefix includes additional variables, such as client IP or application name.

`-P`  
`--no-prettify`

Disables SQL query code prettifier.

`-q`  
`--quiet`

Disables printing anything to stdout, even the progress bar.

`-Q`  
`--query-numbering`

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

`-r address`  
`--remote-host address`

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

`-R number`  
`--retention number`

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s number`  
`--sample number`

Specifies the number of query samples to store.

Default: 3.

`-S`  
`--select-only`

Only report on SELECT queries.

`-t number`

`--top number`

Specifies the number of queries to store/display.

Default: 20.

`-T string`

`--title string`

Specifies the title of the HTML report page.

`-u username`

`--dbuser username`

Only report on log entries for the specified username.

`-U username`

`--exclude-user username`

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`

`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`

`--version`

Show pgbadger version and exit.

`-w`

`--watch-mode`

Only report errors, just like *Logwatch* can do.

`-W`

`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x format`

`--extension format`

Specifies the output format. Possible values: text, html, bin, json or tsung.

Default: html.

`-X`

`--extra-files`

In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z command`

`--zcat command`

Specifies the full command to run the zcat program. Use if zcat, bzip or unzip is outside of your PATH directories.

`-Z +/-XX`

`--timezone +/-XX`

Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs.

`--pie-limit number`

Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query regex`

Specifies the regular expression such that matching queries will be excluded from the report. For example: “`^(VACUUM|COMMIT)`”. Can be used multiple times.

`--exclude-file filename`

Specifies the path to the file that contains regular expressions to use to exclude matching queries from the report, one expression per line.

`--include-query regex`

Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: “`(tbl1|tbl2)`”.

`--include-file filename`

Specifies the path to the file that contains regular expressions to use to include matching queries in the report, one expression per line.

`--disable-error`

Turns off generation of an error report.

`--disable-hourly`

Turns off generation of an hourly report.

`--disable-type`

Turns off generation of a report on queries by type, database and user.

`--disable-query`

Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`

Turns off generation of a session report.

`--disable-connection`

Turns off generation of a connection report.

`--disable-lock`

Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset name`

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator char`

Specifies the CSV field separator.

Default: “,”.

`--exclude-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .\*”. Can be used multiple times.

`--include-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .\*”. Can be used multiple times.

`--exclude-db name`

Specifies the name of the database to exclude related log entries from the report. For example: “outdated\_db”. Can be used multiple times.

`--exclude-appname name`

Specifies the name of the application to exclude related log entries from the report. For example: “pg\_dump”. Can be used multiple time.

`--exclude-line regexp`

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client address`

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl command`

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-ent-11`.

`--pid-dir path`

Specifies the path to store the PID file.

Default: /tmp.

`--pid-file filename`

Specifies the name of the PID file to manage concurrent execution of pgbadger.

**Default:** `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show **pgbouncer**-related menu in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone +/-XX`

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated.

`--prettify-json`

Prettify JSON output.

`--month-report YYYY-MM`

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report YYYY-MM-DD`

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by **auto\_explain**.

`--command cmd`

Specifies the command to run to retrieve log entries on stdin. pgbadger will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url URL`

Specifies the URL to override the URL of the graphical explain tool.

**Default:** `http://explain.depesz.com/?is\_public=0&is\_anon=0&plan=`

`--tempdir path`

Specifies the directory for temporary files.

**Default:** `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

## Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r/--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program ssh`

Specifies the path to the SSH program to use.

Default: `ssh`.

`--ssh-port port`

Specifies the SSH port for the connection.

Default: `22`.

`--ssh-user username`

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity filename`

Specifies the path to the identity file.

`--ssh-timeout seconds`

Specifies the timeout in seconds in case of the SSH connection failure.

Default: `10`.

`--ssh-option options`

Specifies the list of options to define SSH connection parameters. The following options are always used:

`-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey`

`-o PreferredAuthentications=hostbased,publickey`

```

### Description

pg\_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg\_probackup supports PostgreSQL 9.5 or higher.

- [Overview](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

### Overview

As compared to other backup solutions, pg\_probackup offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from backup by reusing valid unchanged pages available in PGDATA.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backup from standby: avoiding extra load on master by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (PGDATA), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with master.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:
  - DELTA backup. In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
  - PAGE backup. In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.
  - PTRACK backup. In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE**. Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM**. Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *stand-alone*.

## Limitations

`pg_probackup` currently has the following limitations:

- `pg_probackup` only supports PostgreSQL 9.5 and higher.
- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro 10 or lower, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the backup command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- For Postgres Pro 9.5, functions `pg_create_restore_point(text)` and `pg_switch_xlog()` can be executed only if the backup role is a superuser, so backup of a cluster with low amount of WAL traffic by a non-superuser role can take longer than the backup of the same cluster by a superuser role.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block\\_size](#) and [wal\\_block\\_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or libc/libicu versions.

## Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.
- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.

### Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where `backup_dir` is the path to the backup catalog. If the `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the `backup_dir` directory.

`pg_probackup` creates the `backup_dir` backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

## Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name
[remote_options]
```

where:

- `data_dir` is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- `instance_name` is the name of the subdirectories that will store WAL and backup files for this cluster.
- `remote_options` are optional parameters that need to be specified only if `data_dir` is located on a remote system.

`pg_probackup` creates the `instance_name` subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the `remote_options`, the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring pg\\_probackup”](#).

The user launching `pg_probackup` must have full access to `backup_dir` directory and at least read-only access to `data_dir` directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

### Note

For Postgres Pro 11 or higher, it is recommended to use the [group access](#) feature, so that backup can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

## Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server:

For Postgres Pro 9.5:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
```

```
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;  
COMMIT;
```

#### For Postgres Pro 9.6:

```
BEGIN;  
CREATE ROLE backup WITH LOGIN;  
GRANT USAGE ON SCHEMA pg_catalog TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_xlog() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_xlog_replay_location() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;  
COMMIT;
```

#### For Postgres Pro 10 or higher:

```
BEGIN;  
CREATE ROLE backup WITH LOGIN;  
GRANT USAGE ON SCHEMA pg_catalog TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;  
COMMIT;
```

In the [pg\\_hba.conf](#) file, allow connection to the database cluster on behalf of the `backup` role.

Since `pg_probackup` needs to read cluster files directly, `pg_probackup` must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run `pg_probackup` in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

### Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- Grant the `REPLICATION` privilege to the `backup` role:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the STREAM WAL mode.

### Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

## Setting up Continuous WAL Archiving

Making backups in PAGE backup mode, performing PITR and making backups with ARCHIVE WAL delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on master, `archive_mode` must be set to `on` or `always`. To perform archiving on standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --  
instance instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the ARCHIVE WAL mode, backups in the PAGE backup mode, as well as perform PITR.

You can view the current state of the WAL archive using the `show` command. For details, see [the section called “Viewing WAL Archive Information”](#).

If you are planning to make PAGE backups and/or backups with ARCHIVE WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the `archive_timeout` Postgres Pro parameter **on master**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

### Note

Instead of using the `archive-push` command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/in-`

`stance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

### Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg\\_receivewal](#) utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

## Setting up Backup from Standby

For Postgres Pro 9.6 or higher, `pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the [hot\\_standby](#) parameter to `on`.
- On the master server, set the [full\\_page\\_writes](#) parameter to `on`.
- To perform standalone backups on standby, complete all steps in section [Setting up STREAM Backups](#).
- To perform archive backups on standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backup from the standby server has the following limitations:

- If the standby is promoted to the master during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the master, and not to use tools like `pg_compresslog` as [archive\\_command](#) to remove full-page writes from WAL files.

## Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck\\_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

## Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

## Configuring the Remote Mode

pg\_probackup supports the remote mode that allows to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

### Set up SSH

If you are going to use pg\_probackup in remote mode via SSH, complete the following steps:

- Install pg\_probackup on both systems: `backup_host` and `db_host`.
- For communication between the hosts set up the passwordless SSH connection between `backup` user on `backup_host` and `postgres` user on `db_host`:

```
[backup@backup_host] ssh-copy-id postgres@db_host
```

- If you are going to rely on [continuous WAL archiving](#), set up passwordless SSH connection between `postgres` user on `db_host` and `backup` user on `backup_host`:

```
[postgres@db_host] ssh-copy-id backup@backup_host
```

where:

- `backup_host` is the system with *backup catalog*.
- `db_host` is the system with Postgres Pro cluster.
- `backup` is the OS user on `backup_host` used to run pg\_probackup.
- `postgres` is the OS user on `db_host` used to start the Postgres Pro cluster. For Postgres Pro 11 or higher a more secure approach can be used thanks to [group access](#) feature.

pg\_probackup in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires pg\_probackup binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main pg\_probackup process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.
- The main pg\_probackup process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `db_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `db_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main pg\_probackup process, which exits with an error.
- Compression is always done on `db_host`, while decompression is always done on `backup_host`.

### Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

## Setting up PTRACK Backups

### Note

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps. The role that will perform PTRACK backups (the `backup` role in the examples below) must have access to all the databases of the cluster.

For Postgres Pro 11 or higher:

1. Create PTRACK extension:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to  $N / 1024$ , where  $N$  is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

### Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

## Usage

### Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values:

- FULL — creates a full backup that contains all the data files of the cluster to be restored.
- DELTA — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- PAGE — creates an incremental backup based on the WAL files that have been generated since the previous full or incremental backup was taken. Only changed blocks are read from data files.
- PTRACK — creates an incremental backup tracking page changes on the fly.

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. You must create at least one full backup before taking incremental ones.

### ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

### STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During [backup](#) `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using [continuous archiving](#), STREAM backups can still be useful in the following cases:

- STREAM backups can be restored on the server that has no file access to WAL archive.
- STREAM backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in STREAM mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

### Page Validation

If [data checksums](#) are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 100 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

### External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the `set-config` command with the `--external-dirs` option.

## Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance instance_name]] [-D data_dir] [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck\\_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

## Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running `backup` and `restore` commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the `validate` command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify *backup\_id* via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If *backup\_id* is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `PT8XFX` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name -i PT8XFX --recovery-target-time="2017-05-18 14:18:11+03"
```

If you specify the *backup\_id* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

## Restoring a Cluster

To restore the database cluster from a backup, run the `restore` command with at least the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -i backup_id
```

where:

- *backup\_dir* is the backup catalog that stores all backup files and meta information.
- *instance\_name* is the backup instance for the cluster to be restored.
- *backup\_id* specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary\\_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a [STREAM](#) backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For [ARCHIVE](#) backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option.

Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -j 4 -
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg\\_probackup in the Remote Mode”](#).

### Note

By default, the [restore](#) command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

### Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the [restore](#) command.

To restore the database cluster from a backup in incremental mode, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -
I incremental_mode
```

Where *incremental\_mode* can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the *pg\_control* in the data directory to obtain redo LSN and redo TLI, which allows to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the *pg\_control* file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that *pg\_control* contain valid information. Therefore it is not recommended to use LSN mode in any situation, where *pg\_control* cannot be trusted or has been tampered with: after *pg\_resetxlog* execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, *pg\_probackup* will check, that postmaster in given destination directory is not running and *system-identifier* is the same as in the backup.

Suppose you want to return an old master as replica after switchover using incremental restore in LSN mode:

| Instance | Version | ID     | Recovery Time |                        | Mode   | WAL Mode | TLI   | Time   |
|----------|---------|--------|---------------|------------------------|--------|----------|-------|--------|
| Data     | WAL     | Zratio | Start LSN     | Stop LSN               | Status |          |       |        |
| node     | 12      |        | QBRNBP        | 2020-06-11 17:40:58+03 | DELTA  | ARCHIVE  | 16/15 | 40s    |
| 194MB    | 16MB    | 8.26   | 15/2C000028   | 15/2D000128            | OK     |          |       |        |

INFO: Restore of backup QBRNBP completed.
```

### Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

### Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

### Note

The `template0` and `template1` databases are always restored.

### Note

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the `hot_standby` parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

## Performing Point-in-Time (PITR) Recovery

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the `restore` command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-time="2017-05-18 14:18:11+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-  
target='immediate'
```

## Using pg\_probackup in the Remote Mode

pg\_probackup supports the remote mode that allows to perform backup and restore operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have pg\_probackup installed on both systems.

### Note

pg\_probackup relies on passwordless SSH connection for communication between the hosts.

The typical workflow is as follows:

- On your backup host, configure pg\_probackup as explained in the section [Installation and Setup](#). For the [add-instance](#) and [set-config](#) commands, make sure to specify [remote options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the [archive-push](#) and [archive-get](#) commands, you must specify the [remote options](#) that point to the backup host with the backup catalog.
- Run [backup](#) or [restore](#) commands with [remote options on the backup host](#). pg\_probackup connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address 192.168.0.2 on behalf of the postgres user via SSH connection through port 2302, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --remote-  
user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address 192.168.0.2 on behalf of the postgres user via SSH connection through port 2302, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --  
remote-host=192.168.0.2 --remote-port=2302
```

Restoring an ARCHIVE backup or performing PITR in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user postgres on host with address 192.168.0.2 via port 2302 and user backup on backup catalog host with address 192.168.0.3 via port 2303, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres  
--remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-  
port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --  
instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3  
--remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres
--remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/
pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p
--wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

### Note

The remote mode is currently unavailable for Windows systems.

## Running pg\_probackup on Parallel Threads

[backup](#), [restore](#), [merge](#), [delete](#), [catchup](#), [checkdb](#), and [validate](#) processes can be executed on several parallel threads. This can significantly speed up `pg_probackup` operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL -j 4
```

### Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

## Configuring pg\_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune `pg_probackup` configuration.

For example, [backup](#) and [checkdb](#) commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

### Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance instance_name
```

You can override the settings defined in `pg_probackup.conf` when running `pg_probackup` [commands](#) via the corresponding environment variables and/or command line options.

## Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent `pg_probackup` commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default `pg_probackup` tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

## Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

## Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

| =====    |         |            |               |             |        |         |          |     |        |      |

For each backup, the following information is provided:

- Instance — the instance name.
- Version — Postgres Pro major version.
- ID — the backup identifier.
- Recovery time — the earliest moment for which you can restore the state of the database cluster.
- Mode — the method used to take this backup. Possible values: FULL, PAGE, DELTA, PTRACK.
- WAL Mode — WAL delivery mode. Possible values: STREAM and ARCHIVE.
- TLI — timeline identifiers of the current backup and its parent.

- **Time** — the time it took to perform the backup.
- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For **STREAM** backups, the total size of the backup can be calculated as **Data** + **WAL**.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.
- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
  - **OK** — the backup is complete and valid.
  - **DONE** — the backup is complete, but was not validated.
  - **RUNNING** — the backup is in progress.
  - **MERGING** — the backup is being merged.
  - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
  - **DELETING** — the backup files are being deleted.
  - **CORRUPT** — some of the backup files are corrupt.
  - **ERROR** — the backup was aborted because of an unexpected error.
  - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.

You can restore the cluster from the backup only if the backup status is **OK** or **DONE**.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = zlib
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
wal-block-size = 8192
checksum-version = 1
program-version = 2.1.3
server-version = 10

#Result backup info
timelineid = 1
start-lsn = 0/04000028
stop-lsn = 0/040000f8
start-time = '2017-05-16 12:57:29'
end-time = '2017-05-16 12:57:31'
recovery-xid = 597
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-05-16 12:57:31'
data-bytes = 22288792
wal-bytes = 16777216
```

```
uncompressed-bytes = 39961833
pgdata-bytes = 39859393
status = OK
parent-backup-id = 'PT8XFX'
primary_conninfo = 'user=backup passfile=/var/lib/pgsql/.pgpass port=5432
sslmode=disable sslcompression=1 target_session_attrs=any'
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on standby? Possible values: `1`, `0`.
- `block-size` — the [block\\_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data\\_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: `1`, `0`.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup meta-information.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",
    "backups": [
      {
        "id": "PT91HZ",
        "parent-backup-id": "PT8XFX",

```

### Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive
```

**pg\_probackup** displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
```

| TLI      | Parent TLI | Switchpoint | Min Segno                         | Max Segno                         | N  |
|----------|------------|-------------|-----------------------------------|-----------------------------------|----|

|          | 8774kB     | 19.00 1     | OK                                |                                   |    |

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zratio** — compression ratio calculated as  $N \text{ segments} * wal\_segment\_size * wal\_block\_size / \text{Size}$ .
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
  - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
  - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive --format=json
```

The sample output is as follows:

```

```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

### Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

## Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance instance_name --retention-redundancy=2
--retention-window=7
```

To clean up the backup catalog in accordance with retention policy, you have to run the [delete](#) command with [retention flags](#), as shown below, or use the [backup](#) command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running [backup](#) or [delete](#) commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 7, and you have the following backups available on April 10, 2019:

```
BACKUP INSTANCE 'node'
```

```
=====
Instance  Version  ID          Recovery time          Mode  WAL    TLI  Time   Data
WAL  Zratio  Start LSN   Stop LSN    Status
=====
node      10      P7XDHR      2019-04-10 05:27:15+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/18000059  0/18000197  OK
```

## Additional Supplied Programs

```

node      10      P7XDQV  2019-04-08 05:32:59+03  PAGE  STREAM  1/0   11s   19MB
16MB     1.0    0/15000060  0/15000198  OK
node      10      P7XDJA  2019-04-03 05:28:36+03  DELTA  STREAM  1/0   21s   32MB
16MB     1.0    0/13000028  0/13000198  OK
-----retention
window-----
node      10      P7XDHU  2019-04-02 05:27:59+03  PAGE  STREAM  1/0   31s   33MB
16MB     1.0    0/11000028  0/110001D0  OK
node      10      P7XDHB  2019-04-01 05:27:15+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/F0000028  0/F000198   OK
node      10      P7XDFT  2019-03-29 05:26:25+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/D0000028  0/D000198   OK

```

Even though P7XDHB and P7XDHU backups are outside the retention window, they cannot be removed as it invalidates the succeeding incremental backups P7XDJA and P7XDQV that are still required, so, if you run the [delete](#) command with the `--delete-expired` flag, only the P7XDFT full backup will be removed.

With the `--merge-expired` option, the P7XDJA backup is merged with the underlying P7XDHU and P7XDHB backups and becomes a full one, so there is no need to keep these expired backups anymore:

```
pg_probackup delete -B backup_dir --instance node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

```

=====
Instance  Version  ID      Recovery time      Mode  WAL      TLI  Time  Data
WAL  Zratio  Start LSN   Stop LSN      Status
=====
node      10      P7XDHR  2019-04-10 05:27:15+03  FULL  STREAM  1/0   11s   200MB
16MB     1.0    0/18000059  0/18000197  OK
node      10      P7XDQV  2019-04-08 05:32:59+03  PAGE  STREAM  1/0   11s   19MB
16MB     1.0    0/15000060  0/15000198  OK
node      10      P7XDJA  2019-04-03 05:28:36+03  FULL  STREAM  1/0   21s   32MB
16MB     1.0    0/13000028  0/13000198  OK

```

The Time field for the merged backup displays the time required for the merge.

### Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --expire-
time="2020-01-01 00:00:00+03"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the [backup](#) command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --ttl=30d
pg_probackup backup -B backup_dir --instance instance_name -b FULL --expire-
time="2020-01-01 00:00:00+03"
```

To check if the backup is pinned, run the [show](#) command:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-01-01 00:00:00+03'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=0
```

### Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

### Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the [set-config](#) command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the [delete](#) or [backup](#) command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the [delete](#) and [backup](#) commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance node
```

```
BACKUP INSTANCE 'node'
```

| Instance | Version | ID         | Recovery Time          | Mode   | WAL Mode | TLI | Time | Data  |
|----------|---------|------------|------------------------|--------|----------|-----|------|-------|
| WAL      | Zratio  | Start LSN  | Stop LSN               | Status |          |     |      |       |
| node     | 11      | PZ9442     | 2019-10-12 10:43:21+03 | DELTA  | STREAM   | 1/0 | 10s  | 121kB |
| 16MB     | 1.00    | 0/46000028 | 0/46000160             | OK     |          |     |      |       |
| node     | 11      | PZ943L     | 2019-10-12 10:43:04+03 | FULL   | STREAM   | 1/0 | 10s  | 180MB |
| 32MB     | 1.00    | 0/44000028 | 0/44000160             | OK     |          |     |      |       |
| node     | 11      | PZ7YR5     | 2019-10-11 19:49:56+03 | DELTA  | STREAM   | 1/1 | 10s  | 112kB |
| 32MB     | 1.00    | 0/41000028 | 0/41000160             | OK     |          |     |      |       |
| node     | 11      | PZ7YMP     | 2019-10-11 19:47:16+03 | DELTA  | STREAM   | 1/1 | 10s  | 376kB |
| 32MB     | 1.00    | 0/3E000028 | 0/3F0000B8             | OK     |          |     |      |       |
| node     | 11      | PZ7YK2     | 2019-10-11 19:45:45+03 | FULL   | STREAM   | 1/0 | 11s  | 180MB |
| 16MB     | 1.00    | 0/3C000028 | 0/3C000198             | OK     |          |     |      |       |
| node     | 11      | PZ7YFO     | 2019-10-11 19:43:04+03 | FULL   | STREAM   | 1/0 | 10s  | 30MB  |
| 16MB     | 1.00    | 0/20000028 | 0/200ADD8              | OK     |          |     |      |       |

You can check the state of the WAL archive by running the [show](#) command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance node --archive
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint  Min Segno          Max Segno          N
segments Size  Zratio  N backups  Status
=====
1     0          0/0          000000010000000000000001  000000010000000000000047  71
      36MB  31.00   6          OK
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint  Min Segno          Max Segno          N
segments Size  Zratio  N backups  Status
=====
1     0          0/0          000000010000000000000002  000000010000000000000047  70
      34MB  32.00   6          OK
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint  Min Segno          Max Segno          N
segments Size  Zratio  N backups  Status
=====
1     0          0/0          000000010000000000000046  000000010000000000000047  2
      143kB 228.00  6          OK
```

Alternatively, you can use the `--wal-depth` option with the [backup](#) command:

```
pg_probackup backup -B backup_dir --instance node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI   Parent TLI   Switchpoint  Min Segno          Max Segno          N
segments Size  Zratio  N backups  Status
=====
1     0          0/0          000000010000000000000048  000000010000000000000049  1
      72kB  228.00  7          OK
```

## Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and

removing all the outdated backups, but it allows to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the [remote](#) mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the [show](#) command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

## Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

## Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the [catchup](#) command. It can be useful in the following cases:

- To add a new standby server.

Usually, [pg\\_basebackup](#) is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with master.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with master and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from master.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands `CREATE TABLESPACE/DROP TABLESPACE` cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source instance server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK catchup mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source instance server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the `catchup` command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where `catchup_mode` can take one of the following values: FULL, DELTA, or PTRACK.

- FULL — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- DELTA — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- PTRACK — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

### Warning

PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set [STREAM](#) WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the instance server via replication protocol.

You can use [connection options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK  
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-  
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --  
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --  
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

## Command-Line Reference

### Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

#### version

```
pg_probackup version
```

Prints `pg_probackup` version.

#### help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

#### init

```
pg_probackup init -B backup_dir [--help]
```

Initializes the backup catalog in *backup\_dir* that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified *backup\_dir* already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message.

For details, see the section [Initializing the Backup Catalog](#).

#### add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name [--help]
```

Initializes a new backup instance inside the backup catalog *backup\_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data\_dir* data directory.

For details, see the section [Adding a New Backup Instance](#).

#### del-instance

```
pg_probackup del-instance -B backup_dir --instance instance_name [--help]
```

Deletes all backups and WAL files associated with the specified instance.

#### set-config

```
pg_probackup set-config -B backup_dir --instance instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

#### set-backup

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [--help]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If *backup\_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

For all available pinning settings, see the section [Pinning Options](#).

#### show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
```

Displays the contents of the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

To edit `pg_probackup.conf`, use the [set-config](#) command.

#### show

```
pg_probackup show -B backup_dir
[--help] [--instance instance_name [-i backup_id | --archive]] [--format=plain|json]
[--no-color]
```

Shows the contents of the backup catalog. If *instance\_name* and *backup\_id* are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

## backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance instance_name
[--help] [-j num_threads] [--progress]
[-C] [--stream [-S slot_name] [--temp-slot]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options]
```

Creates a backup copy of the Postgres Pro instance.

-b *mode*

--backup-mode=*mode*

Specifies the backup mode to use. Possible values are:

- FULL — creates a full backup that contains all the data files of the cluster to be restored.
- DELTA — reads all data files in the data directory and creates an incremental backup for pages that have changed since the previous backup.
- PAGE — creates an incremental PAGE backup based on the WAL files that have changed since the previous full or incremental backup was taken.
- PTRACK — creates an incremental PTRACK backup tracking page changes on the fly.

-C

--smooth-checkpoint

Spreads out the checkpoint over a period of time. By default, pg\_probackup tries to complete the checkpoint as soon as possible.

--stream

Makes a [STREAM](#) backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

--temp-slot

Creates a temporary physical replication slot for streaming WAL from the backed up Postgres Pro instance. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the --stream flag. The default slot name is pg\_probackup\_slot, which can be changed using the --slot/-S option.

-S *slot\_name*

--slot=*slot\_name*

Specifies the replication slot for WAL streaming. This option can only be used together with the --stream flag.

--backup-pg-log

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

-E *external\_directory\_path*

--external-dirs=*external\_directory\_path*

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and

configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If `backup_note` contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

Additionally, [connection options](#), [retention options](#), [pinning options](#), [remote mode options](#), [compression options](#), [logging options](#), and [common options](#) can be used.

For details on usage, see the section [Creating a Backup](#).

## restore

```
pg_probackup restore -B backup_dir --instance instance_name
[--help] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options]
```

Restores the Postgres Pro instance from a backup copy located in the `backup_dir` backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

`-R`

`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary\\_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings in-

to the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the `primary_conninfo` parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`

`--primary-slot-name=slot_name`

Sets the `primary_slot_name` parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`

`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (`=`), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`

Relocates an external directory included into the backup from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (`=`), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--restore-command=cmdline`

Sets the `restore_command` parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, `incremental restore` with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the `restore` command again.

```
-X wal_dir
--waldir=wal_dir
```

Specifies the directory where WAL should be stored.

Additionally, [recovery target options](#), [remote mode options](#), [remote WAL archive options](#), [logging options](#), [partial restore options](#), and [common options](#) can be used.

For details on usage, see the section [Restoring a Cluster](#).

#### checkdb

```
pg_probackup checkdb
[-B backup_dir] [--instance instance_name] [-D data_dir]
[--help] [-j num_threads] [--progress]
[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]
[connection_options] [logging_options]
```

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

`--amcheck`

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of `amcheck` installed.

`--checkunique`

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the `amcheck` extension is installed in the database.

The verification of unique constraints is only possible if in the version of the `amcheck` extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

`--heapallindexed`

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the `amcheck/amcheck_next` extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

`--skip-block-validation`

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

Additionally, [connection options](#) and [logging options](#) can be used.

For details on usage, see the section [Verifying a Cluster](#).

#### validate

```
pg_probackup validate -B backup_dir
[--help] [--instance instance_name] [-i backup_id]
[-j num_threads] [--progress]
[--skip-block-validation]
[recovery_target_options] [logging_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If `instance_name` is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the `instance_name` without any additional options, `pg_probackup` validates all the backups available for this

backup instance. If you specify the *instance\_name* with a [recovery target option](#) and/or a *backup\_id*, `pg_probackup` checks whether it is possible to restore the cluster using these options.

For details, see the section [Validating a Backup](#).

### merge

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
[--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

`--no-validate`

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the section [Merging Backups](#).

### delete

```
pg_probackup delete -B backup_dir --instance instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options]
```

Deletes backup with specified *backup\_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

### archive-push

```
pg_probackup archive-push -B backup_dir --instance instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance\_name* and system-identifier. If parameters of the backup instance and the clus-

ter do not match, this command fails with the following error message: Refuse to push WAL segment segment\_name into archive. Instance parameters mismatch.

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive\\_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For details, see sections [Archiving Options](#) and [Compression Options](#).

#### **archive-get**

```
pg_probackup archive-get -B backup_dir --instance instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--help] [remote_options] [logging_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually.

To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For details, see section [Archiving Options](#).

#### **catchup**

```
pg_probackup catchup -b catchup_mode  
--source-pgdata=path_to_pgdata_on_remote_server  
--destination-pgdata=path_to_local_dir  
[--help] [-j | --threads=num_threads] [--stream] [--dry-run]  
[--temp-slot] [-P | --perm-slot] [-S | --slot=slot_name]  
[--exclude-path=PATHNAME]  
[-T OLDDIR=NEWDIR]  
[connection_options] [remote_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

```
-b catchup_mode  
--backup-mode=catchup_mode
```

Specifies the catchup mode to use. Possible values are:

- `FULL` — creates a full copy of the Postgres Pro instance.

- **DELTA** — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- **PTRACK** — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

### Warning

PTRACK catchup mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

`--source-pgdata=path_to_pgdata_on_remote_server`

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

`--destination-pgdata=path_to_local_dir`

Specifies the path to the local data directory to copy to.

`-j num_threads`

`--threads=num_threads`

Sets the number of parallel threads for `catchup` process.

`--stream`

Copies the instance in **STREAM** WAL delivery mode, including all the necessary WAL files by streaming them from the instance server via replication protocol.

`--dry-run`

Displays the total size of the files to be transferred by `catchup`. This flag initiates a trial run of `catchup`, which does not actually create, delete or move files on disk. WAL streaming is skipped with `--dry-run`. This flag also allows you to check that all the options are correct and cloning/synchronising is ready to run.

`-x=path_prefix`

`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

### Warning

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`, which can be changed using the `--slot/-S` option.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together

with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

```
-S slot_name
--slot=slot_name
```

Specifies the replication slot for WAL streaming. This option can only be used together with the `--stream` flag.

```
-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR
```

Relocates the tablespace from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (`=`), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

Additionally, [connection options](#), [remote mode options](#) can be used.

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

## Options

This section describes command-line options for `pg_probackup` commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the `pg_probackup.conf` configuration file located in the backup catalog.

For details, see [the section called "Configuring pg\\_probackup"](#).

If an option is specified using more than one method, command-line input has the highest priority, while the `pg_probackup.conf` settings have the lowest priority.

## Common Options

The list of general options.

```
-B directory
--backup-path=directory
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the `pg_probackup` commands, you are recommended to specify it once in the `BACKUP_PATH` environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory
--pgdata=directory
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the [add-instance](#) command. Other commands can take its value from the `PGDATA` environment variable, or from the `pg_probackup.conf` configuration file.

```
-i backup_id
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

`--progress`

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

### Recovery Target Options

If [continuous WAL archiving](#) is configured, you can use one of these options together with [restore](#) or [validate](#) commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. This is the default behavior for ARCHIVE backups.

`--recovery-target-timeline=timeline`

Specifies a particular timeline to be used for recovery. By default, the timeline of the specified backup is used.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed. Can be used only when restoring a database cluster of major version 10 or higher.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2020-01-01 00:00:00+03"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-name`, `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery\\_target\\_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery\\_target\\_action](#) the server should take when the recovery target is reached.

Default: `pause`

### Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

### Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2020-01-01 00:00:00+03"`

### Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

### Note

All console log messages are going to `stderr`, so the output of `show` and `show-config` commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `none`

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-format-console=log_format`

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the `set-config` command and that the `backup` command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.

- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=log_format`

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: `plain`

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: 0

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

### Connection Options

You can use these options together with `backup`, `catchup`, and `checkdb` commands.

All `libpq` environment variables are supported.

`-d dbname`

`--pgdatabase=dbname`

`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h host`

`--pghost=host`

`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: `localhost`

`-p port`

`--pgport=port`

`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

`-U username`  
`--pguser=username`  
PGUSER

User name to connect as.

`-w`  
`--no-password`

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a [.pgpass](#) file or `PGPASSWORD` environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Forces a password prompt. (Deprecated)

### Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

`--compress-algorithm=compression_algorithm`

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `pglz`, and `none`. If set to `zlib` or `pglz`, this option enables compression. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

Default: `none`

`--compress-level=compression_level`

Defines compression level (0 through 9, 0 being no compression and 9 being best compression). This option can be used together with the `--compress-algorithm` option.

Default: `1`

`--compress`

Alias for `--compress-algorithm=zlib` and `--compress-level=1`.

### Archiving Options

These options can be used with the [archive-push](#) command in the [archive\\_command](#) setting and the [archive-get](#) command in the [restore\\_command](#) setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in [archive\\_command](#) and [restore\\_command](#). Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in [archive\\_command](#) and [restore\\_command](#). Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, [archive-push](#) reports that a WAL segment already exists, and aborts the

operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Sets the maximum number of files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with `archive-push` command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with `archive-push` command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with `archive-push` command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with `archive-get` command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with `archive-get` command.

### Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with `add-instance`, `set-config`, `backup`, `catchup`, `restore`, `archive-push`, and `archive-get` commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg\\_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh\\_config manual page](#).

### Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in `archive-get` used in the [restore\\_command](#) command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

### Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the [restore](#) command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

### Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the [restore](#) command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

## Replica Options

This section describes the options related to taking a backup from standby.

### Note

Starting from `pg_probackup 2.0.24`, backups can be taken from standby without connecting to the master server, so these options are no longer required. In lower versions, `pg_probackup` had to connect to the master to determine recovery time — the earliest moment for which you can restore a consistent state of the database cluster.

`--master-db=dbname`

Deprecated. Specifies the name of the database on the master server to connect to. The connection is used only for managing the backup process, so you can connect to any existing database. Can be set in the `pg_probackup.conf` using the [set-config](#) command.

Default: `postgres`, the default Postgres Pro database

`--master-host=host`

Deprecated. Specifies the host name of the system on which the master server is running.

`--master-port=port`

Deprecated. Specifies the TCP port or the local Unix domain socket file extension on which the master server is listening for connections.

Default: `5432`, the Postgres Pro default port

`--master-user=username`

Deprecated. User name to connect as.

Default: `postgres`, the Postgres Pro default user name

`--replica-timeout=timeout`

Deprecated. Wait time for WAL segment streaming via replication, in seconds. By default, `pg_probackup` waits 300 seconds. You can also define this parameter in the `pg_probackup.conf` configuration file using the [set-config](#) command.

Default: `300 sec`

## How-To

All examples below assume the remote mode of operations via SSH. If you are planning to run backup and restore operation locally, skip the “Setup passwordless SSH connection” step and omit all `--remote-*` options.

Examples are based on Ubuntu 18.04, Postgres Pro 11, and `pg_probackup 2.2.0`.

- `backup` — Postgres Pro role used for connection to Postgres Pro cluster.
- `backupdb` — database used for connection to Postgres Pro cluster.
- `backup_host` — host with backup catalog.
- `backupman` — user on `backup_host` running all `pg_probackup` operations.
- `/mnt/backups` — directory on `backup_host` where backup catalog is stored.
- `postgres_host` — host with Postgres Pro cluster.
- `postgres` — user on `postgres_host` that has started the Postgres Pro cluster.
- `/var/lib/postgresql/11/main` — Postgres Pro data directory on `postgres_host`.

## Minimal Setup

This scenario illustrates setting up standalone FULL and DELTA backups.

1. **Set up passwordless SSH connection from backup\_host to postgres\_host:**

```
[backupman@backup_host] ssh-copy-id postgres@postgres_host
```

2. **Configure your Postgres Pro cluster.**

For security purposes, it is recommended to use a separate database for backup operations.

```
postgres=#  
CREATE DATABASE backupdb;
```

Connect to the backupdb database, create the probackup role, and grant the following permissions to this role:

```
backupdb=#  
BEGIN;  
CREATE ROLE backup WITH LOGIN REPLICATION;  
GRANT USAGE ON SCHEMA pg_catalog TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO  
backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;  
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;  
COMMIT;
```

3. **Initialize the backup catalog:**

```
[backupman@backup_host]$ pg_probackup-11 init -B /mnt/backups  
INFO: Backup catalog '/mnt/backups' successfully initied
```

4. **Add instance pg-11 to the backup catalog:**

```
[backupman@backup_host]$ pg_probackup-11 add-instance -B /mnt/backups --  
instance pg-11 --remote-host=postgres_host --remote-user=postgres -D /var/lib/  
postgresql/11/main  
INFO: Instance 'node' successfully initied
```

5. **Take a FULL backup:**

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11  
-b FULL --stream --remote-host=postgres_host --remote-user=postgres -U backup -d  
backupdb  
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YK2,  
backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: none,  
compress-level: 1  
INFO: Start transferring data files  
INFO: Data files are transferred  
INFO: wait for pg_stop_backup()  
INFO: pg_stop_backup() successfully executed  
INFO: Validating backup PZ7YK2  
INFO: Backup PZ7YK2 data files are valid  
INFO: Backup PZ7YK2 resident size: 196MB
```

```
INFO: Backup PZ7YK2 completed
```

## 6. Let's take a look at the backup catalog:

```
[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance pg-11
```

```
BACKUP INSTANCE 'pg-11'
```

```
=====
Instance  Version  ID          Recovery Time          Mode  WAL Mode  TLI  Time
Data     WAL   Zratio  Start LSN  Stop LSN   Status
=====
node      11      PZ7YK2  2019-10-11 19:45:45+03  FULL  STREAM    1/0  11s
180MB    16MB    1.00    0/3C000028  0/3C000198  OK
=====
```

## 7. Take an incremental backup in the DELTA mode:

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11 -b delta --stream --remote-host=postgres_host --remote-user=postgres -U backup -d backupdb
```

```
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YMP, backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none, compress-level: 1
```

```
INFO: Parent backup: PZ7YK2
```

```
INFO: Start transferring data files
```

```
INFO: Data files are transferred
```

```
INFO: wait for pg_stop_backup()
```

```
INFO: pg_stop_backup() successfully executed
```

```
INFO: Validating backup PZ7YMP
```

```
INFO: Backup PZ7YMP data files are valid
```

```
INFO: Backup PZ7YMP resident size: 32MB
```

```
INFO: Backup PZ7YMP completed
```

## 8. Let's add some parameters to pg\_probackup configuration file, so that you can omit them from the command line:

```
[backupman@backup_host] pg_probackup-11 set-config -B /mnt/backups --instance pg-11 --remote-host=postgres_host --remote-user=postgres -U backup -d backupdb
```

## 9. Take another incremental backup in the DELTA mode, omitting some of the previous parameters:

```
[backupman@backup_host] pg_probackup-11 backup -B /mnt/backups --instance pg-11 -b delta --stream
```

```
INFO: Backup start, pg_probackup version: 2.2.0, instance: node, backup ID: PZ7YR5, backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none, compress-level: 1
```

```
INFO: Parent backup: PZ7YMP
```

```
INFO: Start transferring data files
```

```
INFO: Data files are transferred
```

```
INFO: wait for pg_stop_backup()
```

```
INFO: pg_stop_backup() successfully executed
```

```
INFO: Validating backup PZ7YR5
```

```
INFO: Backup PZ7YR5 data files are valid
```

```
INFO: Backup PZ7YR5 resident size: 32MB
```

```
INFO: Backup PZ7YR5 completed
```

## 10. Let's take a look at the instance configuration:

```
[backupman@backup_host] pg_probackup-11 show-config -B /mnt/backups --instance pg-11
```

```
# Backup instance information
```

```
pgdata = /var/lib/postgresql/11/main
```

```
system-identifier = 6746586934060931492
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Replica parameters
replica-timeout = 5min
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-format-console = PLAIN
log-format-file = PLAIN
log-filename = pg_probackup.log
log-rotation-size = 0
log-rotation-age = 0
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
```

Note that we are getting the default values for other options that were not overwritten by the `set-config` command.

## 11. Let's take a look at the backup catalog:

```
[backupman@backup_host] pg_probackup-11 show -B /mnt/backups --instance pg-11
```

| Instance | Version | ID     | Recovery Time |            |             | Mode   | WAL Mode | TLI | Time |
|----------|---------|--------|---------------|------------|-------------|--------|----------|-----|------|
| Data     | WAL     | Zratio | Start         | LSN        | Stop LSN    | Status |          |     |      |

## Versioning

pg\_probackup follows *semantic* versioning.

## Authors

Postgres Professional, Moscow, Russia.

## Credits

pg\_probackup utility is based on pg\_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.

## pg\_repack

pg\_repack — utility and Postgres Pro Enterprise extension to reorganize tables

### Synopsis

```
pg_repack [option...] [dbname]
```

### Description

*pg\_repack* is a Postgres Pro Enterprise extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike `CLUSTER` and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. *pg\_repack* is efficient to boot, with performance comparable to using `CLUSTER` directly.

*pg\_repack* is a fork of the previous [https://github.com/reorg/pg\\_reorg](https://github.com/reorg/pg_reorg) project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

#### Note

Only superusers can use the utility.

#### Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

### Installation

On Linux systems, *pg\_repack* is provided together with Postgres Pro as a separate pre-built package and requires the `postgrespro-ent-11-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 17](#). On Windows systems, *pg\_repack* is automatically installed as part of Postgres Pro.

Once you have *pg\_repack* installed, load the *pg\_repack* extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove *pg\_repack* from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of *pg\_repack*, just drop the old version from the database as explained above and install the new version.

### Options

#### Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the *pg\_repack* extension is not installed will be skipped.

`-t table`  
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-c schema`  
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`  
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`  
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`  
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`  
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro Enterprise, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`  
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`  
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`  
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`  
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`  
`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration,

`pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-Z`  
`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

### Connection Options

`[-d] dbname`  
`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`  
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`  
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`  
`--username=username`

User name to connect as.

`-w`  
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`  
`--password`

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

### Generic Options

`-e`  
`--echo`

Echo the commands that `pg_repack` generates and sends to the server.

`-E level`  
`--elevel=level`

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

`--help`

Show help about `pg_repack` command line arguments, and exit.

`-V`

`--version`

Print the `pg_repack` version and exit.

## Environment

`PGDATABASE`

`PGHOST`

`PGPORT`

`PGUSER`

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 35.14](#)).

## Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

## Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
The SQL extension found in the database does not match the version required by the
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.
```

Define a `PRIMARY KEY` or a `UNIQUE` constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last `BEFORE` trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

ERROR: Another `pg_repack` command may be running on the table. Please try again later.

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

WARNING: Cannot create index "schema"."index\_xxxxx", already exists  
DETAIL: An invalid index may have been left behind by a previous `pg_repack` on the table which was interrupted. Please use `DROP INDEX "schema"."index_xxxxx"` to remove this index and try again.

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

## Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

## vacuumlo

`vacuumlo` — remove orphaned large objects from a Postgres Pro database

## Synopsis

```
vacuumlo [option...] dbname...
```

## Description

`vacuumlo` is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

## Options

`vacuumlo` accepts the following command-line arguments:

`-l limit`

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max\\_locks\\_per\\_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

`-n`

Don't remove anything, just show what would be done.

`-v`

Write a lot of progress messages.

`-V`

`--version`

Print the `vacuumlo` version and exit.

`-?`

`--help`

Show help about `vacuumlo` command line arguments, and exit.

`vacuumlo` also accepts the following command-line arguments for connection parameters:

`-h hostname`

Database server's host.

`-p port`

Database server's port.

`-U username`

User name to connect as.

`-w`

`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

-W

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing -W to avoid the extra connection attempt.

## Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

## Author

Peter Mount <peter@retap.org.uk>

## G.2. Server Applications

This section covers Postgres Pro Enterprise server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Enterprise distribution.

## mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics.

### Synopsis

mamonsu [-c | --config] [-d | --daemonize]  
  
mamonsu --version  
  
mamonsu --help
```

### Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

### Installation and Setup

#### Important

Before you start installation, attentively read [Compatibility Considerations](#).

To use `mamonsu`, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 17](#) and [Section 18.2](#) for Postgres Pro installation and setup instructions, respectively.

### Note

While `mamonsu` can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

A pre-built `mamonsu` package is provided together with Postgres Pro Enterprise, but has a separate installer. Once you have installed `mamonsu`, complete the following steps to set up metrics collection:

#### 1. Optionally, bootstrap `mamonsu`

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the `mamonsu` user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of `bootstrap`:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for `mamonsu`. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap `mamonsu`:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/mamonsu.conf -d  
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see [bootstrap](#). For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that `mamonsu` also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for `mamonsu` to work.

#### 2. Configure `mamonsu`

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

### Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

## 3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
  - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
  - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

### Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

## Command-Line Reference

### agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get metric_name`

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display `mamonsu` version.

### bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
[-c[ config_file] | --config[=config_file]]
[-x | --create-extensions] [connection_options]
```

Bootstrap `mamonsu`. This command can take the following options:

- `-M`
- Specify a non-privileged user that will own all `mamonsu` processes.
- `-c config_file`  
`--config=config_file`
- Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through `connection_options`.
- Default: `/etc/mamonsu/agent.conf`
- `-x`  
`--create-extensions`
- Create auxiliary extensions. The `pg_buffercache` extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the `pgpro_stats` extension and grant the right to execute them to the `mamonsu` user.
- `connection_options`
- Provide optional *command-line connection parameters*.

## export

Syntax:

```
mamonsu export config filename.conf [--add-plugins=plugin_directory]
mamonsu export template filename.xml [--add-plugins=plugin_directory]
                                     [--template-name=template_name]
                                     [--application=application_name]
                                     [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

- `--add-plugins=plugin_directory`
- Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.
- `--template-name=template_name`
- Specify the name of the template that will be displayed on the Zabbix server.
- Default: `PostgresPro-OS`, where *OS* is the name of your operating system
- `--application=application_name`
- Specify an identifier under which the collected metrics will be displayed on the Zabbix server.
- Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system
- `--old-zabbix`
- Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

## export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
```

```
[--plugin-type={pg | sys | all}]  
[--pg-version=version]  
[--config=config_file]
```

Export metrics configuration for use with the native *Zabbix agent*. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. *mamonsu* can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

## export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]  
                                              [--plugin-type={pg | sys | all}]  
                                              [--template-name=template_name]  
                                              [--application=application_name]  
                                              [--config=config_file]  
                                              [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin\_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: all

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

## report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

*connection\_options*

Provide optional *command-line connection parameters*.

## tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune *pgbadger* parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

*connection\_options*

Provide optional *command-line connection parameters*.

## upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

### **zabbix dashboard upload**

Syntax:

`mamonsu dashboard upload template_name`

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

### **zabbix item**

Syntax:

`mamonsu zabbix item {error | lastvalue | lastclock } host_name`

View the specified property of the latest metrics data received by Zabbix for the specified host.

### **zabbix version**

Syntax:

`mamonsu zabbix version`

Get the version of the Zabbix server that mamonsu is connected to.

### **zabbix host**

Syntax:

`mamonsu zabbix host list`  
`mamonsu zabbix host show host_name`  
`mamonsu zabbix host id host_name`  
`mamonsu zabbix host delete host_id`  
`mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address`  
`mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id`

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

### **zabbix hostgroup**

Syntax:

`mamonsu zabbix hostgroup list`  
`mamonsu zabbix hostgroup show hostgroup_name`  
`mamonsu zabbix hostgroup id hostgroup_name`  
`mamonsu zabbix hostgroup delete hostgroup_id`  
`mamonsu zabbix hostgroup create hostgroup_name`

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

## zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

## [--config] [--daemonize]

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

```
-d
--daemonize
```

Run in the background. Without it, mamonsu will run in the foreground.

## --version

Syntax:

```
mamonsu --version
```

Display mamonsu version.

## --help

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

## Connection Options

*connection\_options* provide command-line connection parameters for the target Postgres Pro cluster. *connection\_options* can be `--host`, `--port`, `--dbname` (`-d`), `--username` (`-U`), and `--password` (`-W`). The `--dbname` option should specify the *mamonsu\_database* created for monitoring purposes. Note that the `--username` (`-U`) option must specify a superuser that can access the cluster.

If you omit *connection\_options*, mamonsu checks the configuration file for the needed settings.

## Zabbix Server Actions

Using mamonsu, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object\_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show object_name`

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

## Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

### Important

Only `mamonsu` user can read and edit `agent.conf`.

All parameters must be specified in the `parameter = value` format.

## Connection Parameters

### [postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: `postgres`

password

The password for the specified user.

database

The database to connect to for metrics collection.

Default: postgres

host

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application\_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query\_timeout

[statement\\_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

#### **[system]**

The `[system]` section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to `True` or `False`, respectively.

Default: `True`

#### **[zabbix]**

The `[zabbix]` section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to `True` or `False`, respectively.

Default: `True`

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: 127.0.0.1

port

The port of the Zabbix server.

Default: 10051

timeout

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

#### **[agent]**

The `[agent]` section specifies the location of `mamonsu` and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the `agent` command.

Default: `True`

host

The address of the system on which `mamonsu` is running.

Default: 127.0.0.1

port

The port on which `mamonsu` is running.

Default: 10052

#### **[sender]**

The `[sender]` section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before `mamonsu` sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

### **Logging Parameters**

#### **[metric\_log]**

The `[metric_log]` section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metrics data in a text file. If this option is set to `True`, `mamonsu` creates the `localhost.log` file for storing metric values.

Default: `False`

directory

Specifies the directory where log files with metrics data will be stored.

Default: `/var/log/mamonsu`

max\_size\_mb

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to `localhost.log.archive`, and an empty `localhost.log` file is created.

Default: 1024

**[log]**

The `[log]` section specifies logging settings for mamonsu and can contain the following parameters:

`file`

Specifies the log filename, which can be preceded by the full path.

`level`

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

`format`

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

**Plugin Parameters****[plugins]**

The `[plugins]` section specifies custom plugins to be added for metrics collection and can contain the following parameters:

`enabled`

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

`directory`

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

**Individual Plugin Sections**

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the `Individual Plugin Sections` heading and edit its parameter values.

To disable any plugin you should set the `enabled` parameter to `False` and to enable it — set it to `True`. These values are case sensitive.

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
```

```
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

#### [preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 53.78](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The `interval` parameter allows you to change the metrics collection interval.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

#### [pgprobackup]

This plugin uses [pg\\_probackup](#) to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

The `interval` parameter allows you to change the metrics collection interval.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified *backup\_directory*.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

## Usage

### Collecting and Viewing Metrics Data

Once started, `mamonsu` begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

|                                                              |            |            |
|--------------------------------------------------------------|------------|------------|
| <code>system.memory[active]</code>                           | 7921004544 | 1564570818 |
| <code>system.memory[swap_cache]</code>                       | 868352     | 1564570818 |
| <code>pgsql.connections[idle]</code>                         | 6.0        | 1564570818 |
| <code>pgsql.archive_command[failed_trying_to_archive]</code> | 0          | 1564570818 |

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where *metric\_name* is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called “Logging Parameters”](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

## Adding Custom Plugins

You can extend mamonsu with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

## Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

## Managing Zabbix Server Settings from the Command Line

mamonsu enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

## 2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

## 3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

## 4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

## 5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host\_name* is the name of the host, *hostgroup\_id* and *template\_id* are the unique IDs returned in the previous step, and *mamonsu\_address* is the IP address of the system on which mamonsu runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

## Exporting Metrics for Native Zabbix Agent

Using mamonsu, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

### Important

To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

## 1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).

## 2. Generate a template for the native Zabbix agent:

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).

3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
  - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
  - For `{$PG_PATH}`, specify `psql` installation directory.

## Compatibility Considerations

If you want to upgrade `mamonsu` to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
  1. Install the new version of `mamonsu`.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of `mamonsu`, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.
  5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
  6. Create a new host for the same system and link the new template to it.
  7. Restart `mamonsu`. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
  1. Install the new version of `mamonsu`.
  2. Generate a new template for the Zabbix server.
  3. If you performed a bootstrap using the previous version of `mamonsu`, run the `bootstrap` command again.
  4. Upload the new template to the Zabbix server.
  5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
  6. Restart `mamonsu`. It will start collecting data. All the data collected earlier will be lost.

## pgbouncer

pgbouncer — a Postgres Pro connection pooler

### Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

### Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

#### Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

#### Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

#### Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

### Quick Start

Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch pgbouncer:

```
$ pgbouncer -d pgbouncer.ini
```

### Note

The above command does not work on Windows systems. Instead, pgbouncer must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to pgbouncer instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage pgbouncer by connecting to the special administration database pgbouncer and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

## Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

### Note

Does not work on Windows, pgbouncer needs to run as service there.

`-R, --reboot`

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

### Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

## Admin Console

The console is available by connecting as normal to the database `pgbouncer`:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

## Show Commands

The `SHOW` commands output information. Each command is described below.

### SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

`total_xact_count`

Total number of SQL transactions pooled by pgbouncer.

`total_query_count`

Total number of SQL queries pooled by pgbouncer.

`total_received`

Total volume in bytes of network traffic received by pgbouncer.

`total_sent`

Total volume in bytes of network traffic sent by pgbouncer.

`total_xact_time`

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

`total_query_time`

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

`total_wait_time`

Time spent by clients waiting for a server, in microseconds.

`avg_xact_count`

Average transactions per second in last stat period.

`avg_query_count`

Average queries per second in last stat period.

`avg_recv`

Average received (from clients) bytes per second.

`avg_sent`

Average sent (to clients) bytes per second.

`avg_xact_time`

Average transaction duration, in microseconds.

`avg_query_time`

Average query duration, in microseconds.

`avg_wait_time`

Time spent by clients waiting for a server, in microseconds (average per second).

#### **SHOW STATS\_TOTALS**

Subset of `SHOW STATS` showing the total values (`total_`).

#### **SHOW STATS\_AVERAGES**

Subset of `SHOW STATS` showing the average values (`avg_`).

#### **SHOW TOTALS**

Like `SHOW STATS` but aggregated across all databases.

## SHOW SERVERS

type

S, for server.

user

User name pgbouncer uses to connect to server.

database

Database name.

state

State of the pgbouncer server connection, one of active, idle, used, tested, or new.

addr

IP address of Postgres Pro server.

port

Port of Postgres Pro server.

local\_addr

Connection start address on local machine.

local\_port

Connection start port on local machine.

connect\_time

When the connection was made.

request\_time

When last request was issued.

wait

Current waiting time in seconds.

wait\_us

Microsecond part of the current waiting time.

close\_needed

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or RECONNECT was issued.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote\_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should

be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

#### **SHOW CLIENTS**

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of `active` or `waiting`.

addr

IP address of the client.

port

Source port of the client.

local\_addr

Connection end address on local machine.

local\_port

Connection end port on local machine.

connect\_time

Timestamp of connect time.

request\_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait\_us

Microsecond part of the current waiting time.

close\_needed

Not used for clients.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

`remote_pid`

Process ID, in case client connects over Unix socket and OS supports getting it.

`tls`

A string with TLS connection information, or empty if not using TLS.

#### **SHOW POOLS**

A new pool entry is made for each couple of (database, user).

`database`

Database name.

`user`

User name.

`cl_active`

Client connections that are linked to server connection and can process queries.

`cl_waiting`

Client connections that have sent queries but have not yet got a server connection.

`cl_cancel_req`

Client connections that have not forwarded query cancellations to the server yet.

`sv_active`

Server connections that are linked to a client.

`sv_idle`

Server connections that are unused and immediately usable for client queries.

`sv_used`

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

`sv_tested`

Server connections that are currently running either `server_reset_query` or `server_check_query`.

`sv_login`

Server connections currently in the process of logging in.

`maxwait`

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

`maxwait_us`

Microsecond part of the maximum waiting time.

`pool_mode`

The pooling mode in use.

## SHOW LISTS

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free\_clients

Count of free clients.

used\_clients

Count of used clients.

login\_clients

Count of clients in login state.

free\_servers

Count of free servers.

used\_servers

Count of used servers.

dns\_names

Count of DNS names in the cache.

dns\_zones

Count of DNS zones in the cache.

dns\_queries

Count of in-flight DNS queries.

dns\_pending

Not used.

## SHOW USERS

name

The user name.

pool\_mode

The user's override `pool_mode`, or `NULL` if the default will be used instead.

## SHOW DATABASES

name

Name of configured database entry.

host

Host pgbouncer connects to.

`port`

Port `pgbouncer` connects to.

`database`

Actual database name `pgbouncer` connects to.

`force_user`

When the user is part of the connection string, the connection between `pgbouncer` and `Postgres Pro` is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

#### **SHOW FDS**

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

#### **Note**

This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while `pgbouncer` is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

user

User of the connection using the FD.

database

Database of the connection using the FD.

addr

IP address of the connection using the FD, `unix` if a Unix socket is used.

port

Port used by the connection using the FD.

cancel

Cancel key for this connection.

link

File descriptor for corresponding server/client. `NULL` if idle.

#### **SHOW SOCKETS, SHOW ACTIVE\_SOCKETS**

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

#### **SHOW CONFIG**

Show the current configuration settings, one per row, with the following columns:

key

Configuration variable name.

value

Configuration value.

default

Configuration default value.

changeable

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

#### **SHOW MEM**

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

#### **SHOW DNS\_HOSTS**

Show host names in DNS cache.

hostname

Host name.

ttd

How many seconds until next lookup.

addrs

Comma separated list of addresses.

**SHOW DNS\_ZONES**

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

**SHOW VERSION**

Show the pgbouncer version string.

**Process Controlling Commands****PAUSE [db]**

pgbouncer tries to disconnect from all servers, first waiting for all queries to complete. The command will not return before all queries are finished. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

**DISABLE db**

Reject all new client connections on the given database.

**ENABLE db**

Allow new client connections after a previous `DISABLE` command.

**RECONNECT db**

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed, because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimaster replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

**KILL db**

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

**SUSPEND**

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

#### **RESUME [*db*]**

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

#### **SHUTDOWN**

The pgbouncer process will exit.

#### **RELOAD**

The pgbouncer process will reload its configuration file and update changeable settings.

PgBouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

#### **WAIT\_CLOSE [*db*]**

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

#### **Other Commands**

##### **SET *key* = *arg***

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

#### **Signals**

##### **SIGHUP**

Reload config. Same as issuing the command `RELOAD` on the console.

##### **SIGINT**

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

##### **SIGTERM**

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

##### **SIGUSR1**

Same as issuing `PAUSE` on the console.

##### **SIGUSR2**

Same as issuing `RESUME` on the console.

#### **Libevent Settings**

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, `libevent` displays the kernel notification method that it uses.

### **pgbouncer.ini Configuration File**

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

#### **Generic Settings**

##### `logfile`

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation `kill -HUP` or on console `RELOAD`; should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

##### `pidfile`

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

##### `listen_addr`

Specifies a list of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

##### `listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

##### `unix_socket_dir`

Specifies location for Unix sockets. Applies to both listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with `@` specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (`-R`) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: `/tmp` (empty on Windows)

##### `unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

##### `unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

`user`

If set, specifies the Unix user to change to after startup. Works only if `pgbouncer` is started as root or if it's already running as given user.

Not supported on Windows.

Default: not set

`auth_file`

The name of the file to load user names and passwords from. See [the section called “Authentication File Format”](#) for details.

Default: not set

`auth_hba_file`

HBA configuration file to use when `auth_type` is `hba`.

Default: not set

`auth_type`

How to authenticate users.

`pam`

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. PAM is not supported in the HBA configuration file.

`hba`

The actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods for different access paths, for example: connection over Unix socket uses `peer` authentication method, connections over TCP must use TLS.

`cert`

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

`md5`

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

`scram-sha-256`

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

`plain`

The clear-text password is sent over the wire. Deprecated.

`trust`

No authentication is done. The user name must still exist in `auth_file`.

any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

auth\_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

auth\_user

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

pool\_mode

Specifies when a server connection can be reused by other clients.

session

Server is released back to pool after client disconnects. Default.

transaction

Server is released back to pool after transaction finishes.

statement

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

max\_client\_conn

Maximum number of client connections allowed. When increased, the file descriptor limits should also be increased. Note that the actual number of file descriptors used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should be never reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves behavior when usual load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see `reserve_pool_timeout`). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this many seconds, pgbouncer enables use of additional connections from the reserve pool. The 0 value disables this parameter.

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the pgbouncer database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the pgbouncer user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`server_round_robin`

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is TCP round-robin behind a database IP address, then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

`ignore_startup_parameters`

By default, `pgbouncer` allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that `pgbouncer` knows that they are handled by the admin and it can ignore them.

Default: empty

`disable_pgexec`

Disable Simple Query protocol (PQexec). Unlike Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only on start of connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

## Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

`syslog_ident`

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

#### `syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

#### `log_connections`

Log successful logins.

Default: 1

#### `log_disconnections`

Log disconnections with reasons.

Default: 1

#### `log_pooler_errors`

Log error messages the pooler sends to clients.

Default: 1

#### `log_stats`

Write aggregated statistics into the log, every `stats_period`. This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

#### `verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. Using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

### Console Access Control

#### `admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when `auth_type` is `any`, in which case any user name is allowed in as admin.

Default: empty

#### `stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

### Connection Sanity Checks, Timeouts

#### `server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress so it should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL` which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, as clients must not use any session-based features as each transaction ends up in a different connection and thus gets a different session state.

Default: DISCARD ALL

#### `server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

#### `server_check_delay`

How long to keep released connections available for immediate re-use, without running sanity-check queries on it. If 0 then the query is always run.

Default: 30.0

#### `server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: SELECT 1;

#### `server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

#### `server_lifetime`

The pooler will close an unused server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

#### `server_idle_timeout`

If a server connection has been idle more than this many seconds it will be dropped. If 0 then timeout is disabled. [seconds]

Default: 600.0

#### `server_connect_timeout`

If connection and login won't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

#### `server_login_retry`

If login failed, because of failure from `connect()` or authentication that pooler waits this much before retrying to connect. [seconds]

Default: 15.0

#### `client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

#### `autodb_idle_timeout`

If the automatically created (via `"*`) database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

#### `dns_max_ttl`

How long the DNS lookups can be cached. If a DNS lookup returns several answers, pgbouncer will robin-between them in the meantime. The actual DNS TTL is ignored. [seconds]

Default: 15.0

#### `dns_nxdomain_ttl`

How long error and NXDOMAIN DNS lookups can be cached. [seconds]

Default: 15.0

#### `dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, it's connections are invalidated.

Default: 0.0 (disabled)

#### `resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

### **TLS Settings**

#### `client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. TLS connections are disabled by default.

`disable`

Plain TCP. TLS is not even requested from the server. Default.

`prefer`

TLS connection is always requested first from Postgres Pro, when refused connection will be established over plain TCP. Server certificate is not validated.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

### Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

#### `query_timeout`

Queries running longer than that are canceled. This should be used only with slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

#### `query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. This is used to prevent unresponsive servers from grabbing up connections. [seconds]

It also helps when the server is down or database rejects connections for any reason. If this is disabled, clients will be queued indefinitely.

Default: 120

#### `client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

#### `idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

#### `suspend_timeout`

How many seconds to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed.

Default: 10

### Low-Level Network Settings

#### `pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

#### `max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. Full result set can be larger.

Default: 2147483647

#### `listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in queue. When the queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall `pgbouncer` for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple `pgbouncer` instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get `pgbouncer` to use more CPU cores. (`pgbouncer` is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each `pgbouncer` instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific `pgbouncer` instance via TCP/IP, which might have implications for monitoring and metrics collection.

Default: 0

`tcp_defer_accept`

For details on this and other TCP options, please see `man 7 tcp`.

Default: 45 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **`tcp_keepidle=7200`**, **`tcp_keepintvl=75`**, **`tcp_keepcnt=9`**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

### Section [databases]

This contains key=value pairs where key will be taken as a database name and value as a libpq connect-string style list of key=value pairs. As actual libpq is not used, not all features from libpq can be used (service=, .pgpass).

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

\* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to `pgbouncer` specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise `pgbouncer` logs into the destination database with the client user name, meaning that there will be one pool per user.

`password`

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

`auth_user`

Override of the global `auth_user` setting, if specified.

`pool_size`

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

`min_pool_size`

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

`reserve_pool`

Set additional connections for this database. If not set, `reserve_pool_size` is used.

`connect_query`

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

`pool_mode`

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

`max_db_connections`

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

`client_encoding`

Ask specific `client_encoding` from server.

`datestyle`

Ask specific `datestyle` from server.

`timezone`

Ask specific `timezone` from server.

### Section [users]

This contains key=value pairs where the key will be taken as a user name and the value as a libpq connect-string style list of key=value pairs of configuration settings specific for this user. Only a few settings are available here.

`pool_mode`

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

### Include Directive

The pgbouncer configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the file name is not absolute path it is taken as relative to current working directory.

### Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...  
"username2" "md5abcdef012342345" ...  
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

So user admin with password 1234 will have MD5-hashed password  
md545f2603610af569b6155c45067268c6b.

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

### HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 20.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.
- Database field: Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- User name field: Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- Address field: Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- Auth-method field: Only methods supported by pgbouncer's `auth_type` are supported, except any and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

### Example

Minimal config:

```
[databases]  
template1 = host=localhost dbname=template1 auth_user=someuser  
  
[pgbouncer]  
pool_mode = session  
listen_port = 6432
```

```
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

### Database defaults:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

### Example of a secure function for auth\_query:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
  out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END;
$$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

## pg\_filedump

pg\_filedump — display formatted contents of a Postgres Pro heap, index, or control file

### Synopsis

```
pg_filedump [option...] [file]
```

### Description

pg\_filedump is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

### Installation

pg\_filedump is provided with Postgres Pro as a separate pre-built package `pg-filedump-ent-11` (for the detailed installation instructions, see [Chapter 17](#)).

### Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

- `-a`  
Display absolute addresses when formatting. Block header information is always block-relative.
- `-b`  
Display binary block images within a range. The option will turn off all formatting options.
- `-d`  
Display formatted block content dump. The option will turn off all other formatting options.
- `-D attrlist`  
Decode tuples using given comma-separated list of types. The list of supported types:  
  - `bigint`
  - `bigserial`
  - `bool`
  - `char`
  - `charN — char(n)`
  - `date`
  - `float`
  - `float4`
  - `float8`
  - `int`
  - `json`
  - `macaddr`
  - `name`
  - `numeric`
  - `oid`
  - `real`

```

serial
smallint
smallserial
text
time
timestamp
timetz
uuid
varchar
varcharN — varchar(n)
xid
xml
~ — ignore all attributes left in a tuple

```

- f  
Display formatted block content dump along with interpretation.
- h  
Display help.
- i  
Display interpreted item details.
- k  
Verify block checksums.
- o  
Do not dump old values.
- R *startblock* [*endblock*]  
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*  
Force segment size to *segsize*.
- t  
Dump TOAST files.
- v  
Output additional information about TOAST relations.
- n *segnumber*  
Force segment number to *segnumber*.
- S *blocksize*  
Force block size to *blocksize*.
- x  
Force interpreted formatting of block items as index items.
- y  
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

## pgpro\_controldata

pgpro\_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

### Synopsis

```
pgpro_controldata [option...]
```

### Description

pgpro\_controldata prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

pgpro\_controldata also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

### Options

pgpro\_controldata accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like [pg\\_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

#### General-Purpose

`-B`  
`--bindir`  
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`  
`--pgdata=datadir`  
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`  
`--version`  
Print the `pgpro_controldata` version, then exit.

`-?`  
`--help`  
Show help about `pgpro_controldata` command-line arguments, then exit.

#### Compatibility-Related

`-C`  
`--compatibility-check`  
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`  
`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`  
`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

## Environment

`PGDATA`  
Default data directory location

`PG_COLOR`  
Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

## pg\_standby

`pg_standby` — supports the creation of a Postgres Pro warm standby server

### Synopsis

```
pg_standby [option...] archivelocation nextwalfile walfilepath [restartwalfile]
```

### Description

`pg_standby` supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

`pg_standby` is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see [Section 26.2](#)).

To configure a standby server to use `pg_standby`, put this into its `recovery.conf` configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where *archiveDir* is the directory from which WAL segment files should be restored.

If *restartwalfile* is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area.

`pg_standby` assumes that *archivelocation* is a directory readable by the server-owning user. If *restartwalfile* (or `-k`) is specified, the *archivelocation* directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

#### Smart Failover

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

#### Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word `fast` into it. `pg_standby` can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

### Options

`pg_standby` accepts the following command-line arguments:

- `-c`  
Use `cp` or `copy` command to restore WAL files from archive. This is the only supported behavior so this option is useless.
- `-d`  
Print lots of debug logging output on `stderr`.
- `-k`  
Remove files from *archivelocation* so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from *archivelocation*. This

parameter will be silently ignored if *restartwalfile* is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is *deprecated* as of PostgreSQL 8.3; it is safer and more efficient to specify a *restartwalfile* parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

`-r maxretries`

Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for *sleeptime* \* *num\_retries* so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

`-s sleeptime`

Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult [Section 26.2](#) for discussion.

`-t triggerfile`

Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example `/tmp/pgsql.trigger.5432`.

`-V`

`--version`

Print the `pg_standby` version and exit.

`-w maxwaittime`

Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult [Section 26.2](#) for discussion.

`-?`

`--help`

Show help about `pg_standby` command line arguments, and exit.

## Notes

`pg_standby` is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the `%r` macro, which is designed to let `pg_standby` know the last file it needs to keep. With PostgreSQL 8.2, the `-k` option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

PostgreSQL 8.4 provides the `recovery_end_command` option. Without this option a leftover trigger file can be hazardous.

`pg_standby` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

## Examples

On Linux or Unix systems, you might use:

```
archive_command = 'cp %p .../archive/%f'
```

```
restore_command = 'pg_standby -d -s 2 -t /tmp/pgsql.trigger.5442 .../archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'rm -f /tmp/pgsql.trigger.5442'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby (enabling use of `ln`). This will:

- produce debugging output in `standby.log`
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `/tmp/pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

```
archive_command = 'copy %p ...\\archive\\%f'
```

```
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\\archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'del C:\pgsql.trigger.5442'
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command` or `recovery_end_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits *sleep\_time* seconds once it sees the proper file size. GNUWin32's `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

# Appendix H. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

## H.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Enterprise distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. [Table H.1](#) includes a list of some of these projects. Note that some of these packages might not be released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

**Table H.1. Externally Maintained Client Interfaces**

| Name          | Language   | Comments                             | Website                                                                                           |
|---------------|------------|--------------------------------------|---------------------------------------------------------------------------------------------------|
| DBD::Pg       | Perl       | Perl DBI driver                      | <a href="https://metacpan.org/release/DBD-Pg">https://metacpan.org/release/DBD-Pg</a>             |

## H.2. Administration Tools

There are several administration tools available for Postgres Pro. The most popular is [pgAdmin](#), and there are several commercially available ones as well.

## H.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. [Table H.2](#) lists some of these packages. Note that some of these projects might not be released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

**Table H.2. Externally Maintained Procedural Languages**

| Name    | Language   | Website                                                                               |
|---------|------------|---------------------------------------------------------------------------------------|
| PL/Java | Java       | <a href="https://tada.github.io/pljava/">https://tada.github.io/pljava/</a>           |

| PL/R    | R          | <a href="https://github.com/postgres-plr/plr">https://github.com/postgres-plr/plr</a> |
| PL/sh   | Unix shell | <a href="https://github.com/petere/plsh">https://github.com/petere/plsh</a>           |
| PL/v8   | JavaScript | <a href="https://github.com/plv8/plv8">https://github.com/plv8/plv8</a>               |

## H.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in [Appendix F](#). Other extensions are developed independently, like *PostGIS*. Even Postgres Pro replication solutions can be developed externally. For example, *Slony-I* is a popular master/standby replication solution that is developed independently from the core project.

---

# Appendix I. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model.

Make sure that the Russian locale (such as `ru_RU.UTF-8` on Linux systems) is installed and that it is the active locale of the user who creates the database cluster. For example, for Debian systems do the following:

```
sudo dpkg-reconfigure locales # Choose locale ru_RU.UTF-8 to generate
export LANG="ru_RU.UTF-8"
/opt/pgpro/ent-11/bin/pg-setup initdb
```

For more details, see related sections of the documentation for your operating system and for 1C.

Also, for optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

```
max_connections = 1000
```

2. To ensure that temporary tables are handled correctly, modify the following parameters:

- Increase the buffer size for temporary tables:

```
temp_buffers = 32MB
```

- Increase the number of allowed locks of tables or indexes per transaction to 256:

```
max_locks_per_transaction = 256
```

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail, leaving multiple orphaned temporary tables.

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:

```
standard_conforming_strings = off
escape_string_warning = off
```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. Optimize query planning using [plantuner](#) extension, as follows:

- Add `plantuner` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'plantuner'
```

- Tune Postgres Pro optimizer to improve planning for recently created empty tables:

```
plantuner.fix_empty_table = 'on'
```

## Appendix J. Demo Database “Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section J.1](#) for details.

### Figure J.1. Airlines in Russia

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the *PostgreSQL license*.

You can send us your feedback to [edu@postgrespro.ru](mailto:edu@postgrespro.ru).

## J.1. Installation

The demo database is available at [edu.postgrespro.com](https://edu.postgrespro.com) in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user

who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

## J.2. Schema Diagram

**Figure J.2. Bookings Schema Diagram**

## J.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft

model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

## J.4. Schema Objects

### J.4.1. List of Relations

| Name            | Type  | Small | Medium | Big    | Description             |
|-----------------|-------|-------|--------|--------|-------------------------|
| aircrafts       | view  |       |        |        | Aircraft                |
| aircrafts_data  | table | 16 kB | 16 kB  | 16 kB  | Aircraft (translations) |
| airports        | view  |       |        |        | Airports                |
| airports_data   | table | 56 kB | 56 kB  | 56 kB  | Airports (translations) |
| boarding_passes | table | 31 MB | 102 MB | 427 MB | Boarding passes         |
| bookings        | table | 13 MB | 30 MB  | 105 MB | Bookings                |
| flights         | table | 3 MB  | 6 MB   | 19 MB  | Flights                 |
| flights_v       | view  |       |        |        | Flights                 |
| routes          | view  |       |        |        | Routes                  |
| seats           | table | 88 kB | 88 kB  | 88 kB  | Seats                   |
| ticket_flights  | table | 64 MB | 145 MB | 516 MB | Flight segments         |
| tickets         | table | 47 MB | 107 MB | 381 MB | Tickets                 |

### J.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section J.4.15](#) for details.

| Column                     | Type                 | Modifiers             | Description                 |
|----------------------------|----------------------|-----------------------|-----------------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA         |
| <code>model</code>         | <code>text</code>    | <code>not null</code> | Aircraft model              |
| <code>range</code>         | <code>integer</code> | <code>not null</code> | Maximal flying distance, km |

View definition:

```
SELECT ml.aircraft_code,
       ml.model ->> lang() AS model,
       ml.range
FROM aircrafts_data ml;
```

### J.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column                     | Type                 | Modifiers             | Description                 |
|----------------------------|----------------------|-----------------------|-----------------------------|
| <code>aircraft_code</code> | <code>char(3)</code> | <code>not null</code> | Aircraft code, IATA         |
| <code>model</code>         | <code>jsonb</code>   | <code>not null</code> | Aircraft model              |
| <code>range</code>         | <code>integer</code> | <code>not null</code> | Maximal flying distance, km |

Indexes:

```
PRIMARY KEY, btree (aircraft_code)
```

Check constraints:

```
CHECK (range > 0)
```

Referenced by:

```
TABLE "flights" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code)
TABLE "seats" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE
```

#### J.4.4. View `bookings.airports`

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section J.4.15](#) for details.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|
| <code>airport_code</code> | <code>char(3)</code> | <code>not null</code> | Airport code                                 |
| <code>airport_name</code> | <code>text</code>    | <code>not null</code> | Airport name                                 |
| <code>city</code>         | <code>text</code>    | <code>not null</code> | City                                         |
| <code>coordinates</code>  | <code>point</code>   | <code>not null</code> | Airport coordinates (longitude and latitude) |
| <code>timezone</code>     | <code>text</code>    | <code>not null</code> | Airport time zone                            |

FROM airports_data ml;
```

#### J.4.5. Table `bookings.airports_data`

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

| Column                    | Type                 | Modifiers             | Description                                  |
|---------------------------|----------------------|-----------------------|----------------------------------------------|
| <code>airport_code</code> | <code>char(3)</code> | <code>not null</code> | Airport code                                 |

#### J.4.6. Table `bookings.boarding_passes`

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

| Column                   | Type                    | Modifiers             | Description          |
|--------------------------|-------------------------|-----------------------|----------------------|
| <code>ticket_no</code>   | <code>char(13)</code>   | <code>not null</code> | Ticket number        |
| <code>flight_id</code>   | <code>integer</code>    | <code>not null</code> | Flight ID            |
| <code>boarding_no</code> | <code>integer</code>    | <code>not null</code> | Boarding pass number |
| <code>seat_no</code>     | <code>varchar(4)</code> | <code>not null</code> | Seat number          |

Indexes:

```

UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

### J.4.7. Table `bookings.bookings`

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

| Column                    | Type                       | Modifiers             | Description        |
|---------------------------|----------------------------|-----------------------|--------------------|
| <code>book_ref</code>     | <code>char(6)</code>       | <code>not null</code> | Booking number     |
| <code>book_date</code>    | <code>timestamp tz</code>  | <code>not null</code> | Booking date       |
| <code>total_amount</code> | <code>numeric(10,2)</code> | <code>not null</code> | Total booking cost |

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

### J.4.8. Table `bookings.flights`

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (`status`) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

| Column              | Type        | Modifiers | Description              |
|---------------------|-------------|-----------|--------------------------|
| flight_id           | serial      | not null  | Flight ID                |
| flight_no           | char(6)     | not null  | Flight number            |
| scheduled_departure | timestampz  | not null  | Scheduled departure time |
| scheduled_arrival   | timestampz  | not null  | Scheduled arrival time   |
| departure_airport   | char(3)     | not null  | Airport of departure     |
| arrival_airport     | char(3)     | not null  | Airport of arrival       |
| status              | varchar(20) | not null  | Flight status            |
| aircraft_code       | char(3)     | not null  | Aircraft code, IATA      |
| actual_departure    | timestampz  |           | Actual departure time    |
| actual_arrival      | timestampz  |           | Actual arrival time      |

```

## J.4.9. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (seat\_no) and has an assigned travel class (fare\_conditions): Economy, Comfort or Business.

| Column | Type | Modifiers | Description |
|--------|------|-----------|-------------|
|--------|------|-----------|-------------|

```

aircraft_code | char(3)      | not null      | Aircraft code, IATA
seat_no       | varchar(4)   | not null      | Seat number
fare_conditions | varchar(10) | not null      | Travel class

```

Indexes:

```
PRIMARY KEY, btree (aircraft_code, seat_no)
```

Check constraints:

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (aircraft_code)
REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE
```

## J.4.10. Table bookings.ticket\_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (amount) and travel class (fare\_conditions).

| Column          | Type          | Modifiers | Description   |
|-----------------|---------------|-----------|---------------|
| ticket_no       | char(13)      | not null  | Ticket number |
| flight_id       | integer       | not null  | Flight ID     |
| fare_conditions | varchar(10)   | not null  | Travel class  |
| amount          | numeric(10,2) | not null  | Travel cost   |

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
```

Check constraints:

```
CHECK (amount >= 0)
```

```
CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))
```

Foreign-key constraints:

```
FOREIGN KEY (flight_id) REFERENCES flights(flight_id)
```

```
FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

Referenced by:

```
TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

## J.4.11. Table bookings.tickets

A ticket has a unique number (ticket\_no) that consists of 13 digits.

The ticket includes a passenger ID (passenger\_id) — the identity document number, — their first and last names (passenger\_name), and contact information (contact\_data).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

| Column         | Type        | Modifiers | Description                   |
|----------------|-------------|-----------|-------------------------------|
| ticket_no      | char(13)    | not null  | Ticket number                 |
| book_ref       | char(6)     | not null  | Booking number                |
| passenger_id   | varchar(20) | not null  | Passenger ID                  |
| passenger_name | text        | not null  | Passenger name                |
| contact_data   | jsonb       |           | Passenger contact information |

Indexes:

```
PRIMARY KEY, btree (ticket_no)
```

Foreign-key constraints:

```
FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

Referenced by:

```
TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)
```

### J.4.12. View `bookings.flights_v`

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

| Column                                 | Type        | Description                                                       |
|----------------------------------------|-------------|-------------------------------------------------------------------|
| <code>flight_id</code>                 | integer     | Flight ID                                                         |
| <code>flight_no</code>                 | char(6)     | Flight number                                                     |
| <code>scheduled_departure</code>       | timestamptz | Scheduled departure time                                          |
| <code>scheduled_departure_local</code> | timestamp   | Scheduled departure time,<br>local time at the point of departure |
| <code>scheduled_arrival</code>         | timestamptz | Scheduled arrival time                                            |
| <code>scheduled_arrival_local</code>   | timestamp   | Scheduled arrival time,<br>local time at the point of destination |
| <code>scheduled_duration</code>        | interval    | Scheduled flight duration                                         |
| <code>departure_airport</code>         | char(3)     | Departure airport code                                            |
| <code>departure_airport_name</code>    | text        | Departure airport name                                            |
| <code>departure_city</code>            | text        | City of departure                                                 |
| <code>arrival_airport</code>           | char(3)     | Arrival airport code                                              |
| <code>arrival_airport_name</code>      | text        | Arrival airport name                                              |
| <code>arrival_city</code>              | text        | City of arrival                                                   |
| <code>status</code>                    | varchar(20) | Flight status                                                     |
| <code>aircraft_code</code>             | char(3)     | Aircraft code, IATA                                               |
| <code>actual_departure</code>          | timestamptz | Actual departure time                                             |
| <code>actual_departure_local</code>    | timestamp   | Actual departure time,<br>local time at the point of departure    |
| <code>actual_arrival</code>            | timestamptz | Actual arrival time                                               |
| <code>actual_arrival_local</code>      | timestamp   | Actual arrival time,<br>local time at the point of destination    |
| <code>actual_duration</code>           | interval    | Actual flight duration                                            |

### J.4.13. View `bookings.routes`

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

| Column                              | Type    | Description            |
|-------------------------------------|---------|------------------------|
| <code>flight_no</code>              | char(6) | Flight number          |
| <code>departure_airport</code>      | char(3) | Departure airport code |
| <code>departure_airport_name</code> | text    | Departure airport name |
| <code>departure_city</code>         | text    | City of departure      |
| <code>arrival_airport</code>        | char(3) | Arrival airport code   |

|                                   |           |                                                 |
|-----------------------------------|-----------|-------------------------------------------------|
| <code>arrival_airport_name</code> | text      | Arrival airport name                            |
| <code>arrival_city</code>         | text      | City of arrival                                 |
| <code>aircraft_code</code>        | char(3)   | Aircraft code, IATA                             |
| <code>duration</code>             | interval  | Flight duration                                 |
| <code>days_of_week</code>         | integer[] | Days of the week on which flights are performed |

## J.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

## J.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

# J.5. Usage

## J.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

## J.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 19.1](#).

In the examples below, the English language is selected for translatable fields.

## J.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

| aircraft_code | model               | range |
|---------------|---------------------|-------|
| 773           | Boeing 777-300      | 11100 |
| 763           | Boeing 767-300      | 7900  |
| SU9           | Sukhoi SuperJet-100 | 3000  |
| 320           | Airbus A320-200     | 5700  |
| 321           | Airbus A321-200     | 5600  |
| 319           | Airbus A319-100     | 6700  |
| 733           | Boeing 737-300      | 4200  |
| CN1           | Cessna 208 Caravan  | 1200  |
| CR2           | Bombardier CRJ-200  | 2700  |

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

| aircraft_code | model              | seat_no | fare_conditions |
|---------------|--------------------|---------|-----------------|
| CN1           | Cessna 208 Caravan | 1A      | Economy         |
| CN1           | Cessna 208 Caravan | 1B      | Economy         |
| CN1           | Cessna 208 Caravan | 2A      | Economy         |
| CN1           | Cessna 208 Caravan | 2B      | Economy         |
| CN1           | Cessna 208 Caravan | 3A      | Economy         |
| CN1           | Cessna 208 Caravan | 3B      | Economy         |

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT  a.airport_code as code,
        a.airport_name,
        a.city,
        a.coordinates
FROM    airports a
WHERE   a.city IN (
        SELECT  aa.city
        FROM    airports aa
        GROUP BY aa.city
        HAVING  COUNT(*) > 1
        )
ORDER BY a.city, a.airport_code;

```

| code | airport_name           | city      | coordinates                          |
|------|------------------------|-----------|--------------------------------------|

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```

SELECT  r.arrival_city as city,
        r.arrival_airport as code,
        r.arrival_airport_name as airport_name,

```

```

        r.days_of_week,
        r.duration
FROM   routes r
WHERE  r.departure_city = ' Volgograd';

```

| city        | code | airport_name                       | days_of_week    | duration |
|-------------|------|------------------------------------|-----------------|----------|
| Moscow      | SVO  | Sheremetyevo International Airport | {1,2,3,4,5,6,7} | 01:15:00 |
| Chelyabinsk | CEK  | Chelyabinsk Balandino Airport      | {1,2,3,4,5,6,7} | 01:50:00 |
| Rostov      | ROV  | Rostov-on-Don Airport              | {1,2,3,4,5,6,7} | 00:30:00 |
| Moscow      | VKO  | Vnukovo International Airport      | {1,2,3,4,5,6,7} | 01:10:00 |
| Cheboksary  | CSY  | Cheboksary Airport                 | {1,2,3,4,5,6,7} | 02:45:00 |
| Tomsk       | TOF  | Bogashevo Airport                  | {1}             | 03:50:00 |

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

| now                    |
|------------------------|
| 2017-08-15 18:00:00+03 |

In relation to this moment, all flights are classified as past and future flights:

```

SELECT   status,
        count(*) as count,
        min(scheduled_departure) as min_scheduled_departure,
        max(scheduled_departure) as max_scheduled_departure
FROM     flights
GROUP BY status
ORDER BY min_scheduled_departure;

```

| status    | count | min_scheduled_departure | max_scheduled_departure |
|-----------|-------|-------------------------|-------------------------|
| Arrived   | 16707 | 2017-07-16 01:50:00+03  | 2017-08-15 17:25:00+03  |
| Cancelled | 414   | 2017-07-19 11:35:00+03  | 2017-09-14 20:55:00+03  |
| Departed  | 58    | 2017-08-15 09:55:00+03  | 2017-08-15 17:50:00+03  |
| Delayed   | 41    | 2017-08-15 15:15:00+03  | 2017-08-16 17:25:00+03  |
| On Time   | 518   | 2017-08-15 17:55:00+03  | 2017-08-16 18:00:00+03  |
| Scheduled | 15383 | 2017-08-16 18:05:00+03  | 2017-09-14 20:40:00+03  |

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```

\x
SELECT   f.*
FROM     flights_v f
WHERE    f.departure_city = 'Yekaterinburg'
AND      f.arrival_city = 'Moscow'
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT   1;

```

```

-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |

```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

## J.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```

SELECT  *
FROM    bookings
ORDER BY total_amount desc
LIMIT   10;

```

| book_ref | book_date              | total_amount |
|----------|------------------------|--------------|
| 3B54BB   | 2017-07-05 17:08:00+03 | 1204500.00   |
| 3AC131   | 2017-07-31 01:06:00+03 | 1087100.00   |
| 65A6EA   | 2017-07-03 06:28:00+03 | 1065600.00   |
| D7E9AA   | 2017-08-08 05:29:00+03 | 1062800.00   |
| EF479E   | 2017-08-02 15:58:00+03 | 1035100.00   |
| 521C53   | 2017-07-08 09:25:00+03 | 985500.00    |
| 514CA6   | 2017-07-27 05:07:00+03 | 955000.00    |
| D70BD9   | 2017-07-05 12:47:00+03 | 947500.00    |
| EC7EDA   | 2017-07-02 16:13:00+03 | 946800.00    |
| 8E4370   | 2017-07-28 02:04:00+03 | 945700.00    |

(10 rows)

Let's take a look at the tickets included into the booking with code 521C53:

```

SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets

```

```
WHERE book_ref = '521C53';
```

```

ticket_no | passenger_id | passenger_name
-----+-----+-----
0005432661914 | 8234 547529 | IVAN IVANOV
0005432661915 | 2034 201228 | ANTONINA KUZNECOVA
(2 rows)
```

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```

SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        tf.fare_conditions AS class,
        tf.amount
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

```

when | departure | arrival | class | amount
-----+-----+-----+-----+-----
29.07.2017 | Moscow (SVO) | Anadyr (DYR) | Business | 185300.00
02.08.2017 | Anadyr (DYR) | Khabarovsk (KHV) | Business | 92200.00
03.08.2017 | Khabarovsk (KHV) | Blagoveshchensk (BQS) | Business | 18000.00
08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV) | Business | 18000.00
12.08.2017 | Khabarovsk (KHV) | Anadyr (DYR) | Economy | 30700.00
17.08.2017 | Anadyr (DYR) | Moscow (SVO) | Business | 185300.00
(6 rows)
```

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```

SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        f.status,
        bp.seat_no
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
        LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
        AND tf.ticket_no = bp.ticket_no
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

```

when | departure | arrival | status | seat_no
-----+-----+-----+-----+-----
29.07.2017 | Moscow (SVO) | Anadyr (DYR) | Arrived | 5C
02.08.2017 | Anadyr (DYR) | Khabarovsk (KHV) | Arrived | 1D
03.08.2017 | Khabarovsk (KHV) | Blagoveshchensk (BQS) | Arrived | 2C
08.08.2017 | Blagoveshchensk (BQS) | Khabarovsk (KHV) | Arrived | 2D
```

```
12.08.2017 | Khabarovsk (KHV) | Anadyr (DYR) | Arrived | 20B
17.08.2017 | Anadyr (DYR) | Moscow (SVO) | Scheduled |
(6 rows)
```

## J.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 8525, 'Business', 0),
            ('_0000000000001', 4967, 'Business', 0);

COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```
INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 8525, 1, '1A');
```

Now let's check the booking information:

```
SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || ' (' || f.departure_airport || ')' AS departure,
            f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
            AND tf.ticket_no = bp.ticket_no

WHERE      b.book_ref = '_QWE12'
ORDER BY  t.ticket_no, f.scheduled_departure;
```

```
-[ RECORD 1 ]-----+-----
book_ref      | _QWE12
```

|                           |  |                      |
|---------------------------|--|----------------------|
| ticket_no                 |  | _0000000000001       |
| passenger_id              |  | 1749 051790          |
| passenger_name            |  | ALEKSANDR RADISHCHEV |
| fare_conditions           |  | Business             |

# Appendix L. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

## L.1. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg\\_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

## L.2. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg\\_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

## L.3. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg\\_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.

---

# Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department [web site](#).

## SQL Reference Books

- [bowman01] *The Practical SQL Handbook*. Using SQL Variants. Fourth Edition. Judith Bowman, Sandra Emerson, and Marcy Darnovsky. ISBN 0-201-70309-2. Addison-Wesley Professional. 2001.
- [date97] *A Guide to the SQL Standard*. A user's guide to the standard database language SQL. Fourth Edition. C. J. Date and Hugh Darwen. ISBN 0-201-96426-0. Addison-Wesley. 1997.
- [date04] *An Introduction to Database Systems*. Eighth Edition. C. J. Date. ISBN 0-321-19784-4. Addison-Wesley. 2003.
