E.39. Prior Releases

Release notes for prior versions can be found online. At the time of Postgres Pro Enterprise 13 release, these prior versions were supported:

- Postgres Pro Enterprise 12: <https://postgrespro.com/docs/enterprise/12/release.html>
- Postgres Pro Enterprise 11: <https://postgrespro.com/docs/enterprise/11/release.html>
- Postgres Pro Enterprise 10: <https://postgrespro.com/docs/enterprise/10/release.html>
- Postgres Pro Enterprise 9.6: <https://postgrespro.com/docs/enterprise/9.6/release.html>

Appendix F. Additional Supplied Modules

This appendix and the next one contain information regarding additional modules available in the Postgres Pro Enterprise distribution. These include porting tools, analysis utilities, and plug-in features that are not part of the core Postgres Pro system, mainly because they address a limited audience or are too experimental to be part of the main source tree. This does not preclude their usefulness.

This appendix covers the extensions and other server plug-in modules. [Appendix G](#) covers the utility programs.

In Postgres Pro Enterprise, these modules are made available as a separate subpackage `postgrespro-ent-13-contrib`.

Many modules supply new user-defined functions, operators, or types. To make use of one of these modules, after you have installed the code you need to register the new SQL objects in the database system. This is done by executing a `CREATE EXTENSION` command. In a fresh database, you can simply do

```
CREATE EXTENSION module_name;
```

This command registers the new SQL objects in the current database only, so you need to run it in each database that you want the module's facilities to be available in. Alternatively, run it in database `template1` so that the extension will be copied into subsequently-created databases by default.

For all these modules, `CREATE EXTENSION` must be run by a database superuser, unless the module is considered “trusted”, in which case it can be run by any user who has `CREATE` privilege on the current database. Modules that are trusted are identified as such in the sections that follow. Generally, trusted modules are ones that cannot provide access to outside-the-database functionality.

Many modules allow you to install their objects in a schema of your choice. To do that, add `SCHEMA schema_name` to the `CREATE EXTENSION` command. By default, the objects will be placed in your current creation target schema, which in turn defaults to `public`.

Note, however, that some of these modules are not “extensions” in this sense, but are loaded into the server in some other way, for instance by way of [shared_preload_libraries](#). See the documentation of each module for details.

F.1. adminpack

`adminpack` provides a number of support functions which pgAdmin and other administration and management tools can use to provide additional functionality, such as remote management of server log files. Use of all these functions is only allowed to the superuser by default but may be allowed to other users by using the `GRANT` command.

The functions shown in [Table F.1](#) provide write access to files on the machine hosting the server. (See also the functions in [Table 9.95](#), which provide read-only access.) Only files within the database cluster directory can be accessed, unless the user is a superuser or given one of the `pg_read_server_files`, or `pg_write_server_files` roles, as appropriate for the function, but either a relative or absolute path is allowable.

Table F.1. adminpack Functions

Function	Description
<code>pg_catalog.pg_file_write</code>	<code>(filename text, data text, append boolean) → bigint</code> Writes, or appends to, a text file.
<code>pg_catalog.pg_file_sync</code>	<code>(filename text) → void</code>

Function	Description
	Flushes a file or directory to disk.
<code>pg_catalog.pg_file_rename</code> (<i>oldname</i> text, <i>newname</i> text [, <i>archivename</i> text]) → boolean	Renames a file.
<code>pg_catalog.pg_file_unlink</code> (<i>filename</i> text) → boolean	Removes a file.
<code>pg_catalog.pg_logdir_ls</code> () → setof record	Lists the log files in the <code>log_directory</code> directory.

`pg_file_write` writes the specified *data* into the file named by *filename*. If *append* is false, the file must not already exist. If *append* is true, the file can already exist, and will be appended to if so. Returns the number of bytes written.

`pg_file_sync` fsyncs the specified file or directory named by *filename*. An error is thrown on failure (e.g., the specified file is not present). Note that [data_sync_retry](#) has no effect on this function, and therefore a PANIC-level error will not be raised even on failure to flush database files.

`pg_file_rename` renames a file. If *archivename* is omitted or NULL, it simply renames *oldname* to *newname* (which must not already exist). If *archivename* is provided, it first renames *newname* to *archivename* (which must not already exist), and then renames *oldname* to *newname*. In event of failure of the second rename step, it will try to rename *archivename* back to *newname* before reporting the error. Returns true on success, false if the source file(s) are not present or not writable; other cases throw errors.

`pg_file_unlink` removes the specified file. Returns true on success, false if the specified file is not present or the `unlink()` call fails; other cases throw errors.

`pg_logdir_ls` returns the start timestamps and path names of all the log files in the [log_directory](#) directory. The [log_filename](#) parameter must have its default setting (`postgresql-%Y-%m-%d_%H%M%S.log`) to use this function.

F.2. amcheck

The `amcheck` module provides functions that allow you to verify the logical consistency of the structure of relations. If the structure appears to be valid, no error is raised.

The functions verify various *invariants* in the structure of the representation of particular relations. The correctness of the access method functions behind index scans and other important operations relies on these invariants always holding. For example, certain functions verify, among other things, that all B-Tree pages have items in “logical” order (e.g., for B-Tree indexes on `text`, index tuples should be in collated lexical order). If that particular invariant somehow fails to hold, we can expect binary searches on the affected page to incorrectly guide index scans, resulting in wrong answers to SQL queries.

Verification is performed using the same procedures as those used by index scans themselves, which may be user-defined operator class code. For example, B-Tree index verification relies on comparisons made with one or more B-Tree support function 1 routines. See [Section 39.16.3](#) for details of operator class support functions.

`amcheck` functions may only be used by superusers.

F.2.1. Functions

`bt_index_check(index regclass, heapallindexed boolean)` returns void
`bt_index_check(index regclass, heapallindexed boolean, checkunique boolean)` returns void
`bt_index_check` tests that its target, a B-Tree index, respects a variety of invariants. Example usage:

```

test=# SELECT bt_index_check(index => c.oid, heapallindexed => i.indisunique),
           c.relname,
           c.relpages
FROM pg_index i
JOIN pg_opclass op ON i.indclass[0] = op.oid
JOIN pg_am am ON op.opcmethod = am.oid
JOIN pg_class c ON i.indexrelid = c.oid
JOIN pg_namespace n ON c.relnamespace = n.oid
WHERE am.amname = 'btree' AND n.nspname = 'pg_catalog'
-- Don't check temp tables, which may be from another session:
AND c.relpersistence != 't'
-- Function may throw an error when this is omitted:
AND c.relkind = 'i' AND i.indisready AND i.indisvalid
ORDER BY c.relpages DESC LIMIT 10;

```

bt_index_check	relname	relpages
	pg_depend_reference_index	43
	pg_depend_depender_index	40
	pg_proc_proname_args_nsp_index	31
	pg_description_o_c_o_index	21
	pg_attribute_relid_attnam_index	14
	pg_proc_oid_index	10
	pg_attribute_relid_attnum_index	9
	pg_amproc_fam_proc_index	5
	pg_amop_opr_fam_index	5
	pg_amop_fam_strat_index	5

(10 rows)

This example shows a session that performs verification of the 10 largest catalog indexes in the database “test”. Verification of the presence of heap tuples as index tuples is requested for the subset that are unique indexes. Since no error is raised, all indexes tested appear to be logically consistent. Naturally, this query could easily be changed to call `bt_index_check` for every index in the database where verification is supported.

`bt_index_check` acquires an `AccessShareLock` on the target index and the heap relation it belongs to. This lock mode is the same lock mode acquired on relations by simple `SELECT` statements. `bt_index_check` does not verify invariants that span child/parent relationships, but will verify the presence of all heap tuples as index tuples within the index when `heapallindexed` is `true`. `bt_index_check` with three arguments verifies unique constraints when `checkunique` is `true`. When a routine, lightweight test for corruption is required in a live production environment, using `bt_index_check` often provides the best trade-off between thoroughness of verification and limiting the impact on application performance and availability.

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean)` returns void

`bt_index_parent_check(index regclass, heapallindexed boolean, rootdescend boolean, checkunique boolean)` returns void

`bt_index_parent_check` tests that its target, a B-Tree index, respects a variety of invariants. Optionally, when the `heapallindexed` argument is `true`, the function verifies the presence of all heap tuples that should be found within the index. `bt_index_parent_check` with four arguments verifies unique constraints when `checkunique` is `true`. When the optional `rootdescend` argument is `true`, verification re-finds tuples on the leaf level by performing a new search from the root page for each tuple. The checks that can be performed by `bt_index_parent_check` are a superset of the checks that can be performed by `bt_index_check`. `bt_index_parent_check` can be thought of as a more thorough variant of `bt_index_check`: unlike `bt_index_check`, `bt_index_parent_check` also checks invariants that span parent/child relationships, including checking that there are no missing down-links in the index structure. `bt_index_parent_check` follows the general convention of raising an error if it finds a logical inconsistency or other problem.

A `ShareLock` is required on the target index by `bt_index_parent_check` (a `ShareLock` is also acquired on the heap relation). These locks prevent concurrent data modification from `INSERT`, `UPDATE`, and `DELETE` commands. The locks also prevent the underlying relation from being concurrently processed by `VACUUM`, as well as all other utility commands. Note that the function holds locks only while running, not for the entire transaction.

`bt_index_parent_check`'s additional verification is more likely to detect various pathological cases. These cases may involve an incorrectly implemented B-Tree operator class used by the index that is checked, or, hypothetically, undiscovered bugs in the underlying B-Tree index access method code. Note that `bt_index_parent_check` cannot be used when Hot Standby mode is enabled (i.e., on read-only physical replicas), unlike `bt_index_check`.

Tip

`bt_index_check` and `bt_index_parent_check` both output log messages about the verification process at `DEBUG1` and `DEBUG2` severity levels. These messages provide detailed information about the verification process that may be of interest to PostgreSQL developers. Advanced users may also find this information helpful, since it provides additional context should verification actually detect an inconsistency. Running:

```
SET client_min_messages = DEBUG1;
```

in an interactive `psql` session before running a verification query will display messages about the progress of verification with a manageable level of detail.

F.2.2. Optional *heapallindexed* Verification

When the *heapallindexed* argument to verification functions is `true`, an additional phase of verification is performed against the table associated with the target index relation. This consists of a “dummy” `CREATE INDEX` operation, which checks for the presence of all hypothetical new index tuples against a temporary, in-memory summarizing structure (this is built when needed during the basic first phase of verification). The summarizing structure “fingerprints” every tuple found within the target index. The high level principle behind *heapallindexed* verification is that a new index that is equivalent to the existing, target index must only have entries that can be found in the existing structure.

The additional *heapallindexed* phase adds significant overhead: verification will typically take several times longer. However, there is no change to the relation-level locks acquired when *heapallindexed* verification is performed.

The summarizing structure is bound in size by `maintenance_work_mem`. In order to ensure that there is no more than a 2% probability of failure to detect an inconsistency for each heap tuple that should be represented in the index, approximately 2 bytes of memory are needed per tuple. As less memory is made available per tuple, the probability of missing an inconsistency slowly increases. This approach limits the overhead of verification significantly, while only slightly reducing the probability of detecting a problem, especially for installations where verification is treated as a routine maintenance task. Any single absent or malformed tuple has a new opportunity to be detected with each new verification attempt.

F.2.3. Using *amcheck* Effectively

amcheck can be effective at detecting various types of failure modes that [data page checksums](#) will always fail to catch. These include:

- Structural inconsistencies caused by incorrect operator class implementations.

This includes issues caused by the comparison rules of operating system collations changing. Comparisons of datums of a collatable type like `text` must be immutable (just as all comparisons used for B-Tree index scans must be immutable), which implies that operating system collation rules must never change. Though rare, updates to operating system collation rules can cause these issues. More commonly, an inconsistency in the collation order between a master server and a stand-

by server is implicated, possibly because the *major* operating system version in use is inconsistent. Such inconsistencies will generally only arise on standby servers, and so can generally only be detected on standby servers.

If a problem like this arises, it may not affect each individual index that is ordered using an affected collation, simply because *indexed* values might happen to have the same absolute ordering regardless of the behavioral inconsistency. See [Section 23.1](#) and [Section 23.2](#) for further details about how Postgres Pro uses operating system locales and collations.

- Structural inconsistencies between indexes and the heap relations that are indexed (when *heapallindexed* verification is performed).

There is no cross-checking of indexes against their heap relation during normal operation. Symptoms of heap corruption can be subtle.

- Corruption caused by hypothetical undiscovered bugs in the underlying Postgres Pro access method code, sort code, or transaction management code.

Automatic verification of the structural integrity of indexes plays a role in the general testing of new or proposed Postgres Pro features that could plausibly allow a logical inconsistency to be introduced. Verification of table structure and associated visibility and transaction status information plays a similar role. One obvious testing strategy is to call `amcheck` functions continuously when running the standard regression tests.

- File system or storage subsystem faults where checksums happen to simply not be enabled.

Note that `amcheck` examines a page as represented in some shared memory buffer at the time of verification if there is only a shared buffer hit when accessing the block. Consequently, `amcheck` does not necessarily examine data read from the file system at the time of verification. Note that when checksums are enabled, `amcheck` may raise an error due to a checksum failure when a corrupt block is read into a buffer.

- Corruption caused by faulty RAM, or the broader memory subsystem.

Postgres Pro does not protect against correctable memory errors and it is assumed you will operate using RAM that uses industry standard Error Correcting Codes (ECC) or better protection. However, ECC memory is typically only immune to single-bit errors, and should not be assumed to provide *absolute* protection against failures that result in memory corruption.

When *heapallindexed* verification is performed, there is generally a greatly increased chance of detecting single-bit errors, since strict binary equality is tested, and the indexed attributes within the heap are tested.

In general, `amcheck` can only prove the presence of corruption; it cannot prove its absence.

F.2.4. Repairing Corruption

No error concerning corruption raised by `amcheck` should ever be a false positive. `amcheck` raises errors in the event of conditions that, by definition, should never happen, and so careful analysis of `amcheck` errors is often required.

There is no general method of repairing problems that `amcheck` detects. An explanation for the root cause of an invariant violation should be sought. `pageinspect` may play a useful role in diagnosing corruption that `amcheck` detects. A `REINDEX` may not be effective in repairing corruption.

F.3. aqo

The `aqo` module is a Postgres Pro Enterprise extension for cost-based query optimization. Using machine learning methods, more precisely, a modification of the k-NN algorithm, `aqo` improves cardinality estimation, which can optimize execution plans and, consequently, speed up query execution.

The `aqo` module can collect statistics on all the executed queries, excluding the queries that access system relations. The collected statistics is classified by query class. If the queries differ in their constants

only, they belong to the same class. For each query class, aqo stores the cardinality quality, planning time, execution time, and execution statistics for machine learning. Based on this data, aqo builds a new query plan and uses it for the next query of the same class. aqo test runs have shown significant performance improvements for complex queries.

Important

Query optimization using the aqo module is not supported on standby.

aqo saves all the learning data ([aqo_data](#)), queries ([aqo_query_texts](#)), query settings ([aqo_queries](#)), and query execution statistics ([aqo_query_stat](#)) to files. When aqo starts, it loads this data to shared memory. You can access aqo data through functions and views.

Warning

Be aware that aqo may not work correctly right after extension upgrades that change its kernel and after Postgres Pro upgrades. Therefore, after each Postgres Pro upgrade, call `aqo_reset()` and run `DROP EXTENSION aqo`. However, after Postgres Pro minor release upgrades to versions to 13.11/14.8/15.3 or higher a call to `aqo_reset()` is not needed as aqo is reset automatically if required.

After a minor release upgrade, also run `ALTER EXTENSION aqo UPDATE` and keep in mind that aqo downgrade is impossible.

In the event of an automatic aqo reset or manually calling `aqo_reset()`, all the machine learning data gets lost, and new learning will be needed for future aqo use. Therefore, if some data, such as query texts, may help in aqo learning, back up this data in advance.

F.3.1. Installation and Setup

The aqo extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable aqo:

1. Add aqo to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'aqo'
```

The aqo library must be preloaded at the server startup, since adaptive query optimization needs to be enabled per cluster.

2. Create the aqo extension using the following query:

```
CREATE EXTENSION aqo;
```

Once the extension is created, you can start optimizing queries.

The command

```
DROP EXTENSION aqo;
```

will only remove aqo interface at the cluster level. aqo will still be running on all the backends while it is listed in `shared_preload_libraries` and at the server restart, will continue working in the operation mode specified in `postgresql.conf`. Besides, aqo will retain its internal state after consequent execution of `DROP EXTENSION -> CREATE EXTENSION`.

To remove all the data from the aqo storage, including the collected statistics, call `aqo_reset()`:

```
SELECT aqo_reset();
```

To actually disable aqo at the cluster level, do the following:

```
ALTER SYSTEM SET aqo.mode = 'disabled';
```

```
SELECT pg_reload_conf();  
DROP EXTENSION aqo;
```

If you do not want aqo to be loaded at the server restart, remove the line

```
shared_preload_libraries = 'aqo'
```

from the `postgresql.conf` file.

F.3.1.1. Configuration

With the default operation mode (`controlled`), aqo does not affect query performance. Depending on your database usage model, you should choose between the following modes:

- `intelligent` — this mode auto-tunes your queries based on statistics collected per query class. See the description of the `auto_tuning` flag of the [aqo_queries](#) view for more details.
- `forced` — this mode collects statistics for all queries altogether without any classification.
- `controlled` — this mode uses the default planner for all new queries, but continues using the previously specified planning settings for already known query classes, if any.
- `learn` — this mode collects statistics on all the executed queries and updates the data for query classes without auto-tuning queries.
- `frozen` — this mode reads the collected statistics for already known query classes but does not collect any new data. You can use this mode to reduce the impact of aqo on query planning and execution.
- `disabled` — this mode disables aqo for all queries, even for the known query classes. The collected statistics and aqo settings are saved and can be used in the future. You can use this mode to temporarily disable aqo without losing the collected statistics and configuration.

To dynamically change the aqo mode in your current session, run the following command:

```
ALTER SYSTEM SET aqo.mode = 'mode';  
SELECT pg_reload_conf();
```

where `mode` is the name of the operation mode to use.

F.3.2. Usage

F.3.2.1. Choosing Operation Mode for Query Optimization

If you often run queries of the same class, for example, your application limits the number of possible query classes, you can use the `intelligent` mode to improve planning for these queries. In this mode, aqo analyzes each query execution and stores statistics. Statistics on queries of different classes is stored separately. If performance is not improved after 50 iterations, the aqo extension falls back to the default query planner.

Note

You can view the current query plan using the standard Postgres Pro `EXPLAIN` command with the `ANALYZE` option. For details, see the [Section 14.1](#).

Since the `intelligent` mode tries to learn separately for different query classes, aqo may fail to provide performance improvements if queries in the workload are of multiple different classes or if the classes of the queries in the workload are constantly changing. For such workloads, reset the aqo extension to the `controlled` mode, or try using the `forced` mode.

In the `forced` mode, aqo does not classify the collected statistics by query classes and tries to optimize all queries together. Therefore, [aqo_query_texts](#), [aqo_queries](#) and [aqo_query_stat](#) views do not get updated. Machine learning data collected in any other modes is inapplicable for the `forced` mode and vice versa. This mode can help you optimize workloads with multiple different query classes, and it consumes less memory than the `intelligent` mode. However, since the `forced` mode lacks intelligent tuning, performance may decrease for some queries. If you see performance issues in this mode, switch aqo to the `controlled` mode.

In the `controlled` mode, aqo does not collect statistics for new query classes, so they will not be optimized. For known query classes, aqo will continue collecting statistics and using optimized planning algorithms. So use the `controlled` mode only after aqo learned in the `learn` or `intelligent` mode. As there are no query classes in the `forced` mode, switching from it to the `controlled` mode actually means disabling aqo.

The `learn` mode collects statistics from all the executed queries and updates the data for query classes. This mode is similar to the `intelligent` mode, except that it does not provide intelligent tuning.

If you want to reduce the impact of aqo on query planning and execution, you can use it in the `frozen` mode. In this mode, aqo only reads the collected statistics for already known query classes but does not collect any new data.

Switching to the `disabled` mode is the only way to actually disable aqo without losing the statistics and aqo settings, which are saved and can be used in the future. Queries in this mode will be executed as though there were no aqo at all.

F.3.2.2. Fine-Tuning aqo

You must have superuser rights to access aqo views and configure advanced query settings.

When run in the `intelligent` or `learn` mode, aqo assigns a unique hash value to each query class to separate the collected statistics. If you switch to the `forced` mode, the statistics for all untracked query classes is stored in a common query class with hash 0. You can view all the processed query classes and their corresponding hash values in the `aqo_query_texts` view:

```
SELECT * FROM aqo_query_texts;
```

To find out the class, that is, hash, of a query and aqo mode, enable `aqo.show_hash` and `aqo.show_details` environment variables and execute the query. The output will contain something like this:

```
...
Planning Time: 23.538 ms
...
Execution Time: 249813.875 ms
...
Using aqo: true
...
AQO mode: LEARN
...
Query hash: -2439501042637610315
```

Each query class has an associated separate space, called *feature space*, in which the statistics for this query class is collected. Each feature space has associated *feature subspaces*, where the information about selectivity and cardinality for each query plan node is collected.

Each query class has its own optimization settings. These settings are shown in the `aqo_queries` view:

```
SELECT * FROM aqo_queries;
```

The settings available are listed in the [aqo_queries View](#) table.

You can manually change these settings to adjust optimization for a particular query class. For example:

```
-- Add a new query class into the aqo_queries view:

SET aqo.mode='intelligent';
SELECT * FROM a, b WHERE a.id=b.id;
SET aqo.mode='controlled';

-- Disable auto_tuning, enable both learn_aqo and use_aqo
-- for this query class:
```

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,  
  LATERAL aqo_queries_update(q1.queryid, NULL, true, true, false) AS q2  
WHERE queryid = (SELECT queryid FROM aqo_query_texts  
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

-- Run EXPLAIN ANALYZE until the plan changes:

```
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;  
EXPLAIN ANALYZE SELECT * FROM a, b WHERE a.id=b.id;
```

-- Disable learning to stop statistics collection
-- and use the optimized plan:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,  
  LATERAL aqo_queries_update(q1.queryid, NULL, false, true, false) AS q2  
WHERE queryid = (SELECT queryid FROM aqo_query_texts  
WHERE query_text LIKE 'SELECT * FROM a, b WHERE a.id=b.id;');
```

To stop intelligent tuning for a particular query class, disable the `auto_tuning` setting:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,  
  LATERAL aqo_queries_update(q1.queryid, NULL, true, true, false) AS q2  
WHERE queryid = 'hash');
```

where *hash* is the hash value for this query class. As a result, aqo disables automatic change of the `learn_aqo` and `use_aqo` settings.

To disable further learning for a particular query class, use the following command:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,  
  LATERAL aqo_queries_update(q1.queryid, NULL, false, true, false) AS q2  
WHERE queryid = 'hash');
```

where *hash* is the hash value for this query class.

To fully disable aqo for all queries and use the default Postgres Pro query planner, run:

```
SELECT count(*) FROM (SELECT queryid FROM aqo_queries) AS q1,  
  LATERAL aqo_queries_update(q1.queryid, NULL, false, false, false) AS q2  
WHERE queryid IN (SELECT queryid FROM aqo_query_texts);
```

F.3.3. Reference

F.3.3.1. Configuration Parameters

`aqo.mode` (text)

Defines the aqo operation mode. Possible values are listed in [Section F.3.1.1](#).

Default: `controlled`.

`aqo.show_hash` (boolean)

Show a hash value that is computed from a query tree and uniquely identifies the class of queries or class of plan nodes. Starting with Postgres Pro 14, aqo uses the native query ID to identify a query class for consistency with other extensions, such as [pg_stat_statements](#). So, the query ID can be taken from the `Query Identifier` field in `EXPLAIN ANALYZE` output of a query.

Default: `off`.

`aqo.show_details` (boolean)

Add some details to `EXPLAIN` output of a query, such as the prediction or feature-subspace hash, and show some additional aqo-specific on-screen information.

Default: `off`.

`aqo.join_threshold (integer)`

Ignore queries that contain smaller number of joins, which means that statistics for such queries will not be collected.

Default: 3.

`aqo.statement_timeout (integer)`

Defines the initial value of the *smart statement timeout*, in milliseconds, which is needed to limit the execution time when manually training aqo on special queries with a poor cardinality forecast. aqo can dynamically change the value of the smart statement timeout during this training. When the cardinality estimation error on nodes exceeds 0.1, the value of `aqo.statement_timeout` is automatically incremented exponentially, but remains not greater than [statement_timeout](#).

Default: 0.

`aqo.force_collect_stat (boolean)`

Gather statistics on query executions even in the `disabled` mode. Although no predictions are made, some overhead will be added.

Default: `off`.

`aqo.dsm_size_max (integer)`

Defines the maximum size of dynamic shared memory, in MB, that aqo can allocate to store learning data. When this number is exceeded, an attempt to load the [aqo_data](#) view will fail with “out of memory” error.

Default: 100.

`aqo.fs_max_items (integer)`

Defines the maximum number of feature spaces that aqo can operate with. When this number is exceeded, learning on new query classes will no longer occur, and they will not appear in the views accordingly.

Default: 10000.

`aqo.fss_max_items (integer)`

Defines the maximum number of feature subspaces that aqo can operate with. When this number is exceeded, the selectivity and cardinality for new query plan nodes will no longer be collected, and new feature subspaces will not appear in the [aqo_data](#) view accordingly.

Default: 100000.

`aqo.wide_search (boolean)`

Enables searching neighbors with the same feature subspace among different query classes.

Default: `off`.

`aqo.querytext_max_size (integer)`

Defines the maximum size of the query in the [aqo_query_texts](#) view.

Default: 1000.

`aqo.min_neighbors_for_predicting (integer)`

Defines the minimum number of neighbors needed for the cardinality prediction. If there are fewer of them, aqo will not make any prediction.

Default: 3.

`aqo.predict_with_few_neighbors (boolean)`

Enables aqo to make predictions with fewer neighbors than were found.

Default: on.

F.3.3.2. Views

F.3.3.2.1. `aqo_query_texts`

The `aqo_query_texts` view classifies all the query classes processed by aqo. For each query class, the view shows the text of the first analyzed query of this class.

Table F.2. `aqo_query_texts` View

Column Name	Description
<code>queryid</code>	Stores the query ID, that is, the feature-space hash, that uniquely identifies the query class.
<code>query_text</code>	Provides the text of the first analyzed query of the given class.

F.3.3.2.2. `aqo_queries`

The `aqo_queries` view shows optimization settings for different query classes.

Table F.3. `aqo_queries` View

Setting	Description
<code>queryid</code>	Stores the query ID that uniquely identifies the query class.
<code>learn_aqo</code>	Enables statistics collection for this query class.
<code>use_aqo</code>	Enables the aqo cardinality prediction for the next execution of this query class. If the cost estimation model is inaccurate, this may slow down query execution.
<code>fspace_hash</code>	Provides a unique identifier of the separate space in which the statistics for this query class is collected. By default, <code>fspace_hash</code> is equal to <code>queryid</code> . You can change this setting to a different <code>queryid</code> to optimize different query classes together. It may decrease the amount of memory for models and even improve query execution performance. However, changing this setting may cause unexpected aqo behavior, so make sure to use it only if you know what you are doing.
<code>auto_tuning</code>	Shows whether aqo can dynamically change <code>use_aqo</code> and <code>learn_aqo</code> settings for this query class. By default, auto-tuning is only enabled in the intelligent mode. In more detail, when <code>auto_tuning</code> is on, if for several successive executions of a query for which <code>use_aqo</code> is off, the cardinality error remains sufficiently small and stable, aqo turns on <code>use_aqo</code>. For queries with <code>learn_aqo = true</code> (it is so for new queries), several first executions are done both using aqo and without it. The faster the query is executed compared to the execution with the standard planner, the more likely aqo will be used for the next query execution. If after a certain number of executions the execution time with

Setting	Description
	aqo appears to be worse than with the standard planner, aqo will never be used for this query class: <code>auto_tuning</code> , <code>use_aqo</code> and <code>learn_aqo</code> are set to <code>off</code> .
<code>smart_timeout</code>	Shows the value of smart statement timeout for this query class.
<code>count_increase_timeout</code>	Shows how many times the smart statement timeout increased for this query class.

F.3.3.2.3. aqo_data

The `aqo_data` view shows machine learning data for cardinality estimation refinement. To forget all the collected statistics for a particular query class, you can delete all rows from `aqo_data` with the corresponding `fs`.

Table F.4. aqo_data View

Data	Description
<code>fs</code>	Feature-space hash.
<code>fss</code>	Feature-subspace hash.
<code>nfeatures</code>	Feature-subspace size for the query plan node.
<code>features</code>	Logarithm of the selectivity which the cardinality prediction is based on.
<code>targets</code>	Cardinality logarithm for the query plan node.
<code>reliability</code>	Equals: • 1 — indicates data obtained after normal execution of a query • 0.1 — indicates data obtained from a partially executed node (not needed as unreliable) • 0.9 — indicates data obtained from a finished node, but from a partially executed statement
<code>oids</code>	List of IDs of tables that were involved in the prediction for this node.

F.3.3.2.4. aqo_query_stat

The `aqo_query_stat` view shows statistics on query execution, by query class. The aqo extension uses this data when the `auto_tuning` option is enabled for a particular query class.

Table F.5. aqo_query_stat View

Data	Description
<code>execution_time_with_aqo</code>	Execution time for queries run with aqo enabled.
<code>execution_time_without_aqo</code>	Execution time for queries run with aqo disabled.
<code>planning_time_with_aqo</code>	Planning time for queries run with aqo enabled.
<code>planning_time_without_aqo</code>	Planning time for queries run with aqo disabled.
<code>cardinality_error_with_aqo</code>	Cardinality estimation error in the selected query plans with aqo enabled.
<code>cardinality_error_without_aqo</code>	Cardinality estimation error in the selected query plans with aqo disabled.
<code>executions_with_aqo</code>	Number of queries run with aqo enabled.

Data	Description
<code>executions_without_aqo</code>	Number of queries run with aqo disabled.

F.3.3.3. Functions

aqo adds several functions to Postgres Pro catalog.

F.3.3.3.1. Storage Management Functions

Important

Functions `aqo_queries_update`, `aqo_query_texts_update`, `aqo_query_stat_update`, and `aqo_data_update` modify data files underlying aqo views. Therefore, call these functions only if you understand the logic of adaptive query optimization.

`aqo_cleanup()` → `setof integer`

Removes data related to query classes that are linked (may be partially) with removed relations. Returns the number of removed feature spaces (classes) and feature subspaces. Insensitive to removing other objects.

`aqo_enable_class(queryid bigint)` → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the intelligent mode) to true for a given query class.

`aqo_disable_class(queryid bigint)` → `void`

Sets `learn_aqo`, `use_aqo` and `auto_tuning` (only in the intelligent mode) to false for a given query class.

`aqo_drop_class(queryid bigint)` → `integer`

Removes all data related to a given query class from the aqo storage. Returns the number of records removed from the aqo storage.

`aqo_reset()` → `bigint`

Removes data from the aqo storage: machine learning data, query texts, statistics and query class preferences. Returns the number of records removed from the aqo storage.

`aqo_queries_update(queryid bigint, fs bigint, learn_aqo boolean, use_aqo boolean, auto_tuning boolean)` → `boolean`

Assigns new values to the following settings in the [aqo_queries](#) view for a given query class: `fspace_hash`, `learn_aqo`, `use_aqo` and `auto_tuning`. NULL value means “leave as is”.

`aqo_query_texts_update(queryid bigint, query_text text)` → `boolean`

Updates or inserts a record in a data file underlying the [aqo_query_texts](#) view for a given `queryid`.

`aqo_query_stat_update(queryid bigint, execution_time_with_aqo double precision[], execution_time_without_aqo double precision[], planning_time_with_aqo double precision[], planning_time_without_aqo double precision[], cardinality_error_with_aqo double precision[], cardinality_error_without_aqo double precision[], executions_with_aqo bigint[], executions_without_aqo bigint[])` → `boolean`

Updates or inserts a record in a data file underlying the [aqo_query_stat](#) view for a given `queryid`.

`aqo_data_update(fs bigint, fss integer, nfeatures integer, features double precision[][], targets double precision[], reliability double precision[], oids oid[])` → `boolean`

Updates or inserts a record in a data file underlying the [aqo_data](#) view for given `fs` and `fss`.

F.3.3.3.2. Memory Management Functions

`aqo_memory_usage () → setof record`

Displays sizes of aqo memory contexts and hash tables.

F.3.3.3.3. Analytics Functions

`aqo_cardinality_error (controlled boolean) → setof record`

Shows the cardinality error for each query class. If *controlled* is true, shows the error of the last execution with aqo enabled. If *controlled* is false, returns the average cardinality error for all logged executions with aqo disabled.

`aqo_execution_time (controlled boolean) → setof record`

Shows the execution time for each query class. If *controlled* is true, shows the execution time of the last execution with aqo enabled. If *controlled* is false, returns the average execution time for all logged executions with aqo disabled.

F.3.4. Examples

Example F.1. Learning on a Query

Consider optimization of a query using aqo.

When the query is executed for the first time, it is missing in tables underlying aqo views. So there is no data for predicting with aqo for each plan node, and “AQO not used” lines appear in the EXPLAIN output:

```
postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score join
course on score.cno=course.cno join student on score.sno=student.sno where degree<90
and test_preparation = 0;

                                QUERY PLAN
-----
Aggregate  (cost=308.28..308.29 rows=1 width=8) (actual rows=1 loops=1)
  AQO not used, fss=0
  -> Hash Join  (cost=124.80..299.47 rows=3526 width=0) (actual rows=3649 loops=1)
    AQO not used, fss=2128507884
    Hash Cond: (score.sno = student.sno)
    -> Hash Join  (cost=16.30..181.70 rows=3526 width=4) (actual rows=3649
loops=1)
      AQO not used, fss=-303037802
      Hash Cond: (score.cno = course.cno)
      -> Seq Scan on score  (cost=0.00..156.00 rows=3526 width=8) (actual
rows=3649 loops=1)
        AQO not used, fss=-636613046
        Filter: ((degree < 90) AND (test_preparation = 0))
        Rows Removed by Filter: 1351
      -> Hash  (cost=12.80..12.80 rows=280 width=4) (actual rows=10 loops=1)
        Buckets: 1024  Batches: 1  Memory Usage: 9kB
        -> Seq Scan on course  (cost=0.00..12.80 rows=280 width=4)
(actual rows=10 loops=1)
          AQO not used, fss=-1076069505
        -> Hash  (cost=71.00..71.00 rows=3000 width=4) (actual rows=3000 loops=1)
          Buckets: 4096  Batches: 1  Memory Usage: 138kB
          -> Seq Scan on student  (cost=0.00..71.00 rows=3000 width=4) (actual
rows=3000 loops=1)
            AQO not used, fss=-1838231581

Using aqo: true
AQO mode: LEARN
Query hash: -727505571757520766
```

JOINS: 2
(24 rows)

If there is no information on a certain node in the `aqo_data` view, aqo will add the appropriate record there for future learning and predictions except for nodes with `fss=0` in the `EXPLAIN` output. As each of features and targets in the `aqo_data` view is a logarithm to base e , to get the actual value, raise e to this power. For example: `exp(0)`:

fs features oids	fss	nfeatures	targets	reliability
-727505571757520766	2128507884	4	{-0.03438753143452488,-5.634789603169249,-0.3149847743198556,-8.006367567650246}}	{1}
{8.202208436436448}	{1}	{16579,16555,16563}		
-727505571757520766	-1076069505	0	{2.302585092994046}	{1}
{16555}				
-727505571757520766	-1838231581	0	{8.006367567650246}	{1}
{16563}				
-727505571757520766	-303037802	3	{-0.03438753143452488,-5.634789603169249,-0.3149847743198556}}	
{8.202208436436448}	{1}	{16579,16555}		
-727505571757520766	-636613046	2	{-0.03438753143452488,-0.3149847743198556}}	
{8.202208436436448}	{1}	{16579}		

(6 rows)

When the query is executed for the second time, aqo recognizes the query and makes a prediction. Pay attention to the cardinality predicted by aqo and the value of aqo error ("error=0%").

```
postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score join
course on score.cno=course.cno join student on score.sno=student.sno where degree<90
and test_preparation = 0;
```

QUERY PLAN

```
Aggregate (cost=305.86..305.87 rows=1 width=8) (actual rows=1 loops=1)
  AQO not used, fss=0
    -> Hash Join (cost=121.42..296.74 rows=3649 width=0) (actual rows=3649 loops=1)
      AQO: rows=3649, error=0%, fss=2128507884
      Hash Cond: (score.sno = student.sno)
        -> Hash Join (cost=12.93..178.65 rows=3649 width=4) (actual rows=3649
loops=1)
          AQO: rows=3649, error=0%, fss=-303037802
          Hash Cond: (score.cno = course.cno)
            -> Seq Scan on score (cost=0.00..156.00 rows=3649 width=8) (actual
rows=3649 loops=1)
              AQO: rows=3649, error=0%, fss=-636613046
              Filter: ((degree < 90) AND (test_preparation = 0))
              Rows Removed by Filter: 1351
            -> Hash (cost=12.80..12.80 rows=10 width=4) (actual rows=10 loops=1)
              Buckets: 1024 Batches: 1 Memory Usage: 9kB
              -> Seq Scan on course (cost=0.00..12.80 rows=10 width=4) (actual
rows=10 loops=1)
                AQO: rows=10, error=0%, fss=-1076069505
          -> Hash (cost=71.00..71.00 rows=3000 width=4) (actual rows=3000 loops=1)
```

```

Buckets: 4096  Batches: 1  Memory Usage: 138kB
-> Seq Scan on student  (cost=0.00..71.00 rows=3000 width=4) (actual

-727505571757520766	-636613046	2	{-0.03438753143452488,-0.3149847743198556}}	{1}
{8.202208436436448}	{1}	{16579}		

(6 rows)

Let's change a constant in the query, and you will notice that the prediction is made with an error:

```

postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score
join course on score.cno=course.cno join student on score.sno=student.sno where
degree<80 and test_preparation = 0;

```

QUERY PLAN

```

Aggregate  (cost=305.86..305.87 rows=1 width=8) (actual rows=1 loops=1)
  AQO not used, fss=0
    -> Hash Join  (cost=121.42..296.74 rows=3649 width=0) (actual rows=3551 loops=1)
          AQO: rows=3649, error=3%, fss=2128507884
          Hash Cond: (score.sno = student.sno)
            -> Hash Join  (cost=12.93..178.65 rows=3649 width=4) (actual rows=3551
loops=1)
                  AQO: rows=3649, error=3%, fss=-303037802
                  Hash Cond: (score.cno = course.cno)
                    -> Seq Scan on score  (cost=0.00..156.00 rows=3649 width=8) (actual
rows=3551 loops=1)
                          AQO: rows=3649, error=3%, fss=-636613046
                          Filter: ((degree < 80) AND (test_preparation = 0))
                          Rows Removed by Filter: 1449
                    -> Hash  (cost=12.80..12.80 rows=10 width=4) (actual rows=10 loops=1)
                          Buckets: 1024  Batches: 1  Memory Usage: 9kB

```

```

-> Seq Scan on course (cost=0.00..12.80 rows=10 width=4) (actual
rows=10 loops=1)
      AQP: rows=10, error=0%, fss=-1076069505
-> Hash (cost=71.00..71.00 rows=3000 width=4) (actual rows=3000 loops=1)
      Buckets: 4096 Batches: 1 Memory Usage: 138kB
-> Seq Scan on student (cost=0.00..71.00 rows=3000 width=4) (actual
rows=3000 loops=1)
      AQP: rows=3000, error=0%, fss=-1838231581
Using aqo: true
AQO mode: LEARN
Query hash: -727505571757520766
JOINS: 2
(24 rows)

```

However, instead of recalculating features and targets, aqo added new values of selectivity and cardinality for this query to aqo_data:

fs	fss	nfeatures	features	targets
reliability	oids			
-727505571757520766	1141621836	0	{0}	{1}
-727505571757520766	2128507884	4	{-0.030949078292235133,-5.634789603169249,-0.3149847743198556,-8.006367567650246},	
-727505571757520766	-1076069505	0	{8.202208436436448,8.174984532943087}	{16579,16555,16563}
-727505571757520766	-1838231581	0	{2.302585092994046}	{1}
-727505571757520766	-303037802	3	{-0.030949078292235133,-5.634789603169249,-0.3149847743198556},	
-727505571757520766	-636613046	2	{-0.030949078292235133,-0.3149847743198556},	{16579,16555}

Now the prediction has no error:

```

postgres=# EXPLAIN (ANALYZE, SUMMARY OFF, TIMING OFF) select count(*) from score join
course on score.cno=course.cno join student on score.sno=student.sno where degree<80
and test_preparation = 0;

```

QUERY PLAN

```

Aggregate (cost=305.10..305.11 rows=1 width=8) (actual rows=1 loops=1)
  AQP not used, fss=0

Example F.2. Using the [aqo_query_stat](#) View

The `aqo_query_stats` view shows statistics on the query planning time, query execution time and cardinality error. Based on this data you can make a decision whether to use aqo predictions for different query classes.

Let's query the `aqo_query_stats` view:

```

select queryid, cardinality_error_with_aqo,
       cardinality_error_without_aqo, execution_time_with_aqo, execution_time_without_aqo,
       planning_time_with_aqo, planning_time_without_aqo from aqo_query_stat \gx
-[ RECORD 1 ]-----
+-----+-----+-----+-----+-----+-----+
queryid          | 8041624334006338922
cardinality_error_with_aqo |
{0.14932737556062836,0,0.507421202801325,0.00040469447777891077}
cardinality_error_without_aqo | {0.1493979460962751,0.018403615483185476}
execution_time_with_aqo      | {0.004760108,0.008743075,0.006608304,0.012392751}
execution_time_without_aqo   | {0.005775926,0.012730316}
planning_time_with_aqo       | {0.006927997,0.004247339,0.005005022,0.004169717}
planning_time_without_aqo    | {0.001783542,0.001706121}

```

The retrieved data is for the query from [Example F.1](#), which was executed once without aqo for each of the parameters `degree<80` and `degree<90` and twice with aqo for each of these parameters. It is clear that with aqo, the cardinality error decreases to 0.0004, while the minimum cardinality error without aqo is 0.15. Besides, the execution time with aqo is lower than without it. So the conclusion is that aqo learns well on this query, and the prediction can be used for this query class.

F.3.5. Author

Oleg Ivanov

F.4. `auth_delay`

`auth_delay` causes the server to pause briefly before reporting authentication failure, to make brute-force attacks on database passwords more difficult. Note that it does nothing to prevent denial-of-service attacks, and may even exacerbate them, since processes that are waiting before reporting authentication failure will still consume connection slots.

In order to function, this module must be loaded via [shared_preload_libraries](#) in `postgresql.conf`.

F.4.1. Configuration Parameters

`auth_delay.milliseconds (int)`

The number of milliseconds to wait before reporting an authentication failure. The default is 0.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'auth_delay'

auth_delay.milliseconds = '500'
```

F.4.2. Author

KaiGai Kohei <kaigai@ak.jp.nec.com>

F.5. auto_explain

The `auto_explain` module provides a means for logging execution plans of slow statements automatically, without having to run [EXPLAIN](#) by hand. This is especially helpful for tracking down un-optimized queries in large applications.

The module provides no SQL-accessible functions. To use it, simply load it into the server. You can load it into an individual session:

```
LOAD 'auto_explain';
```

(You must be superuser to do that.) More typical usage is to preload it into some or all sessions by including `auto_explain` in [session_preload_libraries](#) or [shared_preload_libraries](#) in `postgresql.conf`. Then you can track unexpectedly slow queries no matter when they happen. Of course there is a price in overhead for that.

F.5.1. Configuration Parameters

There are several configuration parameters that control the behavior of `auto_explain`. Note that the default behavior is to do nothing, so you must set at least `auto_explain.log_min_duration` if you want any results.

`auto_explain.log_min_duration (integer)`

`auto_explain.log_min_duration` is the minimum statement execution time, in milliseconds, that will cause the statement's plan to be logged. Setting this to 0 logs all plans. -1 (the default) disables logging of plans. For example, if you set it to 250ms then all statements that run 250ms or longer will be logged. Only superusers can change this setting.

`auto_explain.log_analyze (boolean)`

`auto_explain.log_analyze` causes `EXPLAIN ANALYZE` output, rather than just `EXPLAIN` output, to be printed when an execution plan is logged. This parameter is off by default. Only superusers can change this setting.

Note

When this parameter is on, per-plan-node timing occurs for all statements executed, whether or not they run long enough to actually get logged. This can have an extremely negative impact

on performance. Turning off `auto_explain.log_timing` ameliorates the performance cost, at the price of obtaining less information.

`auto_explain.log_buffers` (boolean)

`auto_explain.log_buffers` controls whether buffer usage statistics are printed when an execution plan is logged; it's equivalent to the `BUFFERS` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_wal` (boolean)

`auto_explain.log_wal` controls whether WAL usage statistics are printed when an execution plan is logged; it's equivalent to the `WAL` option of `EXPLAIN`. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_timing` (boolean)

`auto_explain.log_timing` controls whether per-node timing information is printed when an execution plan is logged; it's equivalent to the `TIMING` option of `EXPLAIN`. The overhead of repeatedly reading the system clock can slow down queries significantly on some systems, so it may be useful to set this parameter to off when only actual row counts, and not exact times, are needed. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is on by default. Only superusers can change this setting.

`auto_explain.log_triggers` (boolean)

`auto_explain.log_triggers` causes trigger execution statistics to be included when an execution plan is logged. This parameter has no effect unless `auto_explain.log_analyze` is enabled. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_verbose` (boolean)

`auto_explain.log_verbose` controls whether verbose details are printed when an execution plan is logged; it's equivalent to the `VERBOSE` option of `EXPLAIN`. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_settings` (boolean)

`auto_explain.log_settings` controls whether information about modified configuration options is printed when an execution plan is logged. Only options affecting query planning with value different from the built-in default value are included in the output. This parameter is off by default. Only superusers can change this setting.

`auto_explain.log_format` (enum)

`auto_explain.log_format` selects the `EXPLAIN` output format to be used. The allowed values are `text`, `xml`, `json`, and `yaml`. The default is `text`. Only superusers can change this setting.

`auto_explain.log_level` (enum)

`auto_explain.log_level` selects the log level at which `auto_explain` will log the query plan. Valid values are `DEBUG5`, `DEBUG4`, `DEBUG3`, `DEBUG2`, `DEBUG1`, `INFO`, `NOTICE`, `WARNING`, and `LOG`. The default is `LOG`. Only superusers can change this setting.

`auto_explain.log_nested_statements` (boolean)

`auto_explain.log_nested_statements` causes nested statements (statements executed inside a function) to be considered for logging. When it is off, only top-level query plans are logged. This parameter is off by default. Only superusers can change this setting.

```
auto_explain.sample_rate (real)
```

`auto_explain.sample_rate` causes `auto_explain` to only explain a fraction of the statements in each session. The default is 1, meaning explain all the queries. In case of nested statements, either all will be explained or none. Only superusers can change this setting.

In ordinary usage, these parameters are set in `postgresql.conf`, although superusers can alter them on-the-fly within their own sessions. Typical usage might be:

```
# postgresql.conf
session_preload_libraries = 'auto_explain'

auto_explain.log_min_duration = '3s'
```

F.5.2. Example

```
postgres=# LOAD 'auto_explain';
postgres=# SET auto_explain.log_min_duration = 0;
postgres=# SET auto_explain.log_analyze = true;
postgres=# SELECT count(*)
           FROM pg_class, pg_index
           WHERE oid = indrelid AND indisunique;
```

This might produce log output such as:

```
LOG:  duration: 0.196 ms planning: 0.548 ms plan:
       Query Text: SELECT count(*)
                   FROM pg_class, pg_index
                   WHERE oid = indrelid AND indisunique;
       Aggregate  (cost=16.79..16.80 rows=1 width=0) (actual time=3.626..3.627 rows=1
loops=1)
       -> Hash Join  (cost=4.17..16.55 rows=92 width=0) (actual time=3.349..3.594 rows=92
loops=1)
           Hash Cond: (pg_class.oid = pg_index.indrelid)
           -> Seq Scan on pg_class  (cost=0.00..9.55 rows=255 width=4) (actual
time=0.016..0.140 rows=255 loops=1)
           -> Hash   (cost=3.02..3.02 rows=92 width=4) (actual time=3.238..3.238 rows=92
loops=1)
                   Buckets: 1024  Batches: 1  Memory Usage: 4kB
           -> Seq Scan on pg_index  (cost=0.00..3.02 rows=92 width=4) (actual
time=0.008..3.187 rows=92 loops=1)
                   Filter: indisunique
```

Note that Postgres Pro added a new field to the output to show planning time.

Postgres Professional, Moscow, Russia

F.6. bloom

`bloom` provides an index access method based on *Bloom filters*.

A Bloom filter is a space-efficient data structure that is used to test whether an element is a member of a set. In the case of an index access method, it allows fast exclusion of non-matching tuples via signatures whose size is determined at index creation.

A signature is a lossy representation of the indexed attribute(s), and as such is prone to reporting false positives; that is, it may be reported that an element is in the set, when it is not. So index search results must always be rechecked using the actual attribute values from the heap entry. Larger signatures

reduce the odds of a false positive and thus reduce the number of useless heap visits, but of course also make the index larger and hence slower to scan.

This type of index is most useful when a table has many attributes and queries test arbitrary combinations of them. A traditional btree index is faster than a bloom index, but it can require many btree indexes to support all possible queries where one needs only a single bloom index. Note however that bloom indexes only support equality queries, whereas btree indexes can also perform inequality and range searches.

F.6.1. Parameters

A bloom index accepts the following parameters in its `WITH` clause:

`length`

Length of each signature (index entry) in bits. It is rounded up to the nearest multiple of 16. The default is 80 bits and the maximum is 4096.

`col1 – col32`

Number of bits generated for each index column. Each parameter's name refers to the number of the index column that it controls. The default is 2 bits and the maximum is 4095. Parameters for index columns not actually used are ignored.

F.6.2. Examples

This is an example of creating a bloom index:

```
CREATE INDEX bloomidx ON tbloom USING bloom (i1,i2,i3)
  WITH (length=80, col1=2, col2=2, col3=4);
```

The index is created with a signature length of 80 bits, with attributes `i1` and `i2` mapped to 2 bits, and attribute `i3` mapped to 4 bits. We could have omitted the `length`, `col1`, and `col2` specifications since those have the default values.

Here is a more complete example of bloom index definition and usage, as well as a comparison with equivalent btree indexes. The bloom index is considerably smaller than the btree index, and can perform better.

```
=# CREATE TABLE tbloom AS
  SELECT
    (random() * 1000000)::int as i1,
    (random() * 1000000)::int as i2,
    (random() * 1000000)::int as i3,
    (random() * 1000000)::int as i4,
    (random() * 1000000)::int as i5,
    (random() * 1000000)::int as i6
  FROM
    generate_series(1,10000000);
SELECT 10000000
```

A sequential scan over this large table takes a long time:

```
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
      QUERY PLAN
```

```
-----
Seq Scan on tbloom  (cost=0.00..2137.14 rows=3 width=24) (actual time=15.480..15.480
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.340 ms
```

```
Execution Time: 15.501 ms
(5 rows)
```

Even with the btree index defined the result will still be a sequential scan:

```
=# CREATE INDEX btreeidx ON tbloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('btreeidx'));
pg_size_pretty
-----
3976 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN

-----
Seq Scan on tbloom (cost=0.00..2137.00 rows=2 width=24) (actual time=12.604..12.604
rows=0 loops=1)
  Filter: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Filter: 100000
Planning Time: 0.155 ms
Execution Time: 12.617 ms
(5 rows)
```

Having the bloom index defined on the table is better than btree in handling this type of search:

```
=# CREATE INDEX bloomidx ON tbloom USING bloom (i1, i2, i3, i4, i5, i6);
CREATE INDEX
=# SELECT pg_size_pretty(pg_relation_size('bloomidx'));
pg_size_pretty
-----
1584 kB
(1 row)
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
QUERY PLAN

-----
Bitmap Heap Scan on tbloom (cost=1792.00..1799.69 rows=2 width=24) (actual
time=0.384..0.384 rows=0 loops=1)
  Recheck Cond: ((i2 = 898732) AND (i5 = 123451))
  Rows Removed by Index Recheck: 26
  Heap Blocks: exact=26
-> Bitmap Index Scan on bloomidx (cost=0.00..1792.00 rows=2 width=0) (actual
time=0.350..0.350 rows=26 loops=1)
  Index Cond: ((i2 = 898732) AND (i5 = 123451))
Planning Time: 0.122 ms
Execution Time: 0.407 ms
(8 rows)
```

Now, the main problem with the btree search is that btree is inefficient when the search conditions do not constrain the leading index column(s). A better strategy for btree is to create a separate index on each column. Then the planner will choose something like this:

```
=# CREATE INDEX btreeidx1 ON tbloom (i1);
CREATE INDEX
=# CREATE INDEX btreeidx2 ON tbloom (i2);
CREATE INDEX
=# CREATE INDEX btreeidx3 ON tbloom (i3);
```

```
CREATE INDEX
=# CREATE INDEX btreeidx4 ON tbloom (i4);
CREATE INDEX
=# CREATE INDEX btreeidx5 ON tbloom (i5);
CREATE INDEX
=# CREATE INDEX btreeidx6 ON tbloom (i6);
CREATE INDEX
=# EXPLAIN ANALYZE SELECT * FROM tbloom WHERE i2 = 898732 AND i5 = 123451;
                                QUERY PLAN

-----
Bitmap Heap Scan on tbloom  (cost=24.34..32.03 rows=2 width=24) (actual
time=0.032..0.033 rows=0 loops=1)
  Recheck Cond: ((i5 = 123451) AND (i2 = 898732))
    -> BitmapAnd  (cost=24.34..24.34 rows=2 width=0) (actual time=0.029..0.030 rows=0
loops=1)
      -> Bitmap Index Scan on btreeidx5  (cost=0.00..12.04 rows=500 width=0)
(actual time=0.029..0.029 rows=0 loops=1)
        Index Cond: (i5 = 123451)
      -> Bitmap Index Scan on btreeidx2  (cost=0.00..12.04 rows=500 width=0) (never
executed)
        Index Cond: (i2 = 898732)
Planning Time: 0.537 ms
Execution Time: 0.064 ms
(9 rows)
```

Although this query runs much faster than with either of the single indexes, we pay a penalty in index size. Each of the single-column btree indexes occupies 2 MB, so the total space needed is 12 MB, eight times the space used by the bloom index.

F.6.3. Operator Class Interface

An operator class for bloom indexes requires only a hash function for the indexed data type and an equality operator for searching. This example shows the operator class definition for the `text` data type:

```
CREATE OPERATOR CLASS text_ops
DEFAULT FOR TYPE text USING bloom AS
    OPERATOR      1      =(text, text),
    FUNCTION      1      hashtext(text);
```

F.6.4. Limitations

- Only operator classes for `int4` and `text` are included with the module.
- Only the `=` operator is supported for search. But it is possible to add support for arrays with union and intersection operations in the future.
- `bloom` access method doesn't support `UNIQUE` indexes.
- `bloom` access method doesn't support searching for `NULL` values.

F.6.5. Authors

Teodor Sigaev <teodor@postgrespro.ru>, Postgres Professional, Moscow, Russia

Alexander Korotkov <a.korotkov@postgrespro.ru>, Postgres Professional, Moscow, Russia

Oleg Bartunov <obartunov@postgrespro.ru>, Postgres Professional, Moscow, Russia

F.7. btree_gin

`btree_gin` provides sample GIN operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `"char"`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, `name`, `bool`, `bpchar`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they are useful for GIN testing and as a base for developing other GIN operator classes. Also, for queries that test both a GIN-indexable column and a B-tree-indexable column, it might be more efficient to create a multicolumn GIN index that uses one of these operator classes than to create two separate indexes that would have to be combined via bitmap ANDing.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.7.1. Example Usage

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIN (a);
-- query
SELECT * FROM test WHERE a < 10;
```

F.7.2. Authors

Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megeera/oddmuse/index.cgi/Gin> for additional information.

F.8. btree_gist

`btree_gist` provides GiST index operator classes that implement B-tree equivalent behavior for the data types `int2`, `int4`, `int8`, `float4`, `float8`, `numeric`, `timestamp with time zone`, `timestamp without time zone`, `time with time zone`, `time without time zone`, `date`, `interval`, `oid`, `money`, `char`, `varchar`, `text`, `bytea`, `bit`, `varbit`, `macaddr`, `macaddr8`, `inet`, `cidr`, `uuid`, and all enum types.

In general, these operator classes will not outperform the equivalent standard B-tree index methods, and they lack one major feature of the standard B-tree code: the ability to enforce uniqueness. However, they provide some other features that are not available with a B-tree index, as described below. Also, these operator classes are useful when a multicolumn GiST index is needed, wherein some of the columns are of data types that are only indexable with GiST but other columns are just simple data types. Lastly, these operator classes are useful for GiST testing and as a base for developing other GiST operator classes.

In addition to the typical B-tree search operators, `btree_gist` also provides index support for `<>` (“not equals”). This may be useful in combination with an [exclusion constraint](#), as described below.

Also, for data types for which there is a natural distance metric, `btree_gist` defines a distance operator `<->`, and provides GiST index support for nearest-neighbor searches using this operator. Distance operators are provided for `int2`, `int4`, `int8`, `float4`, `float8`, `timestamp with time zone`, `timestamp without time zone`, `time without time zone`, `date`, `interval`, `oid`, and `money`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.8.1. Example Usage

Simple example using `btree_gist` instead of `btree`:

```
CREATE TABLE test (a int4);
-- create index
CREATE INDEX testidx ON test USING GIST (a);
```

```
-- query
SELECT * FROM test WHERE a < 10;
-- nearest-neighbor search: find the ten entries closest to "42"
SELECT *, a <-> 42 AS dist FROM test ORDER BY a <-> 42 LIMIT 10;
```

Use an [exclusion constraint](#) to enforce the rule that a cage at a zoo can contain only one kind of animal:

```
=> CREATE TABLE zoo (
    cage    INTEGER,
    animal  TEXT,
    EXCLUDE USING GIST (cage WITH =, animal WITH <>)
);

=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'zebra');
INSERT 0 1
=> INSERT INTO zoo VALUES(123, 'lion');
ERROR:  conflicting key value violates exclusion constraint "zoo_cage_animal_excl"
DETAIL:  Key (cage, animal)=(123, lion) conflicts with existing key (cage,
        animal)=(123, zebra).
=> INSERT INTO zoo VALUES(124, 'lion');
INSERT 0 1
```

F.8.2. Upgrade notes for version 1.6

In version 1.6 `btree_gist` switched to using in-core distance operators, and its own implementations were removed. References to these operators in `btree_gist` opclasses will be updated automatically during the extension upgrade, but if the user has created objects referencing these operators or functions, then these objects must be dropped manually before updating the extension.

F.8.3. Authors

Teodor Sigaev (<teodor@stack.net>), Oleg Bartunov (<oleg@sai.msu.su>), Janko Richter (<janko-richter@yahoo.de>), and Paul Jungwirth (<pj@illuminatedcomputing.com>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information.

F.9. citext

The `citext` module provides a case-insensitive character string type, `citext`. Essentially, it internally calls `lower` when comparing values. Otherwise, it behaves almost exactly like `text`.

Tip

Consider using *nondeterministic collations* (see [Section 23.2.2.4](#)) instead of this module. They can be used for case-insensitive comparisons, accent-insensitive comparisons, and other combinations, and they handle more Unicode special cases correctly.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.9.1. Rationale

The standard approach to doing case-insensitive matches in Postgres Pro has been to use the `lower` function when comparing values, for example

```
SELECT * FROM tab WHERE lower(col) = LOWER(?);
```

This works reasonably well, but has a number of drawbacks:

- It makes your SQL statements verbose, and you always have to remember to use `lower` on both the column and the query value.
- It won't use an index, unless you create a functional index using `lower`.
- If you declare a column as `UNIQUE` or `PRIMARY KEY`, the implicitly generated index is case-sensitive. So it's useless for case-insensitive searches, and it won't enforce uniqueness case-insensitively.

The `citext` data type allows you to eliminate calls to `lower` in SQL queries, and allows a primary key to be case-insensitive. `citext` is locale-aware, just like `text`, which means that the matching of upper case and lower case characters is dependent on the rules of the database's `LC_CTYPE` setting. Again, this behavior is identical to the use of `lower` in queries. But because it's done transparently by the data type, you don't have to remember to do anything special in your queries.

F.9.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE users (  
    nick CITEXT PRIMARY KEY,  
    pass TEXT    NOT NULL  
);  
  
INSERT INTO users VALUES ( 'larry',  sha256(random())::text::bytea );  
INSERT INTO users VALUES ( 'Tom',    sha256(random())::text::bytea );  
INSERT INTO users VALUES ( 'Damian',  sha256(random())::text::bytea );  
INSERT INTO users VALUES ( 'NEAL',    sha256(random())::text::bytea );  
INSERT INTO users VALUES ( 'Bjørn',   sha256(random())::text::bytea );  
  
SELECT * FROM users WHERE nick = 'Larry';
```

The `SELECT` statement will return one tuple, even though the `nick` column was set to `larry` and the query was for `Larry`.

F.9.3. String Comparison Behavior

`citext` performs comparisons by converting each string to lower case (as though `lower` were called) and then comparing the results normally. Thus, for example, two strings are considered equal if `lower` would produce identical results for them.

In order to emulate a case-insensitive collation as closely as possible, there are `citext`-specific versions of a number of string-processing operators and functions. So, for example, the regular expression operators `~` and `~*` exhibit the same behavior when applied to `citext`: they both match case-insensitively. The same is true for `!~` and `!~*`, as well as for the `LIKE` operators `~~` and `~~*`, and `!~~` and `!~~*`. If you'd like to match case-sensitively, you can cast the operator's arguments to `text`.

Similarly, all of the following functions perform matching case-insensitively if their arguments are `citext`:

- `regexp_match()`
- `regexp_matches()`
- `regexp_replace()`
- `regexp_split_to_array()`
- `regexp_split_to_table()`
- `replace()`
- `split_part()`
- `strpos()`
- `translate()`

For the regexp functions, if you want to match case-sensitively, you can specify the “c” flag to force a case-sensitive match. Otherwise, you must cast to `text` before using one of these functions if you want case-sensitive behavior.

F.9.4. Limitations

- `citext`'s case-folding behavior depends on the `LC_CTYPE` setting of your database. How it compares values is therefore determined when the database is created. It is not truly case-insensitive in the terms defined by the Unicode standard. Effectively, what this means is that, as long as you're happy with your collation, you should be happy with `citext`'s comparisons. But if you have data in different languages stored in your database, users of one language may find their query results are not as expected if the collation is for another language.
- As of PostgreSQL 9.1, you can attach a `COLLATE` specification to `citext` columns or data values. Currently, `citext` operators will honor a non-default `COLLATE` specification while comparing case-folded strings, but the initial folding to lower case is always done according to the database's `LC_CTYPE` setting (that is, as though `COLLATE "default"` were given). This may be changed in a future release so that both steps follow the input `COLLATE` specification.
- `citext` is not as efficient as `text` because the operator functions and the B-tree comparison functions must make copies of the data and convert it to lower case for comparisons. Also, only `text` can support B-Tree deduplication. However, `citext` is slightly more efficient than using `lower` to get case-insensitive matching.
- `citext` doesn't help much if you need data to compare case-sensitively in some contexts and case-insensitively in other contexts. The standard answer is to use the `text` type and manually use the `lower` function when you need to compare case-insensitively; this works all right if case-insensitive comparison is needed only infrequently. If you need case-insensitive behavior most of the time and case-sensitive infrequently, consider storing the data as `citext` and explicitly casting the column to `text` when you want case-sensitive comparison. In either situation, you will need two indexes if you want both types of searches to be fast.
- The schema containing the `citext` operators must be in the current `search_path` (typically `public`); if it is not, the normal case-sensitive `text` operators will be invoked instead.
- The approach of lower-casing strings for comparison does not handle some Unicode special cases correctly, for example when one upper-case letter has two lower-case letter equivalents. Unicode distinguishes between *case mapping* and *case folding* for this reason. Use nondeterministic collations instead of `citext` to handle that correctly.

F.9.5. Author

David E. Wheeler <david@kineticcode.com>

Inspired by the original `citext` module by Donald Fraser.

F.10. cube

This module implements a data type `cube` for representing multidimensional cubes.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.10.1. Syntax

Table F.6 shows the valid external representations for the `cube` type. *x*, *y*, etc. denote floating-point numbers.

Table F.6. Cube External Representations

External Syntax	Meaning
<i>x</i>	A one-dimensional point (or, zero-length one-dimensional interval)

External Syntax	Meaning
<code>(x)</code>	Same as above
<code>x1, x2, ..., xn</code>	A point in n-dimensional space, represented internally as a zero-volume cube
<code>(x1, x2, ..., xn)</code>	Same as above
<code>(x), (y)</code>	A one-dimensional interval starting at <code>x</code> and ending at <code>y</code> or vice versa; the order does not matter
<code>[(x), (y)]</code>	Same as above
<code>(x1, ..., xn), (y1, ..., yn)</code>	An n-dimensional cube represented by a pair of its diagonally opposite corners
<code>[(x1, ..., xn), (y1, ..., yn)]</code>	Same as above

It does not matter which order the opposite corners of a cube are entered in. The `cube` functions automatically swap values if needed to create a uniform “lower left — upper right” internal representation. When the corners coincide, `cube` stores only one corner along with an “is point” flag to avoid wasting space.

White space is ignored on input, so `[ (x), (y) ]` is the same as `[ ( x ), ( y ) ]`.

F.10.2. Precision

Values are stored internally as 64-bit floating point numbers. This means that numbers with more than about 16 significant digits will be truncated.

F.10.3. Usage

[Table F.7](#) shows the specialized operators provided for type `cube`.

Table F.7. Cube Operators

Operator	Description
<code>cube && cube → boolean</code>	Do the cubes overlap?
<code>cube @> cube → boolean</code>	Does the first cube contain the second?
<code>cube <@ cube → boolean</code>	Is the first cube contained in the second?
<code>cube -> integer → float8</code>	Extracts the <i>n</i> -th coordinate of the cube (counting from 1).
<code>cube ~> integer → float8</code>	Extracts the <i>n</i> -th coordinate of the cube, counting in the following way: $n = 2 * k - 1$ means lower bound of <i>k</i> -th dimension, $n = 2 * k$ means upper bound of <i>k</i> -th dimension. Negative <i>n</i> denotes the inverse value of the corresponding positive coordinate. This operator is designed for KNN-GiST support.
<code>cube <-> cube → float8</code>	Computes the Euclidean distance between the two cubes.
<code>cube <#> cube → float8</code>	Computes the taxicab (L-1 metric) distance between the two cubes.
<code>cube <=> cube → float8</code>	Computes the Chebyshev (L-inf metric) distance between the two cubes.

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `cube`. These operators first compare the first coordinates, and if those are equal, compare the second coordinates, etc. They exist mainly to support the b-tree index operator class for `cube`, which can be useful for example if you would like a `UNIQUE` constraint on a `cube` column. Otherwise, this ordering is not of much practical use.

The `cube` module also provides a GiST index operator class for `cube` values. A `cube` GiST index can be used to search for values using the `=`, `&&`, `@>`, and `<@` operators in `WHERE` clauses.

In addition, a `cube` GiST index can be used to find nearest neighbors using the metric operators `<->`, `<#>`, and `<=>` in `ORDER BY` clauses. For example, the nearest neighbor of the 3-D point (0.5, 0.5, 0.5) could be found efficiently with:

```
SELECT c FROM test ORDER BY c <-> cube(array[0.5,0.5,0.5]) LIMIT 1;
```

The `~>` operator can also be used in this way to efficiently retrieve the first few values sorted by a selected coordinate. For example, to get the first few cubes ordered by the first coordinate (lower left corner) ascending one could use the following query:

```
SELECT c FROM test ORDER BY c ~> 1 LIMIT 5;
```

And to get 2-D cubes ordered by the first coordinate of the upper right corner descending:

```
SELECT c FROM test ORDER BY c ~> 3 DESC LIMIT 5;
```

[Table F.8](#) shows the available functions.

Table F.8. Cube Functions

Function	Description	Example(s)
<code>cube (float8) → cube</code>	Makes a one dimensional cube with both coordinates the same.	<code>cube(1) → (1)</code>
<code>cube (float8, float8) → cube</code>	Makes a one dimensional cube.	<code>cube(1,2) → (1), (2)</code>
<code>cube (float8[]) → cube</code>	Makes a zero-volume cube using the coordinates defined by the array.	<code>cube(ARRAY[1,2,3]) → (1, 2, 3)</code>
<code>cube (float8[], float8[]) → cube</code>	Makes a cube with upper right and lower left coordinates as defined by the two arrays, which must be of the same length.	<code>cube(ARRAY[1,2], ARRAY[3,4]) → (1, 2), (3, 4)</code>
<code>cube (cube, float8) → cube</code>	Makes a new cube by adding a dimension on to an existing cube, with the same values for both endpoints of the new coordinate. This is useful for building cubes piece by piece from calculated values.	<code>cube(' (1,2), (3,4) '::cube, 5) → (1, 2, 5), (3, 4, 5)</code>
<code>cube (cube, float8, float8) → cube</code>	Makes a new cube by adding a dimension on to an existing cube. This is useful for building cubes piece by piece from calculated values.	

Function	Description	Example(s)
		<code>cube(' (1,2), (3,4) '::cube, 5, 6)</code> $\rightarrow (1, 2, 5), (3, 4, 6)$
<code>cube_dim (cube)</code>	<code>→ integer</code> Returns the number of dimensions of the cube.	<code>cube_dim(' (1,2), (3,4) ')</code> $\rightarrow 2$
<code>cube_ll_coord (cube, integer)</code>	<code>→ float8</code> Returns the n -th coordinate value for the lower left corner of the cube.	<code>cube_ll_coord(' (1,2), (3,4) ', 2)</code> $\rightarrow 2$
<code>cube_ur_coord (cube, integer)</code>	<code>→ float8</code> Returns the n -th coordinate value for the upper right corner of the cube.	<code>cube_ur_coord(' (1,2), (3,4) ', 2)</code> $\rightarrow 4$
<code>cube_is_point (cube)</code>	<code>→ boolean</code> Returns true if the cube is a point, that is, the two defining corners are the same.	<code>cube_is_point(cube(1,1))</code> $\rightarrow t$
<code>cube_distance (cube, cube)</code>	<code>→ float8</code> Returns the distance between two cubes. If both cubes are points, this is the normal distance function.	<code>cube_distance(' (1,2) ', ' (3,4) ')</code> $\rightarrow 2.8284271247461903$
<code>cube_subset (cube, integer[])</code>	<code>→ cube</code> Makes a new cube from an existing cube, using a list of dimension indexes from an array. Can be used to extract the endpoints of a single dimension, or to drop dimensions, or to reorder them as desired.	<code>cube_subset(cube(' (1,3,5), (6,7,8) '), ARRAY[2])</code> $\rightarrow (3), (7)$ <code>cube_subset(cube(' (1,3,5), (6,7,8) '), ARRAY[3,2,1,1])</code> $\rightarrow (5, 3, 1, 1), (8, 7, 6, 6)$
<code>cube_union (cube, cube)</code>	<code>→ cube</code> Produces the union of two cubes.	<code>cube_union(' (1,2) ', ' (3,4) ')</code> $\rightarrow (1, 2), (3, 4)$
<code>cube_inter (cube, cube)</code>	<code>→ cube</code> Produces the intersection of two cubes.	<code>cube_inter(' (1,2) ', ' (3,4) ')</code> $\rightarrow (3, 4), (1, 2)$
<code>cube_enlarge (c cube, r double, n integer)</code>	<code>→ cube</code> Increases the size of the cube by the specified radius r in at least n dimensions. If the radius is negative the cube is shrunk instead. All defined dimensions are changed by the radius r . Lower-left coordinates are decreased by r and upper-right coordinates are increased by r . If a lower-left coordinate is increased to more than the corresponding upper-right coordinate (this can only happen when $r < 0$) then both coordinates are set to their average. If n is greater than the number of defined dimensions and the cube is being enlarged ($r > 0$), then extra dimensions are added to make n altogether; 0 is used as the initial value for the extra coordinates. This function is useful for creating bounding boxes around a point for searching for nearby points.	<code>cube_enlarge(' (1,2), (3,4) ', 0.5, 3)</code> $\rightarrow (0.5, 1.5, -0.5), (3.5, 4.5, 0.5)$

F.10.4. Defaults

I believe this union:

```
select cube_union('(0,5,2),(2,3,1)', '0');
cube_union
-----
(0, 0, 0),(2, 5, 2)
(1 row)
```

does not contradict common sense, neither does the intersection

```
select cube_inter('(0,-1),(1,1)', '(-2),(2)');
cube_inter
-----
(0, 0),(1, 0)
(1 row)
```

In all binary operations on differently-dimensioned cubes, I assume the lower-dimensional one to be a Cartesian projection, i. e., having zeroes in place of coordinates omitted in the string representation. The above examples are equivalent to:

```
cube_union('(0,5,2),(2,3,1)', '(0,0,0),(0,0,0)');
cube_inter('(0,-1),(1,1)', '(-2,0),(2,0)');
```

The following containment predicate uses the point syntax, while in fact the second argument is internally represented by a box. This syntax makes it unnecessary to define a separate point type and functions for (box,point) predicates.

```
select cube_contains('(0,0),(1,1)', '0.5,0.5');
cube_contains
-----
t
(1 row)
```

F.10.5. Notes

For examples of usage, see the regression test `sql/cube.sql`.

To make it harder for people to break things, there is a limit of 100 on the number of dimensions of cubes. This is set in `cubedata.h` if you need something bigger.

F.10.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>), and to his former student Andy Dong for his example written for Illustra. I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

Minor updates to this package were made by Bruno Wolff III <bruno@wolff.to> in August/September of 2002. These include changing the precision from single precision to double precision and adding some new functions.

Additional updates were made by Joshua Reich <josh@root.net> in July 2006. These include `cube(float8[], float8[])` and cleaning up the code to use the V1 call protocol instead of the deprecated V0 protocol.

F.11. dblink

`dblink` is a module that supports connections to other Postgres Pro databases from within a database session.

See also [postgres_fdw](#), which provides roughly the same functionality using a more modern and standards-compliant infrastructure.

dblink_connect

`dblink_connect` — opens a persistent connection to a remote database

Synopsis

```
dblink_connect(text connstr) returns text
dblink_connect(text connname, text connstr) returns text
```

Description

`dblink_connect()` establishes a connection to a remote Postgres Pro database. The server and database to be contacted are identified through a standard libpq connection string. Optionally, a name can be assigned to the connection. Multiple named connections can be open at once, but only one unnamed connection is permitted at a time. The connection will persist until closed or until the database session is ended.

The connection string may also be the name of an existing foreign server. It is recommended to use the foreign-data wrapper `dblink_fdw` when defining the foreign server. See the example below, as well as [CREATE SERVER](#) and [CREATE USER MAPPING](#).

Arguments

connname

The name to use for this connection; if omitted, an unnamed connection is opened, replacing any existing unnamed connection.

connstr

libpq-style connection info string, for example `hostaddr=127.0.0.1 port=5432 dbname=mydb user=postgres password=mypasswd options=-csearch_path=`. For details see [Section 35.1.1](#). Alternatively, the name of a foreign server.

Return Value

Returns status, which is always OK (since any error causes the function to throw an error instead of returning).

Notes

If untrusted users have access to a database that has not adopted a [secure schema usage pattern](#), begin each session by removing publicly-writable schemas from `search_path`. One could, for example, add `options=-csearch_path=` to *connstr*. This consideration is not specific to `dblink`; it applies to every interface for executing arbitrary SQL commands.

Only superusers may use `dblink_connect` to create non-password-authenticated connections. If non-superusers need this capability, use `dblink_connect_u` instead.

It is unwise to choose connection names that contain equal signs, as this opens a risk of confusion with connection info strings in other `dblink` functions.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
      OK
(1 row)

SELECT dblink_connect('myconn', 'dbname=postgres options=-csearch_path=');
```

```

dblink_connect
-----
OK
(1 row)

-- FOREIGN DATA WRAPPER functionality
-- Note: local connection must require password authentication for this to work
properly
--      Otherwise, you will receive the following error from dblink_connect():
--      ERROR: password is required
--      DETAIL: Non-superuser cannot connect if the server does not request a
password.
--      HINT: Target server's authentication method must be changed.

CREATE SERVER fdtest FOREIGN DATA WRAPPER dblink_fdw OPTIONS (hostaddr '127.0.0.1',
    dbname 'contrib_regression');

CREATE USER regress_dblink_user WITH PASSWORD 'secret';
CREATE USER MAPPING FOR regress_dblink_user SERVER fdtest OPTIONS (user
    'regress_dblink_user', password 'secret');
GRANT USAGE ON FOREIGN SERVER fdtest TO regress_dblink_user;
GRANT SELECT ON TABLE foo TO regress_dblink_user;

\set ORIGINAL_USER :USER
\c - regress_dblink_user
SELECT dblink_connect('myconn', 'fdtest');
dblink_connect
-----
OK
(1 row)

SELECT * FROM dblink('myconn', 'SELECT * FROM foo') AS t(a int, b text, c text[]);
 a | b | c
-----+-----+-----
 0 | a | {a0,b0,c0}
 1 | b | {a1,b1,c1}
 2 | c | {a2,b2,c2}
 3 | d | {a3,b3,c3}
 4 | e | {a4,b4,c4}
 5 | f | {a5,b5,c5}
 6 | g | {a6,b6,c6}
 7 | h | {a7,b7,c7}
 8 | i | {a8,b8,c8}
 9 | j | {a9,b9,c9}
10 | k | {a10,b10,c10}
(11 rows)

\c - :ORIGINAL_USER
REVOKE USAGE ON FOREIGN SERVER fdtest FROM regress_dblink_user;
REVOKE SELECT ON TABLE foo FROM regress_dblink_user;
DROP USER MAPPING FOR regress_dblink_user SERVER fdtest;
DROP USER regress_dblink_user;
DROP SERVER fdtest;

```

dblink_connect_u

`dblink_connect_u` — opens a persistent connection to a remote database, insecurely

Synopsis

```
dblink_connect_u(text connstr) returns text  
dblink_connect_u(text connname, text connstr) returns text
```

Description

`dblink_connect_u()` is identical to `dblink_connect()`, except that it will allow non-superusers to connect using any authentication method.

If the remote server selects an authentication method that does not involve a password, then impersonation and subsequent escalation of privileges can occur, because the session will appear to have originated from the user as which the local Postgres Pro server runs. Also, even if the remote server does demand a password, it is possible for the password to be supplied from the server environment, such as a `~/.pgpass` file belonging to the server's user. This opens not only a risk of impersonation, but the possibility of exposing a password to an untrustworthy remote server. Therefore, `dblink_connect_u()` is initially installed with all privileges revoked from `PUBLIC`, making it un-callable except by superusers. In some situations it may be appropriate to grant `EXECUTE` permission for `dblink_connect_u()` to specific users who are considered trustworthy, but this should be done with care. It is also recommended that any `~/.pgpass` file belonging to the server's user *not* contain any records specifying a wildcard host name.

For further details see `dblink_connect()`.

dblink_disconnect

`dblink_disconnect` — closes a persistent connection to a remote database

Synopsis

```
dblink_disconnect() returns text
dblink_disconnect(text connname) returns text
```

Description

`dblink_disconnect()` closes a connection previously opened by `dblink_connect()`. The form with no arguments closes an unnamed connection.

Arguments

connname

The name of a named connection to be closed.

Return Value

Returns status, which is always `OK` (since any error causes the function to throw an error instead of returning).

Examples

```
SELECT dblink_disconnect();
 dblink_disconnect
-----
      OK
(1 row)

SELECT dblink_disconnect('myconn');
 dblink_disconnect
-----
      OK
(1 row)
```

dblink

`dblink` — executes a query in a remote database

Synopsis

```
dblink(text connname, text sql [, bool fail_on_error]) returns setof record
dblink(text connstr, text sql [, bool fail_on_error]) returns setof record
dblink(text sql [, bool fail_on_error]) returns setof record
```

Description

`dblink` executes a query (usually a `SELECT`, but it can be any SQL statement that returns rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL query that you wish to execute in the remote database, for example `select * from foo`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a `NOTICE`, and the function returns no rows.

Return Value

The function returns the row(s) produced by the query. Since `dblink` can be used with any query, it is declared to return `record`, rather than specifying any particular set of columns. This means that you must specify the expected set of columns in the calling query — otherwise Postgres Pro would not know what to expect. Here is an example:

```
SELECT *
FROM dblink('dbname=mydb options=-csearch_path=',
            'select pronomame, prosrc from pg_proc')
AS t1(pronomame name, prosrc text)
WHERE pronomame LIKE 'bytea%';
```

The “alias” part of the `FROM` clause must specify the column names and types that the function will return. (Specifying column names in an alias is actually standard SQL syntax, but specifying column types is a Postgres Pro extension.) This allows the system to understand what `*` should expand to, and what `pronomame` in the `WHERE` clause refers to, in advance of trying to execute the function. At run time, an error will be thrown if the actual query result from the remote database does not have the same number of columns shown in the `FROM` clause. The column names need not match, however, and `dblink` does not insist on exact type matches either. It will succeed so long as the returned data strings are valid input for the column type declared in the `FROM` clause.

Notes

A convenient way to use `dblink` with predetermined queries is to create a view. This allows the column type information to be buried in the view, instead of having to spell it out in every query. For example,

```
CREATE VIEW myremote_pg_proc AS
  SELECT *
    FROM dblink('dbname=postgres options=-csearch_path=',
                'select proname, prosrc from pg_proc')
    AS t1(proname name, prosrc text);

SELECT * FROM myremote_pg_proc WHERE proname LIKE 'bytea%';
```

Examples

```
SELECT * FROM dblink('dbname=postgres options=-csearch_path=',
                    'select proname, prosrc from pg_proc')
  AS t1(proname name, prosrc text) WHERE proname LIKE 'bytea%';
 proname | prosrc
-----+-----
 byteacat | byteacat
 byteaeq  | byteaeq
 bytealt  | bytealt

(14 rows)

dblink_exec

`dblink_exec` — executes a command in a remote database

Synopsis

```
dblink_exec(text connname, text sql [, bool fail_on_error]) returns text
dblink_exec(text connstr, text sql [, bool fail_on_error]) returns text
dblink_exec(text sql [, bool fail_on_error]) returns text
```

Description

`dblink_exec` executes a command (that is, any SQL statement that doesn't return rows) in a remote database.

When two `text` arguments are given, the first one is first looked up as a persistent connection's name; if found, the command is executed on that connection. If not found, the first argument is treated as a connection info string as for `dblink_connect`, and the indicated connection is made just for the duration of this command.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

connstr

A connection info string, as previously described for `dblink_connect`.

sql

The SQL command that you wish to execute in the remote database, for example `insert into foo values (0, 'a', '{"a0","b0","c0"}')`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either the command's status string or `ERROR`.

Examples

```
SELECT dblink_connect('dbname=dblink_test_standby');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_exec('insert into foo values(21, ''z'', ''{"a0","b0","c0"}'');');
 dblink_exec
-----
 INSERT 943366 1
(1 row)

SELECT dblink_connect('myconn', 'dbname=regression');
 dblink_connect
```

```
-----
OK
(1 row)

SELECT dblink_exec('myconn', 'insert into foo values(21, ''z'',
''{"a0","b0","c0"}'');');
      dblink_exec
-----
INSERT 6432584 1
(1 row)

SELECT dblink_exec('myconn', 'insert into pg_class values (''foo''),false);
NOTICE:  sql error
DETAIL:  ERROR:  null value in column "relnamespace" violates not-null constraint

      dblink_exec
-----
ERROR
(1 row)
```

dblink_open

`dblink_open` — opens a cursor in a remote database

Synopsis

```
dblink_open(text cursorname, text sql [, bool fail_on_error]) returns text
dblink_open(text connname, text cursorname, text sql [, bool fail_on_error]) returns
text
```

Description

`dblink_open()` opens a cursor in a remote database. The cursor can subsequently be manipulated with `dblink_fetch()` and `dblink_close()`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name to assign to this cursor.

sql

The `SELECT` statement that you wish to execute in the remote database, for example `select * from pg_class`.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

Since a cursor can only persist within a transaction, `dblink_open` starts an explicit transaction block (`BEGIN`) on the remote side, if the remote side was not already within a transaction. This transaction will be closed again when the matching `dblink_close` is executed. Note that if you use `dblink_exec` to change data between `dblink_open` and `dblink_close`, and then an error occurs or you use `dblink_disconnect` before `dblink_close`, your change *will be lost* because the transaction will be aborted.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
-----
OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
dblink_open
-----
OK
(1 row)
```

dblink_fetch

`dblink_fetch` — returns rows from an open cursor in a remote database

Synopsis

```
dblink_fetch(text cursorname, int howmany [, bool fail_on_error]) returns setof record
dblink_fetch(text connname, text cursorname, int howmany [, bool fail_on_error])
  returns setof record
```

Description

`dblink_fetch` fetches rows from a cursor previously established by `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to fetch from.

howmany

The maximum number of rows to retrieve. The next *howmany* rows are fetched, starting at the current cursor position, moving forward. Once the cursor has reached its end, no more rows are produced.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

The function returns the row(s) fetched from the cursor. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

Notes

On a mismatch between the number of return columns specified in the `FROM` clause, and the actual number of columns returned by the remote cursor, an error will be thrown. In this event, the remote cursor is still advanced by as many rows as it would have been if the error had not occurred. The same is true for any other error occurring in the local query after the remote `FETCH` has been done.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
dblink_connect
```

```
-----
OK
(1 row)
```

```
SELECT dblink_open('foo', 'select proname, prosrc from pg_proc where proname like
''bytea%'');
dblink_open
```

```
-----
OK
(1 row)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteacat | byteacat
 byteacmp | byteacmp
 byteaeq  | byteaeq
 byteage  | byteage
 byteagt  | byteagt
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteain  | byteain
 byteale  | byteale
 bytealike| bytealike
 bytealt  | bytealt
 byteane  | byteane
(5 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
 byteanlike| byteanlike
 byteaout  | byteaout
(2 rows)
```

```
SELECT * FROM dblink_fetch('foo', 5) AS (funcname name, source text);
 funcname | source
-----+-----
(0 rows)
```

dblink_close

`dblink_close` — closes a cursor in a remote database

Synopsis

```
dblink_close(text cursorname [, bool fail_on_error]) returns text
dblink_close(text connname, text cursorname [, bool fail_on_error]) returns text
```

Description

`dblink_close` closes a cursor previously opened with `dblink_open`.

Arguments

connname

Name of the connection to use; omit this parameter to use the unnamed connection.

cursorname

The name of the cursor to close.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function's return value is set to `ERROR`.

Return Value

Returns status, either `OK` or `ERROR`.

Notes

If `dblink_open` started an explicit transaction block, and this is the last remaining open cursor in this connection, `dblink_close` will issue the matching `COMMIT`.

Examples

```
SELECT dblink_connect('dbname=postgres options=-csearch_path=');
 dblink_connect
-----
 OK
(1 row)

SELECT dblink_open('foo', 'select proname, prosrc from pg_proc');
 dblink_open
-----
 OK
(1 row)

SELECT dblink_close('foo');
 dblink_close
-----
 OK
(1 row)
```

dblink_get_connections

`dblink_get_connections` — returns the names of all open named dblink connections

Synopsis

```
dblink_get_connections() returns text[]
```

Description

`dblink_get_connections` returns an array of the names of all open named dblink connections.

Return Value

Returns a text array of connection names, or NULL if none.

Examples

```
SELECT dblink_get_connections();
```

dblink_error_message

`dblink_error_message` — gets last error message on the named connection

Synopsis

`dblink_error_message(text connname)` returns text

Description

`dblink_error_message` fetches the most recent remote error message for a given connection.

Arguments

connname

Name of the connection to use.

Return Value

Returns last error message, or OK if there has been no error in this connection.

Notes

When asynchronous queries are initiated by `dblink_send_query`, the error message associated with the connection might not get updated until the server's response message is consumed. This typically means that `dblink_is_busy` or `dblink_get_result` should be called prior to `dblink_error_message`, so that any error generated by the asynchronous query will be visible.

Examples

```
SELECT dblink_error_message('dtest1');
```

dblink_send_query

`dblink_send_query` — sends an async query to a remote database

Synopsis

`dblink_send_query(text connname, text sql)` returns `int`

Description

`dblink_send_query` sends a query to be executed asynchronously, that is, without immediately waiting for the result. There must not be an async query already in progress on the connection.

After successfully dispatching an async query, completion status can be checked with `dblink_is_busy`, and the results are ultimately collected with `dblink_get_result`. It is also possible to attempt to cancel an active async query using `dblink_cancel_query`.

Arguments

connname

Name of the connection to use.

sql

The SQL statement that you wish to execute in the remote database, for example `select * from pg_class`.

Return Value

Returns 1 if the query was successfully dispatched, 0 otherwise.

Examples

```
SELECT dblink_send_query('dtest1', 'SELECT * FROM foo WHERE f1 < 3');
```

dblink_is_busy

`dblink_is_busy` — checks if connection is busy with an async query

Synopsis

```
dblink_is_busy(text connname) returns int
```

Description

`dblink_is_busy` tests whether an async query is in progress.

Arguments

connname

Name of the connection to check.

Return Value

Returns 1 if connection is busy, 0 if it is not busy. If this function returns 0, it is guaranteed that `dblink_get_result` will not block.

Examples

```
SELECT dblink_is_busy('dtest1');
```

dblink_get_notify

dblink_get_notify — retrieve async notifications on a connection

Synopsis

```
dblink_get_notify() returns setof (notify_name text, be_pid int, extra text)
dblink_get_notify(text connname) returns setof (notify_name text, be_pid int, extra
text)
```

Description

dblink_get_notify retrieves notifications on either the unnamed connection, or on a named connection if specified. To receive notifications via dblink, LISTEN must first be issued, using dblink_exec. For details see [LISTEN](#) and [NOTIFY](#).

Arguments

connname

The name of a named connection to get notifications on.

Return Value

Returns setof (notify_name text, be_pid int, extra text), or an empty set if none.

Examples

```
SELECT dblink_exec('LISTEN virtual');
dblink_exec
-----
LISTEN
(1 row)
```

```
SELECT * FROM dblink_get_notify();
notify_name | be_pid | extra
-----+-----+-----
(0 rows)
```

```
NOTIFY virtual;
NOTIFY
```

```
SELECT * FROM dblink_get_notify();
notify_name | be_pid | extra
-----+-----+-----
virtual     | 1229   |
(1 row)
```

dblink_get_result

`dblink_get_result` — gets an async query result

Synopsis

```
dblink_get_result(text connname [, bool fail_on_error]) returns setof record
```

Description

`dblink_get_result` collects the results of an asynchronous query previously sent with `dblink_send_query`. If the query is not already completed, `dblink_get_result` will wait until it is.

Arguments

connname

Name of the connection to use.

fail_on_error

If true (the default when omitted) then an error thrown on the remote side of the connection causes an error to also be thrown locally. If false, the remote error is locally reported as a NOTICE, and the function returns no rows.

Return Value

For an async query (that is, a SQL statement returning rows), the function returns the row(s) produced by the query. To use this function, you will need to specify the expected set of columns, as previously discussed for `dblink`.

For an async command (that is, a SQL statement not returning rows), the function returns a single row with a single text column containing the command's status string. It is still necessary to specify that the result will have a single text column in the calling `FROM` clause.

Notes

This function *must* be called if `dblink_send_query` returned 1. It must be called once for each query sent, and one additional time to obtain an empty set result, before the connection can be used again.

When using `dblink_send_query` and `dblink_get_result`, `dblink` fetches the entire remote query result before returning any of it to the local query processor. If the query returns a large number of rows, this can result in transient memory bloat in the local session. It may be better to open such a query as a cursor with `dblink_open` and then fetch a manageable number of rows at a time. Alternatively, use plain `dblink()`, which avoids memory bloat by spooling large result sets to disk.

Examples

```
contrib_regression=# SELECT dblink_connect('dtest1', 'dbname=contrib_regression');
dblink_connect
-----
OK
(1 row)

contrib_regression=# SELECT * FROM
contrib_regression-# dblink_send_query('dtest1', 'select * from foo where f1 < 3') AS
t1;
t1
----
1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 |      f3
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 | f3
----+-----+-----
(0 rows)
```

```
contrib_regression=# SELECT * FROM
contrib_regression=# dblink_send_query('dtest1', 'select * from foo where f1 < 3;
select * from foo where f1 > 6') AS t1;
```

```
t1
----
 1
(1 row)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 |      f3
----+-----+-----
 0 | a  | {a0,b0,c0}
 1 | b  | {a1,b1,c1}
 2 | c  | {a2,b2,c2}
(3 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 |      f3
----+-----+-----
 7 | h  | {a7,b7,c7}
 8 | i  | {a8,b8,c8}
 9 | j  | {a9,b9,c9}
10 | k  | {a10,b10,c10}
(4 rows)
```

```
contrib_regression=# SELECT * FROM dblink_get_result('dtest1') AS t1(f1 int, f2 text,
f3 text[]);
```

```
f1 | f2 | f3
----+-----+-----
(0 rows)
```

dblink_cancel_query

`dblink_cancel_query` — cancels any active query on the named connection

Synopsis

```
dblink_cancel_query(text connname) returns text
```

Description

`dblink_cancel_query` attempts to cancel any query that is in progress on the named connection. Note that this is not certain to succeed (since, for example, the remote query might already have finished). A cancel request simply improves the odds that the query will fail soon. You must still complete the normal query protocol, for example by calling `dblink_get_result`.

Arguments

connname

Name of the connection to use.

Return Value

Returns `OK` if the cancel request has been sent, or the text of an error message on failure.

Examples

```
SELECT dblink_cancel_query('dtest1');
```

dblink_get_pkey

`dblink_get_pkey` — returns the positions and field names of a relation's primary key fields

Synopsis

```
dblink_get_pkey(text relname) returns setof dblink_pkey_results
```

Description

`dblink_get_pkey` provides information about the primary key of a relation in the local database. This is sometimes useful in generating queries to be sent to remote databases.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

Return Value

Returns one row for each primary key field, or no rows if the relation has no primary key. The result row type is defined as

```
CREATE TYPE dblink_pkey_results AS (position int, colname text);
```

The `position` column simply runs from 1 to *N*; it is the number of the field within the primary key, not the number within the table's columns.

Examples

```
CREATE TABLE foobar (  
    f1 int,  
    f2 int,  
    f3 int,  
    PRIMARY KEY (f1, f2, f3)  
);  
CREATE TABLE  
  
SELECT * FROM dblink_get_pkey('foobar');  
 position | colname  
-----+-----  
        1 | f1  
        2 | f2  
        3 | f3  
(3 rows)
```

dblink_build_sql_insert

`dblink_build_sql_insert` — builds an `INSERT` statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_insert(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_insert` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL `INSERT` command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.)

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting `INSERT` command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_insert('foo', '1 2', 2, '{"1", "a"}', '{"1", "b''a"}');  
       dblink_build_sql_insert
```

```
INSERT INTO foo(f1,f2,f3) VALUES('1','b' 'a','1')
(1 row)
```

dblink_build_sql_delete

`dblink_build_sql_delete` — builds a DELETE statement using supplied values for primary key field values

Synopsis

```
dblink_build_sql_delete(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_delete` can be useful in doing selective replication of a local table to a remote database. It builds a SQL DELETE command that will delete the row with the given primary key values.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

tgt_pk_att_vals_array

Values of the primary key fields to be used in the resulting DELETE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_delete('MyFoo', '1 2', 2, '{"1", "b"}');  
      dblink_build_sql_delete  
-----  
DELETE FROM "MyFoo" WHERE f1='1' AND f2='b'  
(1 row)
```

dblink_build_sql_update

`dblink_build_sql_update` — builds an UPDATE statement using a local tuple, replacing the primary key field values with alternative supplied values

Synopsis

```
dblink_build_sql_update(text relname,  
                        int2vector primary_key_attnums,  
                        integer num_primary_key_atts,  
                        text[] src_pk_att_vals_array,  
                        text[] tgt_pk_att_vals_array) returns text
```

Description

`dblink_build_sql_update` can be useful in doing selective replication of a local table to a remote database. It selects a row from the local table based on primary key, and then builds a SQL UPDATE command that will duplicate that row, but with the primary key values replaced by the values in the last argument. (To make an exact copy of the row, just specify the same values for the last two arguments.) The UPDATE command always assigns all fields of the row — the main difference between this and `dblink_build_sql_insert` is that it's assumed that the target row already exists in the remote table.

Arguments

relname

Name of a local relation, for example `foo` or `myschema.mytab`. Include double quotes if the name is mixed-case or contains special characters, for example `"FooBar"`; without quotes, the string will be folded to lower case.

primary_key_attnums

Attribute numbers (1-based) of the primary key fields, for example `1 2`.

num_primary_key_atts

The number of primary key fields.

src_pk_att_vals_array

Values of the primary key fields to be used to look up the local tuple. Each field is represented in text form. An error is thrown if there is no local row with these primary key values.

tgt_pk_att_vals_array

Values of the primary key fields to be placed in the resulting UPDATE command. Each field is represented in text form.

Return Value

Returns the requested SQL statement as text.

Notes

As of PostgreSQL 9.0, the attribute numbers in *primary_key_attnums* are interpreted as logical column numbers, corresponding to the column's position in `SELECT * FROM relname`. Previous versions interpreted the numbers as physical column positions. There is a difference if any column(s) to the left of the indicated column have been dropped during the lifetime of the table.

Examples

```
SELECT dblink_build_sql_update('foo', '1 2', 2, '{"1", "a"}', '{"1", "b"}');  
       dblink_build_sql_update
```

```
UPDATE foo SET f1='1',f2='b',f3='1' WHERE f1='1' AND f2='b'
(1 row)
```

F.12. dict_int

`dict_int` is an example of an add-on dictionary template for full-text search. The motivation for this example dictionary is to control the indexing of integers (signed and unsigned), allowing such numbers to be indexed while preventing excessive growth in the number of unique words, which greatly affects the performance of searching.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.12.1. Configuration

The dictionary accepts three options:

- The `maxlen` parameter specifies the maximum number of digits allowed in an integer word. The default value is 6.
- The `rejectlong` parameter specifies whether an overlength integer should be truncated or ignored. If `rejectlong` is `false` (the default), the dictionary returns the first `maxlen` digits of the integer. If `rejectlong` is `true`, the dictionary treats an overlength integer as a stop word, so that it will not be indexed. Note that this also means that such an integer cannot be searched for.
- The `absval` parameter specifies whether leading “+” or “-” signs should be removed from integer words. The default is `false`. When `true`, the sign is removed before `maxlen` is applied.

F.12.2. Usage

Installing the `dict_int` extension creates a text search template `intdict_template` and a dictionary `intdict` based on it, with the default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY intdict (MAXLEN = 4, REJECTLONG = true);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb# select ts_lexize('intdict', '12345678');
 ts_lexize
-----
 {123456}
```

but real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
    ALTER MAPPING FOR int, uint WITH intdict;
```

F.13. dict_xsyn

`dict_xsyn` (Extended Synonym Dictionary) is an example of an add-on dictionary template for full-text search. This dictionary type replaces words with groups of their synonyms, and so makes it possible to search for a word using any of its synonyms.

F.13.1. Configuration

A `dict_xsyn` dictionary accepts the following options:

- `matchorig` controls whether the original word is accepted by the dictionary. Default is `true`.
- `matchsynonyms` controls whether the synonyms are accepted by the dictionary. Default is `false`.
- `keeporig` controls whether the original word is included in the dictionary's output. Default is `true`.

- `keepsynonyms` controls whether the synonyms are included in the dictionary's output. Default is `true`.
- `rules` is the base name of the file containing the list of synonyms. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `rules` parameter).

The rules file has the following format:

- Each line represents a group of synonyms for a single word, which is given first on the line. Synonyms are separated by whitespace, thus:
`word syn1 syn2 syn3`
- The sharp (`#`) sign is a comment delimiter. It may appear at any position in a line. The rest of the line will be skipped.

Look at `xsyn_sample.rules`, which is installed in `$$SHAREDIR/tsearch_data/`, for an example.

F.13.2. Usage

Installing the `dict_xsyn` extension creates a text search template `xsyn_template` and a dictionary `xsyn` based on it, with default parameters. You can alter the parameters, for example

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false);
ALTER TEXT SEARCH DICTIONARY
```

or create new dictionaries based on the template.

To test the dictionary, you can try

```
mydb=# SELECT ts_lexize('xsyn', 'word');
         ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'word');
         ts_lexize
-----
{word,syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=false,
MATCHSYNONYMS=true);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
         ts_lexize
-----
{syn1,syn2,syn3}
```

```
mydb# ALTER TEXT SEARCH DICTIONARY xsyn (RULES='my_rules', KEEPORIG=true,
MATCHORIG=false, KEEPSYNONYMS=false);
ALTER TEXT SEARCH DICTIONARY
```

```
mydb=# SELECT ts_lexize('xsyn', 'syn1');
         ts_lexize
-----
{word}
```

Real-world usage will involve including it in a text search configuration as described in [Chapter 12](#). That might look like this:

```
ALTER TEXT SEARCH CONFIGURATION english
  ALTER MAPPING FOR word, asciiword WITH xsyn, english_stem;
```

F.14. dump_stat

The `dump_stat` module provides functions that allow you to backup and recover the contents of the `pg_statistic` table. When performing a dump/restore, you can use `dump_stat` to migrate the original statistics to the new server instead of running the `ANALYZE` command for the whole database cluster, which can significantly reduce downtime for large databases. The `dump_statistic` function generates `INSERT` statements which can later be applied to a compatible database. To successfully restore statistical data, you must install the extension on both the original and the recipient servers since these statements rely on the provided `dump_stat` functions.

Note that the definition of the `pg_statistic` table might change occasionally, which means that generated dump might be incompatible with future releases of Postgres Pro.

F.14.1. Installation

The `dump_stat` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the `CREATE EXTENSION` command to enable `dump_stat`, as follows:

```
CREATE EXTENSION dump_stat;
```

F.14.2. Functions

`anyarray_to_text(array anyarray)` returns text

Returns the given array as text.

`dump_statistic()` returns setof text

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic`, excluding the ones that contain statistical data for tables in the `information_schema` and `pg_catalog` schemas.

The `INSERT` statement takes form of

```
WITH upsert as (
  UPDATE pg_catalog.pg_statistic SET column_name = expression [, ...]
  WHERE starelid = t_relname::regclass
    AND to_attnum(t_relname, staattnum) = t_attnum
    AND to_atttype(t_relname, staattnum) = t_atttype
    AND stainherit = t_stainherit
  RETURNING *)
ins as (
  SELECT expression [, ...]
  WHERE NOT EXISTS (SELECT * FROM upsert)
    AND to_attnum(t_relname, t_attnum) IS NOT NULL
    AND to_atttype(t_relname, t_attnum) = t_atttype)
INSERT INTO pg_catalog.pg_statistic SELECT * FROM ins;
```

where *expression* can be one of:

```
array_in(array_text, type_name::regtype::oid, -1)
value::type_name
```

To save the produced statements, redirect the `psql` output into a file using standard `psql` options. For details on the available `psql` options, see [psql](#). Meta-commands starting with a backslash are not supported.

For example, to save statistics for the `dbname` database into a `dump_stat.sql` file, run:

```
$ psql -XAtq -c "SELECT dump_statistic()" dbname > dump_stat.sql
```

`dump_statistic(schema_name text)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to some table in the `schema_name` schema.

`dump_statistic(schema_name text, table_name text)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that relates to the specified `schema_name.table_name` table.

`dump_statistic(relation regclass)` returns `setof text`

`dump_statistic` dumps the contents of the `pg_statistic` system catalog. It produces an `INSERT` statement per each tuple of the `pg_statistic` that contains statistical data for the specified `relation`.

`to_schema_qualified_operator(opid oid)` returns `text`

Fetches the schema-qualified operator name by operator id `opid`. For example:

```
test=# SELECT to_schema_qualified_operator('+(int,int)::regoperator);
         to_schema_qualified_operator
-----
pg_catalog.+(pg_catalog.int4, pg_catalog.int4)
(1 row)
```

`to_schema_qualified_type(typid oid)` returns `text`

Fetches the schema-qualified type name by type id `typid`.

`to_schema_qualified_relation(relid oid)` returns `text`

Fetches the schema-qualified relation name by relation id `relid`.

`anyarray_elemtype(arr anyarray)` returns `oid`

Returns the element type of the given array as `oid`. For example:

```
test=# SELECT anyarray_elemtype(array_in('{1,2,3}', 'int'::regtype, -1));
         anyarray_elemtype
-----
                        23
(1 row)
```

`to_attname(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the column name as `text`.

`to_attnum(relation regclass, col text)` returns `int2`

Given a relation name `relation` and a column name `col`, returns the column number as `int2`.

`to_atttype(relation regclass, col text)` returns `text`

Given a relation name `relation` and a column name `col`, returns the schema-qualified column type as `text`.

`to_atttype(relation regclass, colnum int2)` returns `text`

Given a relation name `relation` and a column number `colnum`, returns the schema-qualified column type as `text`.

`to_namespace(nsp text)` returns `oid`

`to_namespace` duplicates the behavior of the cast to the `regnamespace` type, which is not present in the PostgreSQL 9.4 release (and prior releases). This function returns the `oid` of the given schema.

`get_namespace(relation oid)` returns `oid`

`get_namespace` returns the schema of the given relation as `oid`.

F.15. earthdistance

The `earthdistance` module provides two different approaches to calculating great circle distances on the surface of the Earth. The one described first depends on the `cube` module. The second one is based on the built-in `point` data type, using longitude and latitude for the coordinates.

In this module, the Earth is assumed to be perfectly spherical. (If that's too inaccurate for you, you might want to look at the [PostGIS](#) project.)

The `cube` module must be installed before `earthdistance` can be installed (although you can use the `CASCADE` option of `CREATE EXTENSION` to install both in one command).

Caution

It is strongly recommended that `earthdistance` and `cube` be installed in the same schema, and that that schema be one for which `CREATE` privilege has not been and will not be granted to any untrusted users. Otherwise there are installation-time security hazards if `earthdistance`'s schema contains objects defined by a hostile user. Furthermore, when using `earthdistance`'s functions after installation, the entire search path should contain only trusted schemas.

F.15.1. Cube-Based Earth Distances

Data is stored in cubes that are points (both corners are the same) using 3 coordinates representing the `x`, `y`, and `z` distance from the center of the Earth. A domain `earth` over `cube` is provided, which includes constraint checks that the value meets these restrictions and is reasonably close to the actual surface of the Earth.

The radius of the Earth is obtained from the `earth()` function. It is given in meters. But by changing this one function you can change the module to use some other units, or to use a different value of the radius that you feel is more appropriate.

This package has applications to astronomical databases as well. Astronomers will probably want to change `earth()` to return a radius of `180/pi()` so that distances are in degrees.

Functions are provided to support input in latitude and longitude (in degrees), to support output of latitude and longitude, to calculate the great circle distance between two points and to easily specify a bounding box usable for index searches.

The provided functions are shown in [Table F.9](#).

Table F.9. Cube-Based Earthdistance Functions

Function	Description
<code>earth () → float8</code>	Returns the assumed radius of the Earth.
<code>sec_to_gc (float8) → float8</code>	Converts the normal straight line (secant) distance between two points on the surface of the Earth to the great circle distance between them.
<code>gc_to_sec (float8) → float8</code>	Converts the great circle distance between two points on the surface of the Earth to the normal straight line (secant) distance between them.
<code>ll_to_earth (float8, float8) → earth</code>	

Function	Description
	Returns the location of a point on the surface of the Earth given its latitude (argument 1) and longitude (argument 2) in degrees.
<code>latitude (earth) → float8</code>	Returns the latitude in degrees of a point on the surface of the Earth.
<code>longitude (earth) → float8</code>	Returns the longitude in degrees of a point on the surface of the Earth.
<code>earth_distance (earth, earth) → float8</code>	Returns the great circle distance between two points on the surface of the Earth.
<code>earth_box (earth, float8) → cube</code>	Returns a box suitable for an indexed search using the <code>cube @></code> operator for points within a given great circle distance of a location. Some points in this box are further than the specified great circle distance from the location, so a second check using <code>earth_distance</code> should be included in the query.

F.15.2. Point-Based Earth Distances

The second part of the module relies on representing Earth locations as values of type `point`, in which the first component is taken to represent longitude in degrees, and the second component is taken to represent latitude in degrees. Points are taken as (longitude, latitude) and not vice versa because longitude is closer to the intuitive idea of x-axis and latitude to y-axis.

A single operator is provided, shown in [Table F.10](#).

Table F.10. Point-Based Earthdistance Operators

Operator	Description
<code>point <@> point → float8</code>	Computes the distance in statute miles between two points on the Earth's surface.

Note that unlike the `cube`-based part of the module, units are hardwired here: changing the `earth()` function will not affect the results of this operator.

One disadvantage of the longitude/latitude representation is that you need to be careful about the edge conditions near the poles and near +/- 180 degrees of longitude. The `cube`-based representation avoids these discontinuities.

F.16. fasttrun

The `fasttrun` module provides transaction unsafe function to truncate temporary tables without growing `pg_class` size.

This module is required for 1C Enterprise support.

Fast truncate operation is not transactional, so its results cannot be rolled back and become immediately visible in all sessions regardless of isolation level.

F.16.1. Function

There is a function call example:

```
select fasttruncate('TABLE_NAME');
```

F.16.2. Test example

For tests you can use this example:

```
create or replace function f() returns void as $$
begin
  for i in 1..1000
    loop
      PERFORM fasttruncate('tt1');
    end loop;
end;
$$ language plpgsql;
```

F.16.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.17. file_fdw

The `file_fdw` module provides the foreign-data wrapper `file_fdw`, which can be used to access data files in the server's file system, or to execute programs on the server and read their output. The data file or program output must be in a format that can be read by `COPY FROM`; see [COPY](#) for details. Access to data files is currently read-only.

A foreign table created using this wrapper can have the following options:

`filename`

Specifies the file to be read. Relative paths are relative to the data directory. Either `filename` or `program` must be specified, but not both.

`program`

Specifies the command to be executed. The standard output of this command will be read as though `COPY FROM PROGRAM` were used. Either `program` or `filename` must be specified, but not both.

`format`

Specifies the data format, the same as `COPY`'s `FORMAT` option.

`header`

Specifies whether the data has a header line, the same as `COPY`'s `HEADER` option.

`delimiter`

Specifies the data delimiter character, the same as `COPY`'s `DELIMITER` option.

`quote`

Specifies the data quote character, the same as `COPY`'s `QUOTE` option.

`escape`

Specifies the data escape character, the same as `COPY`'s `ESCAPE` option.

`null`

Specifies the data null string, the same as `COPY`'s `NULL` option.

`encoding`

Specifies the data encoding, the same as `COPY`'s `ENCODING` option.

Note that while `COPY` allows options such as `HEADER` to be specified without a corresponding value, the foreign table option syntax requires a value to be present in all cases. To activate `COPY` options typically written without a value, you can pass the value `TRUE`, since all such options are Booleans.

A column of a foreign table created using this wrapper can have the following options:

`force_not_null`

This is a Boolean option. If true, it specifies that values of the column should not be matched against the null string (that is, the table-level `null` option). This has the same effect as listing the column in COPY's `FORCE_NOT_NULL` option.

`force_null`

This is a Boolean option. If true, it specifies that values of the column which match the null string are returned as `NULL` even if the value is quoted. Without this option, only unquoted values matching the null string are returned as `NULL`. This has the same effect as listing the column in COPY's `FORCE_NULL` option.

COPY's `FORCE_QUOTE` option is currently not supported by `file_fdw`.

These options can only be specified for a foreign table or its columns, not in the options of the `file_fdw` foreign-data wrapper, nor in the options of a server or user mapping using the wrapper.

Changing table-level options requires being a superuser or having the privileges of the default role `pg_read_server_files` (to use a filename) or the default role `pg_execute_server_program` (to use a program), for security reasons: only certain users should be able to control which file is read or which program is run. In principle regular users could be allowed to change the other options, but that's not supported at present.

When specifying the `program` option, keep in mind that the option string is executed by the shell. If you need to pass any arguments to the command that come from an untrusted source, you must be careful to strip or escape any characters that might have special meaning to the shell. For security reasons, it is best to use a fixed command string, or at least avoid passing any user input in it.

For a foreign table using `file_fdw`, `EXPLAIN` shows the name of the file to be read or program to be run. For a file, unless `COSTS OFF` is specified, the file size (in bytes) is shown as well.

Example F.3. Create a Foreign Table for Postgres Pro CSV Logs

One of the obvious uses for `file_fdw` is to make the Postgres Pro activity log available as a table for querying. To do this, first you must be [logging to a CSV file](#), which here we will call `pglog.csv`. First, install `file_fdw` as an extension:

```
CREATE EXTENSION file_fdw;
```

Then create a foreign server:

```
CREATE SERVER pglog FOREIGN DATA WRAPPER file_fdw;
```

Now you are ready to create the foreign data table. Using the `CREATE FOREIGN TABLE` command, you will need to define the columns for the table, the CSV file name, and its format:

```
CREATE FOREIGN TABLE pglog (  
    log_time timestamp(3) with time zone,  
    user_name text,  
    database_name text,  
    process_id integer,  
    connection_from text,  
    session_id text,  
    session_line_num bigint,  
    command_tag text,  
    session_start_time timestamp with time zone,  
    virtual_transaction_id text,  
    transaction_id bigint,  
    error_severity text,  
    sql_state_code text,  
    message text,  
    detail text,
```

```
hint text,  
internal_query text,  
internal_query_pos integer,  
context text,  
query text,  
query_pos integer,  
location text,  
application_name text,  
backend_type text  
) SERVER pglog  
OPTIONS ( filename 'log/pglog.csv', format 'csv' );
```

That's it — now you can query your log directly. In production, of course, you would need to define some way to deal with log rotation.

F.18. fulleq

The `fulleq` module provides additional equivalence operator for compatibility with Microsoft SQL Server.

This module is required for 1C Enterprise support.

F.18.1. Overview

The Postgres Pro equivalence operator is defined to return NULL when both operands are NULLs. However, the Microsoft SQL Servers family traditionally defines other semantic for equivalence operator, where operator returns TRUE in the case of both nulled operands. This module provides such operator with MS SQL semantic.

F.18.2. Operator `fulleq`

The `==` operator is defined for the following data types:

- `bool`
- `bytea`
- `char`
- `name`
- `int2`
- `int4`
- `int8`
- `int2vector`
- `text`
- `oid`
- `xid`
- `cid`
- `oidvector`
- `float4`
- `float8`
- `abstime`
- `reltime`
- `macaddr`
- `inet`
- `cidr`

- varchar
- date
- time
- timestamp
- timestamptz
- interval
- timetz

F.18.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.19. fuzzystmatch

The `fuzzystmatch` module provides several functions to determine similarities and distance between strings.

Caution

At present, the `soundex`, `metaphone`, `dmetaphone`, and `dmetaphone_alt` functions do not work well with multibyte encodings (such as UTF-8).

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.19.1. Soundex

The Soundex system is a method of matching similar-sounding names by converting them to the same code. It was initially used by the United States Census in 1880, 1900, and 1910. Note that Soundex is not very useful for non-English names.

The `fuzzystmatch` module provides two functions for working with Soundex codes:

```
soundex(text) returns text
difference(text, text) returns int
```

The `soundex` function converts a string to its Soundex code. The `difference` function converts two strings to their Soundex codes and then reports the number of matching code positions. Since Soundex codes have four characters, the result ranges from zero to four, with zero being no match and four being an exact match. (Thus, the function is misnamed — `similarity` would have been a better name.)

Here are some usage examples:

```
SELECT soundex('hello world!');

SELECT soundex('Anne'), soundex('Ann'), difference('Anne', 'Ann');
SELECT soundex('Anne'), soundex('Andrew'), difference('Anne', 'Andrew');
SELECT soundex('Anne'), soundex('Margaret'), difference('Anne', 'Margaret');

CREATE TABLE s (nm text);

INSERT INTO s VALUES ('john');
INSERT INTO s VALUES ('joan');
INSERT INTO s VALUES ('wobbly');
INSERT INTO s VALUES ('jack');
```

```
SELECT * FROM s WHERE soundex(nm) = soundex('john');
```

```
SELECT * FROM s WHERE difference(s.nm, 'john') > 2;
```

F.19.2. Levenshtein

This function calculates the Levenshtein distance between two strings:

```
levenshtein(text source, text target, int ins_cost, int del_cost, int sub_cost) returns  
int
```

```
levenshtein(text source, text target) returns int
```

```
levenshtein_less_equal(text source, text target, int ins_cost, int del_cost, int  
sub_cost, int max_d) returns int
```

```
levenshtein_less_equal(text source, text target, int max_d) returns int
```

Both `source` and `target` can be any non-null string, with a maximum of 255 characters. The cost parameters specify how much to charge for a character insertion, deletion, or substitution, respectively. You can omit the cost parameters, as in the second version of the function; in that case they all default to 1.

`levenshtein_less_equal` is an accelerated version of the Levenshtein function for use when only small distances are of interest. If the actual distance is less than or equal to `max_d`, then `levenshtein_less_equal` returns the correct distance; otherwise it returns some value greater than `max_d`. If `max_d` is negative then the behavior is the same as `levenshtein`.

Examples:

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL');  
levenshtein
```

```
-----  
                2  
(1 row)
```

```
test=# SELECT levenshtein('GUMBO', 'GAMBOL', 2, 1, 1);  
levenshtein
```

```
-----  
                3  
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 2);  
levenshtein_less_equal
```

```
-----  
                3  
(1 row)
```

```
test=# SELECT levenshtein_less_equal('extensive', 'exhaustive', 4);  
levenshtein_less_equal
```

```
-----  
                4  
(1 row)
```

F.19.3. Metaphone

Metaphone, like Soundex, is based on the idea of constructing a representative code for an input string. Two strings are then deemed similar if they have the same codes.

This function calculates the metaphone code of an input string:

```
metaphone(text source, int max_output_length) returns text
```

`source` has to be a non-null string with a maximum of 255 characters. `max_output_length` sets the maximum length of the output metaphone code; if longer, the output is truncated to this length.

Example:

```
test=# SELECT metaphone('GUMBO', 4);
 metaphone
-----
 KM
(1 row)
```

F.19.4. Double Metaphone

The Double Metaphone system computes two “sounds like” strings for a given input string — a “primary” and an “alternate”. In most cases they are the same, but for non-English names especially they can be a bit different, depending on pronunciation. These functions compute the primary and alternate codes:

```
dmetaphone(text source) returns text
dmetaphone_alt(text source) returns text
```

There is no length limit on the input strings.

Example:

```
test=# SELECT dmetaphone('gumbo');
 dmetaphone
-----
 KMP
(1 row)
```

F.20. hstore

This module implements the `hstore` data type for storing sets of key/value pairs within a single Postgres Pro value. This can be useful in various scenarios, such as rows with many attributes that are rarely examined, or semi-structured data. Keys and values are simply text strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.20.1. hstore External Representation

The text representation of an `hstore`, used for input and output, includes zero or more `key => value` pairs separated by commas. Some examples:

```
k => v
foo => bar, baz => whatever
"1-a" => "anything at all"
```

The order of the pairs is not significant (and may not be reproduced on output). Whitespace between pairs or around the `=>` sign is ignored. Double-quote keys and values that include whitespace, commas, `=`s or `>`s. To include a double quote or a backslash in a key or value, escape it with a backslash.

Each key in an `hstore` is unique. If you declare an `hstore` with duplicate keys, only one will be stored in the `hstore` and there is no guarantee as to which will be kept:

```
SELECT 'a=>1,a=>2'::hstore;
 hstore
-----
 "a"=>"1"
```

A value (but not a key) can be an SQL `NULL`. For example:

```
key => NULL
```

The `NULL` keyword is case-insensitive. Double-quote the `NULL` to treat it as the ordinary string “NULL”.

Note

Keep in mind that the `hstore` text format, when used for input, applies *before* any required quoting or escaping. If you are passing an `hstore` literal via a parameter, then no additional processing is needed. But if you're passing it as a quoted literal constant, then any single-quote characters and (depending on the setting of the `standard_conforming_strings` configuration parameter) backslash characters need to be escaped correctly. See [Section 4.1.2.1](#) for more on the handling of string constants.

On output, double quotes always surround keys and values, even when it's not strictly necessary.

F.20.2. hstore Operators and Functions

The operators provided by the `hstore` module are shown in [Table F.11](#), the functions in [Table F.12](#).

Table F.11. hstore Operators

Operator	Description	Example(s)
<code>hstore -> text → text</code>	Returns value associated with given key, or NULL if not present.	<code>'a=>x, b=>y'::hstore -> 'a' → x</code>
<code>hstore -> text[] → text[]</code>	Returns values associated with given keys, or NULL if not present.	<code>'a=>x, b=>y, c=>z'::hstore -> ARRAY['c','a'] → {'z','x'}</code>
<code>hstore hstore → hstore</code>	Concatenates two hstores.	<code>'a=>b, c=>d'::hstore 'c=>x, d=>q'::hstore → "a"=>"b", "c"=>"x", "d"=>"q"</code>
<code>hstore ? text → boolean</code>	Does hstore contain key?	<code>'a=>1'::hstore ? 'a' → t</code>
<code>hstore ?& text[] → boolean</code>	Does hstore contain all the specified keys?	<code>'a=>1,b=>2'::hstore ?& ARRAY['a','b'] → t</code>
<code>hstore ? text[] → boolean</code>	Does hstore contain any of the specified keys?	<code>'a=>1,b=>2'::hstore ? ARRAY['b','c'] → t</code>
<code>hstore @> hstore → boolean</code>	Does left operand contain right?	<code>'a=>b, b=>1, c=>NULL'::hstore @> 'b=>1' → t</code>
<code>hstore <@ hstore → boolean</code>	Is left operand contained in right?	<code>'a=>c'::hstore <@ 'a=>b, b=>1, c=>NULL' → f</code>
<code>hstore - text → hstore</code>	Deletes key from left operand.	<code>'a=>1, b=>2, c=>3'::hstore - 'b'::text → "a"=>"1", "c"=>"3"</code>
<code>hstore - text[] → hstore</code>	Deletes keys from left operand.	

Operator	Description	Example(s)
		'a=>1, b=>2, c=>3'::hstore - ARRAY['a','b'] → "c"=>"3"
hstore - hstore → hstore	Deletes pairs from left operand that match pairs in the right operand.	'a=>1, b=>2, c=>3'::hstore - 'a=>4, b=>2'::hstore → "a"=>"1", "c"=>"3"
anyelement #= hstore → anyelement	Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	ROW(1,3) #= 'f1=>11'::hstore → (11,3)
%% hstore → text[]	Converts hstore to an array of alternating keys and values.	%% 'a=>foo, b=>bar'::hstore → {a,foo,b,bar}
%# hstore → text[]	Converts hstore to a two-dimensional key/value array.	%# 'a=>foo, b=>bar'::hstore → {{a,foo},{b,bar}}

Note

Prior to PostgreSQL 8.2, the containment operators @> and <@ were called @ and ~, respectively. These names are still available, but are deprecated and will eventually be removed. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!

Table F.12. hstore Functions

Function	Description	Example(s)
hstore (record) → hstore	Constructs an hstore from a record or row.	hstore(ROW(1,2)) → "f1"=>"1", "f2"=>"2"
hstore (text[]) → hstore	Constructs an hstore from an array, which may be either a key/value array, or a two-dimensional array.	hstore(ARRAY['a','1','b','2']) → "a"=>"1", "b"=>"2" hstore(ARRAY[['c','3'],['d','4']]) → "c"=>"3", "d"=>"4"
hstore (text[], text[]) → hstore	Constructs an hstore from separate key and value arrays.	hstore(ARRAY['a','b'], ARRAY['1','2']) → "a"=>"1", "b"=>"2"
hstore (text, text) → hstore	Makes a single-item hstore.	hstore('a', 'b') → "a"=>"b"
akeys (hstore) → text[]	Extracts an hstore's keys as an array.	akeys('a=>1,b=>2') → {a,b}
skeys (hstore) → setof text	Extracts an hstore's keys as a set.	

Function	Description	Example(s)
		<pre>skeys('a=>1,b=>2') →</pre> <pre>a</pre> <pre>b</pre>
<code>avals (hstore)</code>	→ <code>text []</code> Extracts an <code>hstore</code> 's values as an array.	<pre>avals('a=>1,b=>2') → {1,2}</pre>
<code>svals (hstore)</code>	→ <code>setof text</code> Extracts an <code>hstore</code> 's values as a set.	<pre>svals('a=>1,b=>2') →</pre> <pre>1</pre> <pre>2</pre>
<code>hstore_to_array (hstore)</code>	→ <code>text []</code> Extracts an <code>hstore</code> 's keys and values as an array of alternating keys and values.	<pre>hstore_to_array('a=>1,b=>2') → {a,1,b,2}</pre>
<code>hstore_to_matrix (hstore)</code>	→ <code>text []</code> Extracts an <code>hstore</code> 's keys and values as a two-dimensional array.	<pre>hstore_to_matrix('a=>1,b=>2') → {{a,1},{b,2}}</pre>
<code>hstore_to_json (hstore)</code>	→ <code>json</code> Converts an <code>hstore</code> to a <code>json</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>json</code> .	<pre>hstore_to_json('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</pre>
<code>hstore_to_jsonb (hstore)</code>	→ <code>jsonb</code> Converts an <code>hstore</code> to a <code>jsonb</code> value, converting all non-null values to JSON strings. This function is used implicitly when an <code>hstore</code> value is cast to <code>jsonb</code> .	<pre>hstore_to_jsonb('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": "1", "b": "t", "c": null, "d": "12345", "e": "012345", "f": "1.234", "g": "2.345e+4"}</pre>
<code>hstore_to_json_loose (hstore)</code>	→ <code>json</code> Converts an <code>hstore</code> to a <code>json</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<pre>hstore_to_json_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>
<code>hstore_to_jsonb_loose (hstore)</code>	→ <code>jsonb</code> Converts an <code>hstore</code> to a <code>jsonb</code> value, but attempts to distinguish numerical and Boolean values so they are unquoted in the JSON.	<pre>hstore_to_jsonb_loose('"a key"=>1, b=>t, c=>null, d=>12345, e=>012345, f=>1.234, g=>2.345e+4') → {"a key": 1, "b": true, "c": null, "d": 12345, "e": "012345", "f": 1.234, "g": 2.345e+4}</pre>
<code>slice (hstore, text [])</code>	→ <code>hstore</code> Extracts a subset of an <code>hstore</code> containing only the specified keys.	<pre>slice('a=>1,b=>2,c=>3'::hstore, ARRAY['b','c','x']) → "b"=>"2", "c"=>"3"</pre>

Function	Description	Example(s)						
<code>each (hstore) → setof record (key text, value text)</code>	Extracts an hstore's keys and values as a set of records.	<code>select * from each('a=>1,b=>2') →</code> <table><tr><th>key</th><th>value</th></tr><tr><td>a</td><td>1</td></tr><tr><td>b</td><td>2</td></tr></table>	key	value	a	1	b	2
key	value							
a	1							
b	2							
<code>exist (hstore, text) → boolean</code>	Does hstore contain key?	<code>exist('a=>1', 'a') → t</code>						
<code>defined (hstore, text) → boolean</code>	Does hstore contain a non-NULL value for key?	<code>defined('a=>NULL', 'a') → f</code>						
<code>delete (hstore, text) → hstore</code>	Deletes pair with matching key.	<code>delete('a=>1,b=>2', 'b') → "a"=>"1"</code>						
<code>delete (hstore, text[]) → hstore</code>	Deletes pairs with matching keys.	<code>delete('a=>1,b=>2,c=>3', ARRAY['a','b']) → "c"=>"3"</code>						
<code>delete (hstore, hstore) → hstore</code>	Deletes pairs matching those in the second argument.	<code>delete('a=>1,b=>2', 'a=>4,b=>2'::hstore) → "a"=>"1"</code>						
<code>populate_record (anyelement, hstore) → anyelement</code>	Replaces fields in the left operand (which must be a composite type) with matching values from hstore.	<code>populate_record(ROW(1,2), 'f1=>42'::hstore) → (42,2)</code>						

F.20.3. Indexes

hstore has GiST and GIN index support for the @>, ?, ?& and ?| operators. For example:

```
CREATE INDEX hidx ON testhstore USING GIST (h);
```

```
CREATE INDEX hidx ON testhstore USING GIN (h);
```

`gist_hstore_ops` GiST opclass approximates a set of key/value pairs as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX hidx ON testhstore USING GIST (h gist_hstore_ops(siglen=32));
```

hstore also supports btree or hash indexes for the = operator. This allows hstore columns to be declared UNIQUE, or to be used in GROUP BY, ORDER BY or DISTINCT expressions. The sort ordering for hstore values is not particularly useful, but these indexes may be useful for equivalence lookups. Create indexes for = comparisons as follows:

```
CREATE INDEX hidx ON testhstore USING BTREE (h);
```

```
CREATE INDEX hidx ON testhstore USING HASH (h);
```

F.20.4. Examples

Add a key, or update an existing key with a new value:

```
UPDATE tab SET h = h || hstore('c', '3');
```

Delete a key:

```
UPDATE tab SET h = delete(h, 'k1');
```

Convert a record to an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');
```

```
SELECT hstore(t) FROM test AS t;
           hstore
-----
"col1"=>"123", "col2"=>"foo", "col3"=>"bar"
(1 row)
```

Convert an hstore to a predefined record type:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);

SELECT * FROM populate_record(null::test,
                               '"col1"=>"456", "col2"=>"zzz"');
 col1 | col2 | col3
-----+-----+-----
  456 | zzz  |
(1 row)
```

Modify an existing record using the values from an hstore:

```
CREATE TABLE test (col1 integer, col2 text, col3 text);
INSERT INTO test VALUES (123, 'foo', 'bar');

SELECT (r).* FROM (SELECT t #= '"col3"=>"baz"' AS r FROM test t) s;
 col1 | col2 | col3
-----+-----+-----
  123 | foo  | baz
(1 row)
```

F.20.5. Statistics

The `hstore` type, because of its intrinsic liberality, could contain a lot of different keys. Checking for valid keys is the task of the application. The following examples demonstrate several techniques for checking keys and obtaining statistics.

Simple example:

```
SELECT * FROM each('aaa=>bq, b=>NULL, ""=>1');
```

Using a table:

```
SELECT (each(h)).key, (each(h)).value INTO stat FROM testhstore;
```

Online statistics:

```
SELECT key, count(*) FROM
```

```
(SELECT (each(h)).key FROM testhstore) AS stat
GROUP BY key
ORDER BY count DESC, key;
```

key		count
line		883
query		207
pos		203
node		202
space		197
status		195
public		194
title		190
org		189

.....

F.20.6. Compatibility

As of PostgreSQL 9.0, `hstore` uses a different internal representation than previous versions. This presents no obstacle for dump/restore upgrades since the text representation (used in the dump) is unchanged.

In the event of a binary upgrade, upward compatibility is maintained by having the new code recognize old-format data. This will entail a slight performance penalty when processing data that has not yet been modified by the new code. It is possible to force an upgrade of all values in a table column by doing an `UPDATE` statement as follows:

```
UPDATE tablename SET hstorecol = hstorecol || '';
```

Another way to do it is:

```
ALTER TABLE tablename ALTER hstorecol TYPE hstore USING hstorecol || '';
```

The `ALTER TABLE` method requires an `ACCESS EXCLUSIVE` lock on the table, but does not result in bloating the table with old row versions.

F.20.7. Transforms

Additional extensions are available that implement transforms for the `hstore` type for the languages PL/Perl and PL/Python. The extensions for PL/Perl are called `hstore_plperl` and `hstore_plperl_u`, for trusted and untrusted PL/Perl. If you install these transforms and specify them when creating a function, `hstore` values are mapped to Perl hashes. The extensions for PL/Python are called `hstore_plpythonu`, `hstore_plpython2u`, and `hstore_plpython3u` (see [Section 47.1](#) for the PL/Python naming convention). If you use them, `hstore` values are mapped to Python dictionaries.

Caution

It is strongly recommended that the transform extensions be installed in the same schema as `hstore`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.20.8. Authors

Oleg Bartunov <oleg@sai.msu.su>, Moscow, Moscow University, Russia

F.21. Hunspell Dictionaries Modules

These modules provide Hunspell dictionaries for various languages. Upon installation of the module into database using `CREATE EXTENSION` command, text search dictionary and configuration objects in the public schema appear.

Table F.13. Modules

Language	Extension name	Dictionary name	Configuration name
American English	hunspell_en_us	english_hunspell	english_hunspell
Dutch	hunspell_nl_nl	dutch_hunspell	dutch_hunspell
French	hunspell_fr	french_hunspell	french_hunspell
Russian	hunspell_ru_ru	russian_hunspell	russian_hunspell

F.21.1. Examples

Text search objects will be created after installation of a dictionary module. We can test created configuration:

```
SELECT * FROM ts_debug('english_hunspell', 'abilities');
  alias  | description | token | dictionaries |
  dictionary | lexemes
-----+-----+-----+-----
+-----+-----+
asciword | Word, all ASCII | abilities | {english_hunspell,english_stem} |
english_hunspell | {ability}
(1 row)
```

Or you can create your own text search configuration. For example, with the created dictionaries and with the `Snowball` dictionary you can create mixed russian-english configuration:

```
CREATE TEXT SEARCH CONFIGURATION russian_en (
  COPY = simple
);

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR asciword, asciihword, hword_asciipart
  WITH english_hunspell, english_stem;

ALTER TEXT SEARCH CONFIGURATION russian_en
  ALTER MAPPING FOR word, hword, hword_part
  WITH russian_hunspell, russian_stem;
```

You can create mixed dictionaries only for languages with different alphabets. If languages have similar alphabets then Postgres Pro can not decide which dictionary should be used.

A text search configuration which is created with a dictionary module is ready to use. For example, in this text you can search some words:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal');
  to_tsvector
-----
'animal':7 'blue':2 'large':6 'whale':3
(1 row)
```

Search query might looks like this:

```
SELECT to_tsvector('english_hunspell', 'The blue whale is the largest animal')
  @@ to_tsquery('english_hunspell', 'large & whale');
```

```
?column?
-----
t
(1 row)
```

With this configurations you can search a text using GIN or GIST indexes. For example, there is a table with GIN index:

```
CREATE TABLE table1 (t varchar);
INSERT INTO table1 VALUES ('The blue whale is the largest animal');
CREATE INDEX t_idx ON table1 USING GIN (to_tsvector('english_hunspell', "t"));
```

For this table you can execute the following query:

```
SELECT * FROM table1 where to_tsvector('english_hunspell', t)
@@ to_tsquery('english_hunspell', 'blue & animal');
           t
-----
The blue whale is the largest animal
(1 row)
```

F.22. in_memory

The `in_memory` extension enables you to store data in Postgres Pro shared memory using in-memory tables implemented via foreign data wrappers (FDW).

Note

This extension cannot be used together with prepared transactions or while built-in connection pooling is enabled.

In-memory tables are *index-organized* — table rows are stored in leaf pages of the B-tree index defined on the primary key for the table. This solution offers the following benefits:

- Fast random access on the primary key. This can result in significant performance benefits when working with data that requires a very high read and write access rate, especially on multi-core systems.
- Effective space usage. There is no primary key duplication as all data is stored directly in the index.

In-memory tables support transactions, including savepoints. However, the data in such tables is stored only while the server is running. Once the server is shut down, all in-memory data gets truncated. When using in-memory tables, you should also take into account the following restrictions:

- Persistence, WAL, and data replication are currently not supported for in-memory tables.
- Secondary indexes are not supported.
- Isolation levels are supported up to `REPEATABLE READ`. `SERIALIZABLE` isolation level is not supported. `REPEATABLE READ` level is used instead.
- In-memory tables do not support TOAST or any other mechanism for storing big tuples. Since the in-memory page size is 1 kB, and the B-tree index requires at least three tuples in a page, the maximum row length is limited to 304 bytes.
- When a row is deleted from an in-memory table, the corresponding data page is not freed. See [Section F.22.2.3](#) for details.

F.22.1. Installation and Setup

To enable in-memory tables for your cluster:

1. Make sure that the `postgres_fdw` module is enabled.

2. Add the `in_memory` value to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'in_memory'
```

3. Create the `in_memory` extension using the following statement:

```
CREATE EXTENSION in_memory;
```

As a result, the `in_memory` foreign server is created, and a separate shared memory pool is allocated for in-memory tables, with pre-created pages for storing in-memory data. For in-memory tables, smaller locality is required for effective memory access, as compared to hard drives or SSD, so in-memory page size is 1 kB only. Once the extension is created, you can start using in-memory tables as explained in [Section F.22.2](#).

Tip

If required, you can increase the memory size allocated for in-memory tables. For details, see [Section F.22.2.6](#).

F.22.2. Usage

F.22.2.1. Creating In-Memory Tables

To add an in-memory table to your database, create a foreign table on the `in_memory` server, using the regular [CREATE FOREIGN TABLE](#) syntax. By default, a unique B-tree index is built upon the first column, in the ascending order. If required, you can use the `INDICES` option in the `OPTIONS` clause to define a different B-tree index structure, as follows:

```
OPTIONS ( INDICES '[ UNIQUE ] {column [ COLLATE collation ] [ASC | DESC] } [, ... ]' )
```

where *column* is the column to include into the B-tree index, and *collation* is the name of the collation to use for this column. You can specify up to eight arbitrary columns separated by commas, with sorting options defined for each of these columns (`COLLATE`, `ASC/DESC`). The `UNIQUE` declares the created index unique, reiterating the default behavior.

All columns to be used in the B-tree index must be of a type for which the default B-tree operator class is available. For details on operator classes, see [Section 11.10](#).

Examples

Create an in-memory table `blog_views` to store statistics on blog views based on blog post IDs, with the unique B-tree index built upon the first column, in the ascending order:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
OPTIONS (INDICES 'UNIQUE (id)');
```

Define the B-tree index on the `id` and `author` columns, with the `author` values sorted in the ascending order using `"ru_RU"` collation:

```
CREATE FOREIGN TABLE blog_views
(
    id int8 NOT NULL,
    author text,
    views bigint NOT NULL
) SERVER in_memory
```

```
OPTIONS (INDICES '(id, author COLLATE "ru_RU" ASC)');
```

F.22.2.2. Running Queries on In-Memory Tables

Once an in-memory table is created, you can run all the main DML operations on this table: `SELECT`, `INSERT`, `UPDATE`, `DELETE`.

If you use the primary key as the scan qualifier when running queries, a key lookup or range scan is performed. Otherwise, a full index scan is required.

Examples

Fill the `blog_views` table with initial zero values for initial ten blog posts:

```
postgres=# INSERT INTO blog_views (SELECT id, 0 FROM generate_series(1, 10) AS id);
```

Increment the view count for a couple of posts and display the result:

```
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 1
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 1;
UPDATE 2
postgres=# UPDATE blog_views SET views = views + 1 WHERE id = 2;
UPDATE 1
postgres=# SELECT * FROM blog_views WHERE id = 1 OR id = 2;
 id | views
----+-----
  1 |    2
  2 |    1
(2 rows)
```

Check planning and execution costs for a query that only requires a primary key lookup:

```
postgres=# EXPLAIN ANALYZE SELECT * FROM blog_views WHERE id = 1;
               QUERY PLAN
-----
Foreign Scan on blog_views  (cost=0.02..0.03 rows=1 width=16)
(actual time=0.013..0.014 rows=1 loops=1)
  Pk conds: (id = 1)
Planning time: 0.060 ms
Execution time: 0.035 ms
(4 rows)
```

Check the costs of calculating the sum of all views, which requires a full index scan:

```
postgres=# EXPLAIN ANALYZE SELECT SUM(views) FROM blog_views;
               QUERY PLAN
-----
Aggregate  (cost=1.62..1.63 rows=1 width=32)
(actual time=0.323..0.323 rows=1 loops=1)
Foreign Scan on blog_views  (cost=0.02..1.30 rows=128 width=8)
(actual time=0.005..0.168 rows=1000 loops=1)
Planning time: 0.113 ms
Execution time: 0.353 ms
(4 rows)
```

F.22.2.3. Deleting In-Memory Data

When a row is deleted from an in-memory table, data pages are not freed. To free the pages occupied by in-memory tables, you can:

- Delete the table using the `DROP FOREIGN TABLE` command.
- Truncate the table using the `TRUNCATE` command.

RESTART IDENTITY, CONTINUE IDENTITY, CASCADE, and RESTRICT options of the TRUNCATE command are not supported by in-memory tables.

F.22.2.4. Writing Data to In-Memory Tables on Hot Standby

In some cases, it can be useful to perform write operations on hot standby servers. For example, suppose you need to collect statistics on queries run on hot standby. Since in-memory tables are writable, you can use them for such purposes.

To set up in-memory tables for write queries on standby, create the required in-memory tables on the master server as explained in [Section F.22.2.1](#). Once the replication is complete, you can start writing data to these tables on hot standby.

Important

If the hot standby server is restarted, all the data stored in its in-memory tables gets truncated. You can continue writing data to the same in-memory tables, but all the previously stored data will be lost.

F.22.2.5. Getting Statistics on In-Memory Tables

To get statistics on in-memory pages available in your cluster, run the [in_memory_page_stats](#) function, which returns the number of all used and free in-memory pages, as well as the total number of pages allocated for in-memory tables. For example:

```
postgres=# SELECT * FROM in_memory.in_memory_page_stats();
 busy_pages | free_pages | all_pages
-----+-----+-----
          576 |          7616 |          8192
(1 row)
```

F.22.2.6. Fine-Tuning Memory Settings

F.22.2.6.1. Increasing Shared Memory Pool for In-Memory Tables

In-memory tables are stored in a separate shared memory segment. Its size is defined by the `in_memory.shared_pool_size` parameter. By default, this memory segment is limited to 8 MB.

If the data to be stored in in-memory tables exceeds the size of the allocated memory segment, the following error occurs:

```
ERROR: failed to get a new page: shared pool size is exceeded
```

To avoid such issues, you can increase the `in_memory.shared_pool_size` value, or limit the size of the stored data. Changing the shared pool size requires a server restart.

F.22.2.6.2. Managing the Undo Log

To enable multi-version concurrency control (MVCC), the `in_memory` module uses the *undo log* — a shared-memory ring buffer that stores the previous versions of data entries and pages. The size of the undo log is defined by the `in_memory.undo_size` parameter and is limited to 1 MB by default. If a buffer overflow occurs before a transaction is complete, the following error is returned:

```
ERROR: failed to add undo record: undo size is exceeded
```

To avoid this issue, you can increase the `in_memory.undo_size` value, or split the transactions into smaller ones.

If the required version of the entry or page has already been overwritten in the undo log when it is accessed for read, the following error occurs:

```
ERROR: snapshot is outdated
```

In this case, you can:

- Increase the `in_memory.undo_size` value. Changing this parameter requires a server restart.
- Ensure that the undo log is not truncated while the snapshot is in use. To achieve this, you can use the `READ COMMITTED` isolation level, or split a complex query into several smaller ones.

F.22.3. Reference

F.22.3.1. Configuration Variables

`in_memory.shared_pool_size (integer)`

Defines the size of the shared memory segment allocated for in-memory tables.

Default: 8MB

`in_memory.undo_size (integer)`

Defines the size of the undo log.

Default: 1MB

F.22.3.2. Functions

`in_memory.in_memory_page_stats()`

Displays statistics on pages of in-memory tables:

- `busy_pages` — in-memory pages containing any data.
- `free_pages` — empty in-memory pages. This number includes all the initially allocated pages to which no data has been written yet, as well as the pages from which all data has been deleted.
- `all_pages` — the total number of in-memory pages allocated on this server.

F.22.4. Authors

Postgres Professional, Moscow, Russia

F.23. intagg

The `intagg` module provides an integer aggregator and an enumerator. `intagg` is now obsolete, because there are built-in functions that provide a superset of its capabilities. However, the module is still provided as a compatibility wrapper around the built-in functions.

F.23.1. Functions

The aggregator is an aggregate function `int_array_aggregate(integer)` that produces an integer array containing exactly the integers it is fed. This is a wrapper around `array_agg`, which does the same thing for any array type.

The enumerator is a function `int_array_enum(integer[])` that returns `setof integer`. It is essentially the reverse operation of the aggregator: given an array of integers, expand it into a set of rows. This is a wrapper around `unnest`, which does the same thing for any array type.

F.23.2. Sample Uses

Many database systems have the notion of a one to many table. Such a table usually sits between two indexed tables, for example:

```
CREATE TABLE left (id INT PRIMARY KEY, ...);
CREATE TABLE right (id INT PRIMARY KEY, ...);
CREATE TABLE one_to_many(left INT REFERENCES left, right INT REFERENCES right);
```

It is typically used like this:

```
SELECT right.* from right JOIN one_to_many ON (right.id = one_to_many.right)
WHERE one_to_many.left = item;
```

This will return all the items in the right hand table for an entry in the left hand table. This is a very common construct in SQL.

Now, this methodology can be cumbersome with a very large number of entries in the `one_to_many` table. Often, a join like this would result in an index scan and a fetch for each right hand entry in the table for a particular left hand entry. If you have a very dynamic system, there is not much you can do. However, if you have some data which is fairly static, you can create a summary table with the aggregator.

```
CREATE TABLE summary AS
SELECT left, int_array_aggregate(right) AS right
FROM one_to_many
GROUP BY left;
```

This will create a table with one row per left item, and an array of right items. Now this is pretty useless without some way of using the array; that's why there is an array enumerator. You can do

```
SELECT left, int_array_enum(right) FROM summary WHERE left = item;
```

The above query using `int_array_enum` produces the same results as

```
SELECT left, right FROM one_to_many WHERE left = item;
```

The difference is that the query against the summary table has to get only one row from the table, whereas the direct query against `one_to_many` must index scan and fetch a row for each entry.

On one system, an `EXPLAIN` showed a query with a cost of 8488 was reduced to a cost of 329. The original query was a join involving the `one_to_many` table, which was replaced by:

```
SELECT right, count(right) FROM
( SELECT left, int_array_enum(right) AS right
  FROM summary JOIN (SELECT left FROM left_table WHERE left = item) AS lefts
    ON (summary.left = lefts.left)
) AS list
GROUP BY right
ORDER BY count DESC;
```

F.24. intarray

The `intarray` module provides a number of useful functions and operators for manipulating null-free arrays of integers. There is also support for indexed searches using some of the operators.

All of these operations will throw an error if a supplied array contains any `NULL` elements.

Many of these operations are only sensible for one-dimensional arrays. Although they will accept input arrays of more dimensions, the data is treated as though it were a linear array in storage order.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.24.1. intarray Functions and Operators

The functions provided by the `intarray` module are shown in [Table F.14](#), the operators in [Table F.15](#).

Table F.14. intarray Functions

Function	Description Example(s)
<code>icount (integer[]) → integer</code>	

Function	Description	Example(s)
	Returns the number of elements in the array.	<code>icount ('{1,2,3}'::integer[]) → 3</code>
<code>sort (integer[], dir text) → integer[]</code>	Sorts the array in either ascending or descending order. <i>dir</i> must be <code>asc</code> or <code>desc</code> .	<code>sort ('{1,3,2}'::integer[], 'desc') → {3,2,1}</code>
<code>sort (integer[]) → integer[]</code> <code>sort_asc (integer[]) → integer[]</code>	Sorts in ascending order.	<code>sort (array[11,77,44]) → {11,44,77}</code>
<code>sort_desc (integer[]) → integer[]</code>	Sorts in descending order.	<code>sort_desc (array[11,77,44]) → {77,44,11}</code>
<code>uniq (integer[]) → integer[]</code>	Removes adjacent duplicates. Often used with <code>sort</code> to remove all duplicates.	<code>uniq ('{1,2,2,3,1,1}'::integer[]) → {1,2,3,1}</code> <code>uniq (sort ('{1,2,3,2,1}'::integer[])) → {1,2,3}</code>
<code>idx (integer[], item integer) → integer</code>	Returns index of the first array element matching <i>item</i> , or 0 if no match.	<code>idx (array[11,22,33,22,11], 22) → 2</code>
<code>subarray (integer[], start integer, len integer) → integer[]</code>	Extracts the portion of the array starting at position <i>start</i> , with <i>len</i> elements.	<code>subarray ('{1,2,3,2,1}'::integer[], 2, 3) → {2,3,2}</code>
<code>subarray (integer[], start integer) → integer[]</code>	Extracts the portion of the array starting at position <i>start</i> .	<code>subarray ('{1,2,3,2,1}'::integer[], 2) → {2,3,2,1}</code>
<code>intset (integer) → integer[]</code>	Makes a single-element array.	<code>intset (42) → {42}</code>

Table F.15. intarray Operators

Operator	Description
<code>integer[] && integer[] → boolean</code>	Do arrays overlap (have at least one element in common)?
<code>integer[] @> integer[] → boolean</code>	Does left array contain right array?
<code>integer[] <@ integer[] → boolean</code>	Is left array contained in right array?
<code># integer[] → integer</code>	Returns the number of elements in the array.
<code>integer[] # integer → integer</code>	Returns index of the first array element matching the right argument, or 0 if no match. (Same as <code>idx</code> function.)

Operator	Description
<code>integer[] + integer → integer[]</code>	Adds element to end of array.
<code>integer[] + integer[] → integer[]</code>	Concatenates the arrays.
<code>integer[] - integer → integer[]</code>	Removes entries matching the right argument from the array.
<code>integer[] - integer[] → integer[]</code>	Removes elements of the right array from the left array.
<code>integer[] integer → integer[]</code>	Computes the union of the arguments.
<code>integer[] integer[] → integer[]</code>	Computes the union of the arguments.
<code>integer[] & integer[] → integer[]</code>	Computes the intersection of the arguments.
<code>integer[] @@ query_int → boolean</code>	Does array satisfy query? (see below)
<code>query_int ~~ integer[] → boolean</code>	Does array satisfy query? (commutator of @@)

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

The operators `&&`, `@>` and `<@` are equivalent to Postgres Pro's built-in operators of the same names, except that they work only on integer arrays that do not contain nulls, while the built-in operators work for any array type. This restriction makes them faster than the built-in operators in many cases.

The `@@` and `~~` operators test whether an array satisfies a *query*, which is expressed as a value of a specialized data type `query_int`. A *query* consists of integer values that are checked against the elements of the array, possibly combined using the operators `&` (AND), `|` (OR), and `!` (NOT). Parentheses can be used as needed. For example, the query `1&(2|3)` matches arrays that contain 1 and also contain either 2 or 3.

F.24.2. Index Support

`intarray` provides index support for the `&&`, `@>`, `<@`, and `@@` operators, as well as regular array equality.

Two parameterized GiST index operator classes are provided: `gist__int_ops` (used by default) is suitable for small- to medium-size data sets, while `gist__intbig_ops` uses a larger signature and is more suitable for indexing large data sets (i.e., columns containing a large number of distinct array values). The implementation uses an RD-tree data structure with built-in lossy compression.

`gist__int_ops` approximates an integer set as an array of integer ranges. Its optional integer parameter `numranges` determines the maximum number of ranges in one index key. The default value of `numranges` is 100. Valid values are between 1 and 253. Using larger arrays as GiST index keys leads to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

`gist__intbig_ops` approximates an integer set as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 16 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

There is also a non-default GIN operator class `gin__int_ops` supporting the same operators.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.24.3. Example

```
-- a message can be in one or more "sections"
CREATE TABLE message (mid INT PRIMARY KEY, sections INT[], ...);

-- create specialized index with signature length of 32 bytes
CREATE INDEX message_rdtree_idx ON message USING GIST (sections gist__intbig_ops
(siglen = 32));

-- select messages in section 1 OR 2 - OVERLAP operator
SELECT message.mid FROM message WHERE message.sections && '{1,2}';

-- select messages in sections 1 AND 2 - CONTAINS operator
SELECT message.mid FROM message WHERE message.sections @> '{1,2}';

-- the same, using QUERY operator
SELECT message.mid FROM message WHERE message.sections @@ '1&2'::query_int;
```

F.24.4. Authors

All work was done by Teodor Sigaev (<teodor@sigaev.ru>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Andrey Oktyabrski did a great work on adding new functions and operations.

F.25. isn

The `isn` module provides data types for the following international product numbering standards: EAN13, UPC, ISBN (books), ISMN (music), and ISSN (serials). Numbers are validated on input according to a hard-coded list of prefixes; this list of prefixes is also used to hyphenate numbers on output. Since new prefixes are assigned from time to time, the list of prefixes may be out of date. It is hoped that a future version of this module will obtain the prefix list from one or more tables that can be easily updated by users as needed; however, at present, the list can only be updated by modifying the source code and recompiling. Alternatively, prefix validation and hyphenation support may be dropped from a future version of this module.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.25.1. Data Types

[Table F.16](#) shows the data types provided by the `isn` module.

Table F.16. isn Data Types

Data Type	Description
EAN13	European Article Numbers, always displayed in the EAN13 display format
ISBN13	International Standard Book Numbers to be displayed in the new EAN13 display format
ISMN13	International Standard Music Numbers to be displayed in the new EAN13 display format
ISSN13	International Standard Serial Numbers to be displayed in the new EAN13 display format

Data Type	Description
ISBN	International Standard Book Numbers to be displayed in the old short display format
ISMN	International Standard Music Numbers to be displayed in the old short display format
ISSN	International Standard Serial Numbers to be displayed in the old short display format
UPC	Universal Product Codes

Some notes:

1. ISBN13, ISMN13, ISSN13 numbers are all EAN13 numbers.
2. EAN13 numbers aren't always ISBN13, ISMN13 or ISSN13 (some are).
3. Some ISBN13 numbers can be displayed as ISBN.
4. Some ISMN13 numbers can be displayed as ISMN.
5. Some ISSN13 numbers can be displayed as ISSN.
6. UPC numbers are a subset of the EAN13 numbers (they are basically EAN13 without the first 0 digit).
7. All UPC, ISBN, ISMN and ISSN numbers can be represented as EAN13 numbers.

Internally, all these types use the same representation (a 64-bit integer), and all are interchangeable. Multiple types are provided to control display formatting and to permit tighter validity checking of input that is supposed to denote one particular type of number.

The `ISBN`, `ISMN`, and `ISSN` types will display the short version of the number (ISxN 10) whenever it's possible, and will show ISxN 13 format for numbers that do not fit in the short version. The `EAN13`, `ISBN13`, `ISMN13` and `ISSN13` types will always display the long version of the ISxN (EAN13).

F.25.2. Casts

The `isn` module provides the following pairs of type casts:

- `ISBN13 <=> EAN13`
- `ISMN13 <=> EAN13`
- `ISSN13 <=> EAN13`
- `ISBN <=> EAN13`
- `ISMN <=> EAN13`
- `ISSN <=> EAN13`
- `UPC <=> EAN13`
- `ISBN <=> ISBN13`
- `ISMN <=> ISMN13`
- `ISSN <=> ISSN13`

When casting from `EAN13` to another type, there is a run-time check that the value is within the domain of the other type, and an error is thrown if not. The other casts are simply relabelings that will always succeed.

F.25.3. Functions and Operators

The `isn` module provides the standard comparison operators, plus B-tree and hash indexing support for all these data types. In addition there are several specialized functions; shown in [Table F.17](#). In this table, `isn` means any one of the module's data types.

Table F.17. isn Functions

Function	Description
<code>isn_weak (boolean) → boolean</code>	Sets the weak input mode, and returns new setting.
<code>isn_weak () → boolean</code>	Returns the current status of the weak mode.
<code>make_valid (isn) → isn</code>	Validates an invalid number (clears the invalid flag).
<code>is_valid (isn) → boolean</code>	Checks for the presence of the invalid flag.

Weak mode is used to be able to insert invalid data into a table. Invalid means the check digit is wrong, not that there are missing numbers.

Why would you want to use the weak mode? Well, it could be that you have a huge collection of ISBN numbers, and that there are so many of them that for weird reasons some have the wrong check digit (perhaps the numbers were scanned from a printed list and the OCR got the numbers wrong, perhaps the numbers were manually captured... who knows). Anyway, the point is you might want to clean the mess up, but you still want to be able to have all the numbers in your database and maybe use an external tool to locate the invalid numbers in the database so you can verify the information and validate it more easily; so for example you'd want to select all the invalid numbers in the table.

When you insert invalid numbers in a table using the weak mode, the number will be inserted with the corrected check digit, but it will be displayed with an exclamation mark (!) at the end, for example 0-11-000322-5!. This invalid marker can be checked with the `is_valid` function and cleared with the `make_valid` function.

You can also force the insertion of invalid numbers even when not in the weak mode, by appending the `!` character at the end of the number.

Another special feature is that during input, you can write `?` in place of the check digit, and the correct check digit will be inserted automatically.

F.25.4. Examples

```
--Using the types directly:
SELECT isbn('978-0-393-04002-9');
SELECT isbn13('0901690546');
SELECT issn('1436-4522');

--Casting types:
-- note that you can only cast from ean13 to another type when the
-- number would be valid in the realm of the target type;
-- thus, the following will NOT work: select isbn(ean13('0220356483481'));
-- but these will:
SELECT upc(ean13('0220356483481'));
SELECT ean13(upc('220356483481'));

--Create a table with a single column to hold ISBN numbers:
CREATE TABLE test (id isbn);
INSERT INTO test VALUES('9780393040029');

--Automatically calculate check digits (observe the '?'):
INSERT INTO test VALUES('220500896?');
INSERT INTO test VALUES('978055215372?');
```

```
SELECT issn('3251231?');
SELECT ismn('979047213542?');

--Using the weak mode:
SELECT isn_weak(true);
INSERT INTO test VALUES('978-0-11-000533-4');
INSERT INTO test VALUES('9780141219307');
INSERT INTO test VALUES('2-205-00876-X');
SELECT isn_weak(false);

SELECT id FROM test WHERE NOT is_valid(id);
UPDATE test SET id = make_valid(id) WHERE id = '2-205-00876-X!';

SELECT * FROM test;

SELECT isbn13(id) FROM test;
```

F.25.5. Bibliography

The information to implement this module was collected from several sites, including:

- <https://www.isbn-international.org/>
- <https://www.issn.org/>
- <https://www.ismn-international.org/>
- <https://www.wikipedia.org/>

The prefixes used for hyphenation were also compiled from:

- <https://www.gs1.org/standards/id-keys>
- https://en.wikipedia.org/wiki/List_of_ISBN_identifier_groups
- <https://www.isbn-international.org/content/isbn-users-manual>
- https://en.wikipedia.org/wiki/International_Standard_Music_Number
- <https://www.ismn-international.org/ranges.html>

Care was taken during the creation of the algorithms and they were meticulously verified against the suggested algorithms in the official ISBN, ISMN, ISSN User Manuals.

F.25.6. Author

Germán Méndez Bravo (Kronuz), 2004-2006

This module was inspired by Garrett A. Wollman's `isbn_issn` code.

F.26. jquery

jQuery is a language to query `jsonb` data type. Its primary goal is to provide an additional functionality for `jsonb`, such as a simple and effective way for search in nested objects and arrays, as well as additional comparison operators with index support.

jQuery is implemented by means of a `jquery` data type (similar to `tsquery`) and the `@@` match operator for `jsonb`.

F.26.1. Installation

Postgres Pro Enterprise distribution includes `jquery` as a contrib module. Once you complete Postgres Pro Enterprise installation, create the `jquery` extension, as follows:

```
CREATE EXTENSION jquery;
```

F.26.2. JSON query language

JsQuery extension contains `jsquery` datatype which represents whole JSON query as a single value (like `tsquery` does for fulltext search). The query is an expression on JSON-document values.

Simple expression is specified as *path binary_operator value* or *path unary_operator*. See the following examples.

- `x = "abc"` - value of key "x" is equal to "abc";
- `$ @> [4, 5, "zzz"]` - the JSON document is an array containing values 4, 5 and "zzz";
- `"abc xyz" >= 10` - value of key "abc xyz" is greater than or equal to 10;
- `volume IS NUMERIC` - type of key "volume" is numeric.
- `$ = true` - the whole JSON document is just a true.
- `similar_ids.@# > 5` - `similar_ids` is an array or object of length greater than 5;
- `similar_product_ids.# = "0684824396"` - array `similar_product_ids` contains string "0684824396".
- `*.color = "red"` - there is object somewhere which key "color" has value "red".
- `foo = *` - key "foo" exists in object.

Path selects set of JSON values to be checked using given operators. In the simplest case, path is just a key name. In general, path is key names and placeholders combined by dot signs. Path can use the following placeholders:

- `#` - any index of array;
- `#N` - Nth index of array;
- `%` - any key of object;
- `*` - any sequence of array indexes and object keys;
- `@#` - length of array or object, could be only used as last component of path;
- `$` - the whole JSON document as single value, could be only the whole path.

Expression is true when operator is true against at least one value selected by path.

Key names could be given either with or without double quotes. Key names without double quotes shouldn't contain spaces, start with number, or concur with `jsquery` keyword.

The supported binary operators are:

- Equality operator: `=`;
- Numeric comparison operators: `>`, `>=`, `<`, `<=`;
- Search in the list of scalar values using `IN` operator;
- Array comparison operators: `&&` (overlap), `@>` (contains), `<@` (contained in).
- Filtering operator: `~~`. Taking `jsonb` data as the left operand and a `jsquery` expression as the right operand, this operator checks that `jsonb` data contains any entries that satisfy the condition provided in a `jsquery` expression and returns an array of such entries, if any.

The supported unary operators are:

- Check for existence operator: `= *`;
- Check for type operators: `IS ARRAY`, `IS NUMERIC`, `IS OBJECT`, `IS STRING` and `IS BOOLEAN`.

Expressions could be complex. Complex expression is a set of expressions combined by logical operators (`AND`, `OR`, `NOT`) and grouped using parentheses.

Examples of complex expressions are given below.

- `a = 1 AND (b = 2 OR c = 3) AND NOT d = 1`
- `x.% = true OR x.# = true`

Prefix expressions are expressions given in the form `path (subexpression)`. In this case path selects JSON values to be checked using given subexpression. Check results are aggregated in the same way as in simple expressions.

- `#(a = 1 AND b = 2)` - an array contains an element where the `a` key is 1 and the `b` key is 2
- `%($ >= 10 AND $ <= 20)` - an object contains a key with a value between 10 and 20

Path also could contain the following special placeholders with "every" semantics:

- `#:` - every index of array;
- `%:` - every key of object;
- `*:` - every sequence of array indexes and object keys.

Consider the following example.

```
%.#:($ >= 0 AND $ <= 1)
```

This example could be read as follows: there is at least one key for which the value is an array of numerics between 0 and 1.

We can rewrite this example in the following form with extra parentheses.

```
%(#:($ >= 0 AND $ <= 1))
```

The first placeholder `%` checks that expression in parentheses is true for at least one value in object. The second placeholder `#:` checks that the value is an array and all its elements satisfy expressions in parentheses.

We can rewrite this example without `#:` placeholder as follows.

```
%(NOT #(NOT ($ >= 0 AND $ <= 1)) AND $ IS ARRAY)
```

In this example we transform assertion that every element of array satisfies some condition to assertion that there is no one element which doesn't satisfy the same condition.

Some examples of using paths are given below.

- `numbers.#: IS NUMERIC` - every element of "numbers" array is numeric.
- `*:($ IS OBJECT OR $ IS BOOLEAN)` - JSON is a structure of nested objects with booleans as leaf values.
- `#.%.#:($ >= 0 AND $ <= 1)` - each element of array is object containing only numeric values between 0 and 1.
- `documents.#:.% = *` - "documents" is an array of objects containing at least one key.
- `%.#:($ IS STRING)` - JSON object contains at least one array of strings.
- `#.% = true` - at least one array element is an object that contains at least one "true" value.

Usage of path operators and parentheses needs some explanation. When same path operators are used multiple times they may refer to different values while you can refer to the same value multiple times by using parentheses and `$` operator. See the following examples.

- `# < 10 AND # > 20` - there is an element less than 10 and another element greater than 20.
- `#$ < 10 AND $ > 20` - there is an element that is both less than 10 and greater than 20 (impossible).
- `#$ >= 10 AND $ <= 20` - there is an element between 10 and 20.
- `# >= 10 AND # <= 20` - there is an element greater than or equal to 10 and another element less than or equal to 20. The query can be satisfied by an array with no elements between 10 and 20, for instance `[0,30]`.

Same rules apply when you search inside objects and branchy structures.

Type checking operators and "every" placeholders are useful for document schema validation. JQuery matching operator `@` is immutable and can be used in CHECK constraint. See the following example.

```
CREATE TABLE js (  
    id serial,  
    data jsonb,
```

```
CHECK (data @@ '
    name IS STRING AND
    similar_ids.#: IS NUMERIC AND
    points.#:(x IS NUMERIC AND y IS NUMERIC) '::jsquery));
```

In this example check constraint validates that in "data" jsonb column: value of "name" key is string, value of "similar_ids" key is array of numerics, value of "points" key is array of objects which contain numeric values in "x" and "y" keys.

See our [pgconf.eu presentation](https://www.pgconf.eu/presentation) for more examples.

F.26.3. GIN indexes

JsQuery extension contains two operator classes (opclasses) for GIN which provide different kinds of query optimization.

- `jsonb_path_value_ops`
- `jsonb_value_path_ops`

In each of two GIN opclasses jsonb documents are decomposed into entries. Each entry is associated with a particular value and its path. Difference between opclasses is in the entry representation, comparison, and usage for search optimization.

For example, jsonb document `{"a": [{"b": "xyz", "c": true}, 10], "d": {"e": [7, false]}}` would be decomposed into the following entries:

- `"a".#."b"."xyz"`
- `"a".#."c".true`
- `"a".#.10`
- `"d"."e".#.7`
- `"d"."e".#.false`

Since JsQuery doesn't support search in a particular array index, we consider all array elements to be equivalent. Thus, each array element is marked with the same # sign in the path.

Major problem in the entries representation is its size. In the given example key "a" is presented three times. In the large branchy documents with long keys size of naive entries representation becomes unreasonable. Both opclasses address this issue but in a slightly different way.

F.26.3.1. `jsonb_path_value_ops`

`jsonb_path_value_ops` represents entry as pair of path hash and value. The following pseudocode illustrates it.

```
(hash(path_item_1.path_item_2. ... .path_item_n); value)
```

In comparison of entries path hash is the higher part of entry and value is its lower part. This determines the features of this opclass. Since path is hashed and it is higher part of entry we need to know the full path to the value in order to use it for search. However, once path is specified we can use both exact and range searches very efficiently.

F.26.3.2. `jsonb_value_path_ops`

`jsonb_value_path_ops` represents entry as pair of value and bloom filter of path.

```
(value; bloom(path_item_1) | bloom(path_item_2) | ... | bloom(path_item_n))
```

In comparison of entries value is the higher part of entry and bloom filter of path is its lower part. This determines the features of this opclass. Since value is the higher part of entry we can perform only exact value search efficiently. Range value search is possible as well but we would have to filter all the different paths where matching values occur. Bloom filter over path items allows index usage for conditions containing % and * in their paths.

F.26.3.3. Query optimization

JsQuery opclasses perform complex query optimization. Thus it's valuable for developer or administrator to see the result of such optimization. Unfortunately, opclasses aren't allowed to do any custom output to the EXPLAIN. That's why JsQuery provides the following functions which allows to see how particular opclass optimizes given query.

- `gin_debug_query_path_value(jsquery)` - for `jsonb_path_value_ops`
- `gin_debug_query_value_path(jsquery)` - for `jsonb_value_path_ops`

Result of these functions is a textual representation of query tree which leaves are GIN search entries. The following examples show different results of query optimization by different opclasses.

```
# SELECT gin_debug_query_path_value('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_path_value
-----
x = 1 , entry 0          +

# SELECT gin_debug_query_value_path('x = 1 AND (*.y = 1 OR y = 2)');
gin_debug_query_value_path
-----
AND                      +
  x = 1 , entry 0        +
  OR                      +
    *.y = 1 , entry 1    +
    y = 2 , entry 2      +
```

Unfortunately, `jsonb` has no statistics yet. That's why JsQuery optimizer has to do imperative decision while selecting conditions to be evaluated using index. This decision is made by assumption that some condition types are less selective than others. Optimizer divides conditions into the following selectivity class (listed by descending of selectivity).

1. Equality (`x = c`)
2. Range (`c1 < x < c2`)
3. Inequality (`x > c`)
4. Is (`x is type`)
5. Any (`x = *`)

Optimizer evades index evaluation of less selective conditions when possible. For example, in the `x = 1 AND y > 0` query `x = 1` is assumed to be more selective than `y > 0`. That's why index isn't used for evaluation of `y > 0`.

```
# SELECT gin_debug_query_path_value('x = 1 AND y > 0');
gin_debug_query_path_value
-----
x = 1 , entry 0          +
```

With lack of statistics decisions made by optimizer can be inaccurate. That's why JsQuery supports hints. Comments `/*-- index */` and `/*-- noindex */` placed in the conditions force optimizer to use and not to use index correspondingly.

```
SELECT gin_debug_query_path_value('x = 1 AND y /*-- index */ > 0');
gin_debug_query_path_value
-----
AND                      +
  x = 1 , entry 0        +
  y > 0 , entry 1        +

SELECT gin_debug_query_path_value('x /*-- noindex */ = 1 AND y > 0');
gin_debug_query_path_value
-----
```

`y > 0 , entry 0 +`

F.26.5. Credits

Development is sponsored by Wargaming.net.

F.27. lo

The `lo` module provides support for managing Large Objects (also called LOs or BLOBs). This includes a data type `lo` and a trigger `lo_manage`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.27.1. Rationale

One of the problems with the JDBC driver (and this affects the ODBC driver also), is that the specification assumes that references to BLOBs (Binary Large Objects) are stored within a table, and if that entry is changed, the associated BLOB is deleted from the database.

As Postgres Pro stands, this doesn't occur. Large objects are treated as objects in their own right; a table entry can reference a large object by OID, but there can be multiple table entries referencing the same large object OID, so the system doesn't delete the large object just because you change or remove one such entry.

Now this is fine for Postgres Pro-specific applications, but standard code using JDBC or ODBC won't delete the objects, resulting in orphan objects — objects that are not referenced by anything, and simply occupy disk space.

The `lo` module allows fixing this by attaching a trigger to tables that contain LO reference columns. The trigger essentially just does a `lo_unlink` whenever you delete or modify a value referencing a large object. When you use this trigger, you are assuming that there is only one database reference to any large object that is referenced in a trigger-controlled column!

The module also provides a data type `lo`, which is really just a domain of the `oid` type. This is useful for differentiating database columns that hold large object references from those that are OIDs of other things. You don't have to use the `lo` type to use the trigger, but it may be convenient to use it to keep track of which columns in your database represent large objects that you are managing with the trigger. It is also rumored that the ODBC driver gets confused if you don't use `lo` for BLOB columns.

F.27.2. How to Use It

Here's a simple example of usage:

```
CREATE TABLE image (title text, raster lo);
```

```
CREATE TRIGGER t_raster BEFORE UPDATE OR DELETE ON image
FOR EACH ROW EXECUTE FUNCTION lo_manage(raster);
```

For each column that will contain unique references to large objects, create a `BEFORE UPDATE OR DELETE` trigger, and give the column name as the sole trigger argument. You can also restrict the trigger to only execute on updates to the column by using `BEFORE UPDATE OF column_name`. If you need multiple `lo` columns in the same table, create a separate trigger for each one, remembering to give a different name to each trigger on the same table.

F.27.3. Limitations

- Dropping a table will still orphan any objects it contains, as the trigger is not executed. You can avoid this by preceding the `DROP TABLE` with `DELETE FROM table`.

`TRUNCATE` has the same hazard.

If you already have, or suspect you have, orphaned large objects, see the [vacuumlo](#) module to help you clean them up. It's a good idea to run `vacuumlo` occasionally as a back-stop to the `lo_manage` trigger.

- Some frontends may create their own tables, and will not create the associated trigger(s). Also, users may not remember (or know) to create the triggers.

Peter Mount <peter@retexp.org.uk>

F.28. ltree

This module implements a data type `ltree` for representing labels of data stored in a hierarchical tree-like structure. Extensive facilities for searching through label trees are provided.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.28.1. Definitions

A *label* is a sequence of alphanumeric characters and underscores (for example, in C locale the characters `A-Za-z0-9_` are allowed). Labels must be less than 256 characters long.

Examples: `42`, `Personal_Services`

A *label path* is a sequence of zero or more labels separated by dots, for example `L1.L2.L3`, representing a path from the root of a hierarchical tree to a particular node. The length of a label path cannot exceed 65535 labels.

Example: `Top.Countries.Europe.Russia`

The `ltree` module provides several data types:

- `ltree` stores a label path.
- `lquery` represents a regular-expression-like pattern for matching `ltree` values. A simple word matches that label within a path. A star symbol (`*`) matches zero or more labels. These can be joined with dots to form a pattern that must match the whole label path. For example:

<code>foo</code>	Match the exact label path <code>foo</code>
<code>*.foo.*</code>	Match any label path containing the label <code>foo</code>
<code>*.foo</code>	Match any label path whose last label is <code>foo</code>

Both star symbols and simple words can be quantified to restrict how many labels they can match:

<code>{n}</code>	Match exactly <code>n</code> labels
<code>{n,}</code>	Match at least <code>n</code> labels
<code>{n,m}</code>	Match at least <code>n</code> but not more than <code>m</code> labels
<code>{,m}</code>	Match at most <code>m</code> labels – same as <code>{0,m}</code>
<code>foo{n,m}</code>	Match at least <code>n</code> but not more than <code>m</code> occurrences of <code>foo</code>
<code>foo{,}</code>	Match any number of occurrences of <code>foo</code> , including zero

In the absence of any explicit quantifier, the default for a star symbol is to match any number of labels (that is, `{,}`) while the default for a non-star item is to match exactly once (that is, `{1}`).

There are several modifiers that can be put at the end of a non-star `lquery` item to make it match more than just the exact match:

```
@      Match case-insensitively, for example a@ matches A
*      Match any label with this prefix, for example foo* matches foobar
%      Match initial underscore-separated words
```

The behavior of `%` is a bit complicated. It tries to match words rather than the entire label. For example `foo_bar%` matches `foo_bar_baz` but not `foo_barbaz`. If combined with `*`, prefix matching applies to each word separately, for example `foo_bar%*` matches `foo1_bar2_baz` but not `foo1_br2_baz`.

Also, you can write several possibly-modified non-star items separated with `|` (OR) to match any of those items, and you can put `!` (NOT) at the start of a non-star group to match any label that doesn't match any of the alternatives. A quantifier, if any, goes at the end of the group; it means some number of matches for the group as a whole (that is, some number of labels matching or not matching any of the alternatives).

Here's an annotated example of `lquery`:

```
Top.*{0,2}.sport*@.!football|tennis{1,}.Russ*|Spain
a.  b.      c.      d.                  e.
```

This query will match any label path that:

- a. begins with the label `Top`
 - b. and next has zero to two labels before
 - c. a label beginning with the case-insensitive prefix `sport`
 - d. then has one or more labels, none of which match `football` nor `tennis`
 - e. and then ends with a label beginning with `Russ` or exactly matching `Spain`.
- `ltxquery` represents a full-text-search-like pattern for matching `ltree` values. An `ltxquery` value contains words, possibly with the modifiers `@`, `*`, `%` at the end; the modifiers have the same meanings as in `lquery`. Words can be combined with `&` (AND), `|` (OR), `!` (NOT), and parentheses. The key difference from `lquery` is that `ltxquery` matches words without regard to their position in the label path.

Here's an example `ltxquery`:

```
Europe & Russia*@ & !Transportation
```

This will match paths that contain the label `Europe` and any label beginning with `Russia` (case-insensitive), but not paths containing the label `Transportation`. The location of these words within the path is not important. Also, when `%` is used, the word can be matched to any underscore-separated word within a label, regardless of position.

Note: `ltxquery` allows whitespace between symbols, but `ltree` and `lquery` do not.

F.28.2. Operators and Functions

Type `ltree` has the usual comparison operators `=`, `<>`, `<`, `>`, `<=`, `>=`. Comparison sorts in the order of a tree traversal, with the children of a node sorted by label text. In addition, the specialized operators shown in [Table F.18](#) are available.

Table F.18. `ltree` Operators

Operator	Description
<code>ltree @> ltree</code>	<code>→ boolean</code>

Operator	Description
	Is left argument an ancestor of right (or equal)?
<code>ltree <@ ltree → boolean</code> <code>ltree <@ ltree → boolean</code>	Is left argument a descendant of right (or equal)?
<code>ltree ~ lquery → boolean</code> <code>lquery ~ ltree → boolean</code>	Does ltree match lquery?
<code>ltree ? lquery[] → boolean</code> <code>lquery[] ? ltree → boolean</code>	Does ltree match any lquery in array?
<code>ltree @ ltxtquery → boolean</code> <code>ltxtquery @ ltree → boolean</code>	Does ltree match ltxtquery?
<code>ltree ltree → ltree</code>	Concatenates ltree paths.
<code>ltree text → ltree</code> <code>text ltree → ltree</code>	Converts text to ltree and concatenates.
<code>ltree[] @> ltree → boolean</code> <code>ltree <@ ltree[] → boolean</code>	Does array contain an ancestor of ltree?
<code>ltree[] <@ ltree → boolean</code> <code>ltree @> ltree[] → boolean</code>	Does array contain a descendant of ltree?
<code>ltree[] ~ lquery → boolean</code> <code>lquery ~ ltree[] → boolean</code>	Does array contain any path matching lquery?
<code>ltree[] ? lquery[] → boolean</code> <code>lquery[] ? ltree[] → boolean</code>	Does ltree array contain any path matching any lquery?
<code>ltree[] @ ltxtquery → boolean</code> <code>ltxtquery @ ltree[] → boolean</code>	Does array contain any path matching ltxtquery?
<code>ltree[] ?@> ltree → ltree</code>	Returns first array entry that is an ancestor of ltree, or NULL if none.
<code>ltree[] ?<@ ltree → ltree</code>	Returns first array entry that is a descendant of ltree, or NULL if none.
<code>ltree[] ?~ lquery → ltree</code>	Returns first array entry that matches lquery, or NULL if none.
<code>ltree[] ?@ ltxtquery → ltree</code>	Returns first array entry that matches ltxtquery, or NULL if none.

The operators `<@`, `@>`, `@` and `~` have analogues `^<@`, `^@>`, `^@`, `^~`, which are the same except they do not use indexes. These are useful only for testing purposes.

The available functions are shown in [Table F.19](#).

Table F.19. ltree Functions

Function	Description	Example(s)
<code>subltree (ltree, start integer, end integer) → ltree</code>	Returns subpath of <code>ltree</code> from position <code>start</code> to position <code>end-1</code> (counting from 0).	<code>subltree('Top.Child1.Child2', 1, 2) → Child1</code>
<code>subpath (ltree, offset integer, len integer) → ltree</code>	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , with length <code>len</code> . If <code>offset</code> is negative, subpath starts that far from the end of the path. If <code>len</code> is negative, leaves that many labels off the end of the path.	<code>subpath('Top.Child1.Child2', 0, 2) → Top.Child1</code>
<code>subpath (ltree, offset integer) → ltree</code>	Returns subpath of <code>ltree</code> starting at position <code>offset</code> , extending to end of path. If <code>offset</code> is negative, subpath starts that far from the end of the path.	<code>subpath('Top.Child1.Child2', 1) → Child1.Child2</code>
<code>nlevel (ltree) → integer</code>	Returns number of labels in path.	<code>nlevel('Top.Child1.Child2') → 3</code>
<code>index (a ltree, b ltree) → integer</code>	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6') → 6</code>
<code>index (a ltree, b ltree, offset integer) → integer</code>	Returns position of first occurrence of <code>b</code> in <code>a</code> , or -1 if not found. The search starts at position <code>offset</code> ; negative <code>offset</code> means start <code>-offset</code> labels from the end of the path.	<code>index('0.1.2.3.5.4.5.6.8.5.6.8', '5.6', -4) → 9</code>
<code>text2ltree (text) → ltree</code>	Casts <code>text</code> to <code>ltree</code> .	
<code>ltree2text (ltree) → text</code>	Casts <code>ltree</code> to <code>text</code> .	
<code>lca (ltree [, ltree [, ...]]) → ltree</code>	Computes longest common ancestor of paths (up to 8 arguments are supported).	<code>lca('1.2.3', '1.2.3.4.5.6') → 1.2</code>
<code>lca (ltree[]) → ltree</code>	Computes longest common ancestor of paths in array.	<code>lca(array['1.2.3'::ltree, '1.2.3.4']) → 1.2</code>

F.28.3. Indexes

`ltree` supports several types of indexes that can speed up the indicated operators:

- B-tree index over `ltree`: `<`, `<=`, `=`, `>=`, `>`
- GiST index over `ltree` (`gist_ltree_ops` opclass): `<`, `<=`, `=`, `>=`, `>`, `@>`, `<@`, `@`, `~`, `?`

`gist_ltree_ops` GiST opclass approximates a set of path labels as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default signature length is 8 bytes. The length must be a positive multiple of `int` alignment (4 bytes on most machines) up to

2024. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with the default signature length of 8 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (path gist_ltree_ops(siglen=100));
```

- **GiST index over ltree[] (gist__ltree_ops opclass):** ltree[] <@ ltree, ltree @> ltree[], @, ~, ?

gist__ltree_ops GiST opclass works similarly to gist_ltree_ops and also takes signature length as a parameter. The default value of siglen in gist__ltree_ops is 28 bytes.

Example of creating such an index with the default signature length of 28 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path);
```

Example of creating such an index with a signature length of 100 bytes:

```
CREATE INDEX path_gist_idx ON test USING GIST (array_path
gist__ltree_ops(siglen=100));
```

Note: This index type is lossy.

F.28.4. Example

This example uses the following data (also available in file contrib/ltree/ltreetest.sql in the source distribution):

```
CREATE TABLE test (path ltree);
INSERT INTO test VALUES ('Top');
INSERT INTO test VALUES ('Top.Science');
INSERT INTO test VALUES ('Top.Science.Astronomy');
INSERT INTO test VALUES ('Top.Science.Astronomy.Astrophysics');
INSERT INTO test VALUES ('Top.Science.Astronomy.Cosmology');
INSERT INTO test VALUES ('Top.Hobbies');
INSERT INTO test VALUES ('Top.Hobbies.Amateurs_Astronomy');
INSERT INTO test VALUES ('Top.Collections');
INSERT INTO test VALUES ('Top.Collections.Pictures');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Stars');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Galaxies');
INSERT INTO test VALUES ('Top.Collections.Pictures.Astronomy.Astronauts');
CREATE INDEX path_gist_idx ON test USING GIST (path);
CREATE INDEX path_idx ON test USING BTREE (path);
```

Now, we have a table test populated with data describing the hierarchy shown below:

```

      Top
     /  |  \
  Science Hobbies Collections
    /      |      \
Astrophysics Amateurs_Astronomy Pictures
  /  \                |
Astrophysics Cosmology      Astronomy
                        /  |  \
                        Galaxies Stars Astronauts
```

We can do inheritance:

```
ltreetest=> SELECT path FROM test WHERE path <@ 'Top.Science';
           path
```

```
-----
Top.Science
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(4 rows)
```

Here are some examples of path matching:

```
ltreetest=> SELECT path FROM test WHERE path ~ '*.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Collections.Pictures.Astronomy
Top.Collections.Pictures.Astronomy.Stars
Top.Collections.Pictures.Astronomy.Galaxies
Top.Collections.Pictures.Astronomy.Astronauts
(7 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path ~ '.*!pictures@.Astronomy.*';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Here are some examples of full text search:

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro*% & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
Top.Hobbies.Amateurs_Astronomy
(4 rows)
```

```
ltreetest=> SELECT path FROM test WHERE path @ 'Astro* & !pictures@';
           path
```

```
-----
Top.Science.Astronomy
Top.Science.Astronomy.Astrophysics
Top.Science.Astronomy.Cosmology
(3 rows)
```

Path construction using functions:

```
ltreetest=> SELECT subpath(path,0,2)||'Space'||subpath(path,2) FROM test WHERE path <@
           'Top.Science.Astronomy';
           ?column?
```

```
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

We could simplify this by creating a SQL function that inserts a label at a specified position in a path:

```
CREATE FUNCTION ins_label(ltree, int, text) RETURNS ltree
AS 'select subpath($1,0,$2) || $3 || subpath($1,$2);'
LANGUAGE SQL IMMUTABLE;

ltreetest=> SELECT ins_label(path,2,'Space') FROM test WHERE path <@
'Top.Science.Astronomy';
           ins_label
-----
Top.Science.Space.Astronomy
Top.Science.Space.Astronomy.Astrophysics
Top.Science.Space.Astronomy.Cosmology
(3 rows)
```

F.28.5. Transforms

Additional extensions are available that implement transforms for the `ltree` type for PL/Python. The extensions are called `ltree_plpythonu`, `ltree_plpython2u`, and `ltree_plpython3u` (see [Section 47.1](#) for the PL/Python naming convention). If you install these transforms and specify them when creating a function, `ltree` values are mapped to Python lists. (The reverse is currently not supported, however.)

Caution

It is strongly recommended that the transform extensions be installed in the same schema as `ltree`. Otherwise there are installation-time security hazards if a transform extension's schema contains objects defined by a hostile user.

F.28.6. Authors

All work was done by Teodor Sigaev (<teodor@stack.net>) and Oleg Bartunov (<oleg@sai.msu.su>). See <http://www.sai.msu.su/~megera/postgres/gist/> for additional information. Authors would like to thank Eugeny Rodichev for helpful discussions. Comments and bug reports are welcome.

F.29. mchar

The `mchar` module provides additional data types for compatibility with Microsoft SQL Server (MS SQL).

F.29.1. Overview

This module has been designed to improve 1C Enterprise support, most popular Russian CRM and ERP system.

It implements types `MCHAR` and `MVARCHAR`, which are bug-to-bug compatible with MS SQL `CHAR` and `VARCHAR` respectively. Additionally, these types use the ICU library for comparison and case conversion, so their behavior is identical across different operating systems.

Postgres Pro also includes [citext](#) extension which provides types similar to `MCHAR`. But this extension doesn't emulate MS-SQL behavior concerning end-of-value whitespace.

Differences from Postgres Pro standard `CHAR` and `VARCHAR` are:

- Case insensitive comparison
- Handling of the whitespace at the end of string
- These types are always stored as two-byte unicode value regardless of database encoding.

F.29.2. Additional types

- `mchar` — analog of the MS SQL char type

- `mvarchar` — analog of the MS SQL `varchar` type

F.29.3. MCHAR and MVARCHAR features

- Defines `length(str)` function
- Defines `substr(str, pos[, length])` function
- Defines `||` operator, which would be applied to concatenate any (`mchar` and `mvarchar`) arguments
- Defines set of operators: `<`, `<=`, `=`, `>=`, `>` for case-insensitive comparison (ICU)
- Defines set of operators: `&<`, `&<=`, `&=`, `&>=`, `&>` to case-sensitive comparison (ICU)
- Implicit cast between `mchar` and `mvarchar` types
- B-tree and Hash-index support
- The `LIKE [ESCAPE]` operator support
- The `SIMILAR TO [ESCAPE]` operator support
- The `~` operator (POSIX regexp) support
- Index support for the *LIKE* operator

F.29.4. Authors

Oleg Bartunov <oleg@sai.msu.ru>
Teodor Sigaev <teodor@sigaev.ru>

F.30. multimaster

`multimaster` is a Postgres Pro Enterprise extension with a set of patches that turns Postgres Pro Enterprise into a synchronous shared-nothing cluster to provide Online Transaction Processing (OLTP) scalability for read transactions and high availability with automatic disaster recovery.

As compared to a standard PostgreSQL master-standby cluster, a cluster configured with the `multimaster` extension offers the following benefits:

- Fault tolerance and automatic node recovery
- Synchronous logical replication and DDL replication
- Read scalability
- Working with temporary tables on each cluster node
- Upgrading minor releases of Postgres Pro Enterprise seamlessly for multimaster cluster clients.

Important

Before deploying `multimaster` on production systems, make sure to take its replication restrictions into account. For details, see [Section F.30.1](#).

The `multimaster` extension replicates your database to all nodes of the cluster and allows write transactions on each node. Write transactions are synchronously replicated to all nodes, which increases commit latency. Read-only transactions and queries are executed locally, without any measurable overhead.

To ensure high availability and fault tolerance of the cluster, `multimaster` determines each transaction outcome through Paxos consensus algorithm, uses custom recovery protocol and heartbeats for failure

discovery. A multi-master cluster of N nodes can continue working while the majority of the nodes are alive and reachable by other nodes. To be configured with `multimaster`, the cluster must include at least three nodes. Since the data on all cluster nodes is the same, you do not typically need more than five cluster nodes. There is also a special 2+1 (referee) mode in which 2 nodes hold data and an additional one called *referee* only participates in voting. Compared to traditional three nodes setup, this is cheaper (referee resources demands are low) but availability is decreased. For details, see [Section F.30.3.3](#).

When a failed node is reconnected to the cluster, `multimaster` automatically fast-forwards the node to the actual state based on the Write-Ahead Log (WAL) data in the corresponding replication slot. If a node was excluded from the cluster, you can [add it back using `pg\_basebackup`](#).

To learn more about the `multimaster` internals, see [Section F.30.2](#).

F.30.1. Limitations

The `multimaster` extension takes care of the database replication in a fully automated way. You can perform write transactions on any node and work with temporary tables on each cluster node simultaneously. However, make sure to take the following replication restrictions into account:

- Microsoft Windows operating system is not supported.
- 1C solutions are not supported.
- `multimaster` can replicate only one database in a cluster. If it is required to replicate the contents of several databases, you can either transfer all data into different schemas within a single database or create a separate cluster for each database and set up `multimaster` for each cluster.
- [Large objects](#) are not supported. Although creating large objects is allowed, `multimaster` cannot replicate such objects, and their OIDs may conflict on different nodes, so their use is not recommended.
- Since `multimaster` is based on [logical replication and Paxos over three-phase commit protocol](#), its operation is highly affected by network latency. It is not recommended to set up a `multimaster` cluster with geographically distributed nodes.
- Using tables without primary keys can have negative impact on performance. In some cases, it can even lead to inability to restore a cluster node, so you should avoid replicating such tables with `multimaster`.
- Unlike in vanilla PostgreSQL, `read committed` isolation level can cause serialization failures on a multi-master cluster (with an SQLSTATE code '40001') if there are conflicting transactions from different nodes, so the application must be ready to retry transactions. *Serializable* isolation level works only with respect to local transactions on the current node.
- Sequence generation. To avoid conflicts between unique identifiers on different nodes, `multimaster` modifies the default behavior of sequence generators. By default, ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly. Thus, the generated sequence values are not monotonic. If it is critical to get a monotonically increasing sequence cluster-wide, you can set the `multimaster.monotonic_sequences` to `true`.
- Commit latency. In the current implementation of logical replication, `multimaster` sends data to subscriber nodes only after the local commit, so you have to wait for transaction processing twice: first on the local node, and then on all the other nodes simultaneously. In the case of a heavy-write transaction, this may result in a noticeable delay.
- Logical replication does not guarantee that a system object OID is the same on all cluster nodes, so OIDs for the same object may differ between `multimaster` cluster nodes. If your driver or application relies on OIDs, make sure that their use is restricted to connections to one and the same node to avoid errors. For example, the `Npgsql` driver may not work correctly with `multimaster` if

the `NpgsqlConnection.GlobalTypeMapper` method tries using OIDs in connections to different cluster nodes.

- Replicated non-conflicting transactions are applied on the receiving nodes in parallel, so such transactions may become visible on different nodes in different order.
- If `multimaster` is working under heavy load, and one of the nodes stops even for a short time, this node can fall far behind other nodes as they take the load in multiple threads, whereas the lagging node catches up in a single thread. In this case, you may need to unload other nodes in order to synchronize all the nodes.
- `CREATE INDEX CONCURRENTLY`, `REINDEX CONCURRENTLY`, `CREATE TABLESPACE`, and `DROP TABLESPACE` are not supported.
- `COMMIT AND CHAIN` feature is not supported.

F.30.2. Architecture

F.30.2.1. Replication

Since each server in a multi-master cluster can accept writes, any server can abort a transaction because of a concurrent update — in the same way as it happens on a single server between different backends. To ensure high availability and data consistency on all cluster nodes, `multimaster` uses [logical replication](#) and the three-phase commit protocol with transaction outcome determined by [Paxos consensus algorithm](#).

When Postgres Pro Enterprise loads the `multimaster` shared library, `multimaster` sets up a logical replication producer and consumer for each node, and hooks into the transaction commit pipeline. The typical data replication workflow consists of the following phases:

1. **PREPARE phase.** `multimaster` captures and implicitly transforms each `COMMIT` statement to a `PREPARE` statement. All the nodes that get the transaction via the replication protocol (*the cohort nodes*) send their vote for approving or declining the transaction to the backend process on the initiating node. This ensures that all the cohort can accept the transaction, and no write conflicts occur. For details on `PREPARE` transactions support in PostgreSQL, see the [PREPARE TRANSACTION](#) topic.
2. **PRECOMMIT phase.** If all the cohort nodes approve the transaction, the backend process sends a `PRECOMMIT` message to all the cohort nodes to express an intention to commit the transaction. The cohort nodes respond to the backend with the `PRECOMMITTED` message. In case of a failure, all the nodes can use this information to complete the transaction using a quorum-based voting procedure.
3. **COMMIT phase.** If `PRECOMMIT` is successful, the transaction is committed to all nodes.

If a node crashes or gets disconnected from the cluster between the `PREPARE` and `COMMIT` phases, the `PRECOMMIT` phase ensures that the survived nodes have enough information to complete the prepared transaction. The `PRECOMMITTED` messages help avoid the situation when the crashed node has already committed or aborted the transaction, but has not notified other nodes about the transaction status. In a two-phase commit (2PC), such a transaction would block resources (hold locks) until the recovery of the crashed node. Otherwise, data inconsistencies can appear in the database when the failed node is recovered, for example, if the failed node committed the transaction, but the survived node aborted it.

To complete the transaction, the backend must receive a response from the majority of the nodes. For example, for a cluster of $2N+1$ nodes, at least $N+1$ responses are required. Thus, `multimaster` ensures that your cluster is available for reads and writes while the majority of the nodes are connected, and no data inconsistencies occur in case of a node or connection failure.

F.30.2.2. Failure Detection and Recovery

Since `multimaster` allows writes to each node, it has to wait for responses about transaction acknowledgment from all the other nodes. Without special actions in case of a node failure, each commit would have to wait until the failed node recovery. To deal with such situations, `multimaster` periodically sends

heartbeats to check the node state and the connectivity between nodes. When several heartbeats to the node are lost in a row, this node is kicked out of the cluster to allow writes to the remaining alive nodes. You can configure the heartbeat frequency and the response timeout in the `multimaster.heartbeat_send_timeout` and `multimaster.heartbeat_recv_timeout` parameters, respectively.

For example, suppose a five-node multi-master cluster experienced a network failure that split the network into two isolated subnets, with two and three cluster nodes. Based on heartbeats propagation information, `multimaster` will continue accepting writes at each node in the bigger partition, and deny all writes in the smaller one. Thus, a cluster consisting of $2N+1$ nodes can tolerate N node failures and stay alive if any $N+1$ nodes are alive and connected to each other. You can also set up a two nodes cluster plus a lightweight referee node that does not hold the data, but acts as a tie-breaker during symmetric node partitioning. For details, see [Section F.30.3.3](#).

In case of a partial network split when different nodes have different connectivity, `multimaster` finds a fully connected subset of nodes and disconnects nodes outside of this subset. For example, in a three-node cluster, if node A can access both B and C, but node B cannot access node C, `multimaster` isolates node C to ensure that both A and B can work.

To preserve order of transactions on different nodes and thus data integrity, the decision to exclude or add back node(s) must be taken coherently. Generations which represent a subset of currently supposedly live nodes serve this purpose. Technically, generation is a pair `<n, members>` where n is unique number and `members` is subset of configured nodes. A node always lives in some generation and switches to the one with higher number as soon as it learns about its existence; generation numbers act as logical clocks/terms/epochs here. Each transaction is stamped during commit with current generation of the node it is being executed on. The transaction can be proposed to be committed only after it has been PREPARED on all its generation members. This allows to design the recovery protocol so that order of conflicting committed transactions is the same on all nodes. Node resides in generation in one of three states (can be shown with `mtm.status()`):

1. **ONLINE**: node is member of the generation and making transactions normally;
2. **RECOVERY**: node is member of the generation, but it must apply in recovery mode transactions from previous generations to become **ONLINE**;
3. **DEAD**: node will never be **ONLINE** in this generation;

For alive nodes, there is no way to distinguish between a failed node that stopped serving requests and a network-partitioned node that can be accessed by database users, but is unreachable for other nodes. If during commit of writing transaction some of current generation members are disconnected, transaction is rolled back according to generation rules. To avoid futile work, connectivity is also checked during transaction start; if you try to access an isolated node, `multimaster` returns an error message indicating the current status of the node. Thus, to prevent stale reads read-only queries are also forbidden. If you would like to continue using a disconnected node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension on this node, as explained in [Section F.30.4.5](#).

Each node maintains a data structure that keeps the information about the state of all nodes in relation to this node. You can get this data by calling the `mtm.status()` and the `mtm.nodes()` functions.

When a failed node connects back to the cluster, `multimaster` starts automatic recovery:

1. The reconnected node selects a cluster node which is **ONLINE** in the highest generation and starts catching up with the current state of the cluster based on the Write-Ahead Log (WAL).
2. When the node is caught up, it ballots for including itself in the next generation. Once generation is elected, commit of new transactions will start waiting for apply on the joining node.
3. When the rest of transactions till the switch to the new generation is applied, the reconnected node is promoted to the `online` state and included into the replication scheme.

The correctness of recovery protocol was verified with TLA+ model checker. You can find the model (and more detailed description) at [doc/specs](#) directory of the source code.

Automatic recovery requires presence of all WAL files generated after node failure. If a node is down for a long time and storing more WALs is unacceptable, you may have to exclude this node from the cluster and manually restore it from one of the working nodes using `pg_basebackup`. For details, see [Section F.30.4.3](#).

F.30.2.3. Multimaster Background Workers

`mtm-monitor`

Starts all other workers for a database managed with multimaster. This is the first worker loaded during multimaster boot. Each multimaster node has a single `mtm-monitor` worker. When a new node is added, `mtm-monitor` starts `mtm-logrep-receiver` and `mtm-dmq-receiver` workers to enable replication to this node. If a node is dropped, `mtm-monitor` stops `mtm-logrep-receiver` and `mtm-dmq-receiver` workers that have been serving the dropped node. Each `mtm-monitor` controls workers on its own node only.

`mtm-logrep-receiver`

Receives logical replication stream from a given peer node. During recovery, all received transactions are applied by `mtm-logrep-receiver`. During normal operation, `mtm-logrep-receiver` passes transactions to the pool of dynamic workers (see [mtm-logrep-receiver-dynworker](#)). The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

`mtm-dmq-receiver`

Receives acknowledgment for transactions sent to peers and checks for heartbeat timeouts. The number of `mtm-logrep-receiver` workers on each node corresponds to the number of peer nodes available.

`mtm-dmq-sender`

Collects acknowledgment for transactions applied on the current node and sends them to the corresponding [mtm-dmq-receiver](#) on the peer node. There is a single worker per Postgres Pro Enterprise instance.

`mtm-logrep-receiver-dynworker`

Dynamic pool worker for a given [mtm-logrep-receiver](#). Applies the replicated transaction received during normal operation. There are up to `multimaster.max_workers` workers per each peer node.

`mtm-resolver`

Performs Paxos to resolve unfinished transactions. This worker is only active during recovery or when connection with other nodes was lost. There is a single worker per Postgres Pro Enterprise instance.

`mtm-campaigner`

Ballots for new generations to exclude some node(s) or add myself. There is a single worker per Postgres Pro Enterprise instance.

`mtm-replier`

Responds to requests of [mtm-campaigner](#) and [mtm-resolver](#).

F.30.3. Installation and Setup

To use `multimaster`, you need to install Postgres Pro or Postgres Pro Enterprise on all nodes of your cluster. Postgres Pro includes all the required dependencies and extensions. For PostgreSQL follow build and install instructions at [readme.md](#).

F.30.3.1. Setting up a Multi-Master Cluster

Suppose you are setting up a cluster of three nodes, with `node1`, `node2`, and `node3` host names. After installing Postgres Pro Enterprise on all nodes, you need to initialize data directory on each node, as

explained in [Section 18.2](#). If you would like to set up a multi-master cluster for an already existing `mydb` database, you can load data from `mydb` to one of the nodes once the cluster is initialized, or you can load data to all new nodes before cluster initialization using any convenient mechanism, such as `pg_basebackup` or `pg_dump`.

Once the data directory is set up, complete the following steps on each cluster node:

1. Modify the `postgresql.conf` configuration file, as follows:

- Add `multimaster` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'multimaster'
```

Tip

If the `shared_preload_libraries` variable is already defined in `postgresql.auto.conf`, you will need to modify its value using the `ALTER SYSTEM` command. For details, see [Section 19.1.2](#). Note that in a multi-master cluster, the `ALTER SYSTEM` command only affects the configuration of the node from which it was run.

- Set up Postgres Pro Enterprise parameters related to replication:

```
wal_level = logical
max_connections = 100
max_prepared_transactions = 300 # max_connections * N
max_wal_senders = 10           # at least N
max_replication_slots = 10     # at least 2N
wal_sender_timeout = 0
```

where N is the number of nodes in your cluster.

You must change the replication level to `logical` as `multimaster` relies on logical replication. For a cluster of N nodes, enable at least N WAL sender processes and replication slots. Since `multimaster` implicitly adds a `PREPARE` phase to each `COMMIT` transaction, make sure to set the number of prepared transactions to $N * \text{max\_connections}$. `wal_sender_timeout` should be disabled as `multimaster` uses its custom logic for failure detection.

- Make sure you have enough background workers allocated for each node:

```
max_worker_processes = 250 # (N - 1) * (multimaster.max_workers + 1) + 5
```

For example, for a three-node cluster with `multimaster.max_workers = 100`, `multimaster` may need up to 207 background workers at peak times: five always-on workers (monitor, resolver, dmq-sender, campaigner, replier), one walreceiver per each peer node and up to 200 replication dynamic workers. When setting this parameter, remember that other modules may also use background workers at the same time.

- Depending on your network environment and usage patterns, you may want to tune other `multimaster` parameters. For details, see [Section F.30.3.2](#).

2. Start Postgres Pro Enterprise on all nodes.

3. Create database `mydb` and user `mtmuser` on each node:

```
CREATE USER mtmuser WITH SUPERUSER PASSWORD 'mtmuserpassword';
CREATE DATABASE mydb OWNER mtmuser;
```

If you are using password-based authentication, you may want to create a [password file](#).

You can omit this step if you already have a database you are going to replicate, but you are recommended to create a separate superuser for multi-master replication. The examples below assume that you are going to replicate the `mydb` database on behalf of `mtmuser`.

4. Allow replication of the `mydb` database to each cluster node on behalf of `mtmuser`, as explained in [Section 20.1](#). Make sure to use the [authentication method](#) that satisfies your security requirements. For example, `pg_hba.conf` might have the following lines on `node1`:

```
host replication mtmuser node2 md5
host mydb mtmuser node2 md5
host replication mtmuser node3 md5
host mydb mtmuser node3 md5
```

5. Connect to any node on behalf of the `mtmuser` database user, create the `multimaster` extension in the `mydb` database and run `mtm.init_cluster()`, specifying the connection string to the current node as the first argument and an array of connection strings to the other nodes as the second argument.

For example, if you would like to connect to `node1`, run:

```
CREATE EXTENSION multimaster;
SELECT mtm.init_cluster('dbname=mydb user=mtmuser host=node1',
  '{"dbname=mydb user=mtmuser host=node2", "dbname=mydb user=mtmuser host=node3"}');
```

6. To ensure that `multimaster` is enabled, you can run the `mtm.status()` and `mtm.nodes()` functions:

```
SELECT * FROM mtm.status();
SELECT * FROM mtm.nodes();
```

If `status` is equal to `online` and all nodes are present in the `mtm.nodes` output, your cluster is successfully configured and ready to use.

Tip

If you have any data that must be present on one of the nodes only, you can exclude a particular table from replication, as follows:

```
SELECT mtm.make_table_local('table_name')
```

F.30.3.2. Tuning Configuration Parameters

While you can use `multimaster` in the default configuration, you may want to tune several parameters for faster failure detection or more reliable automatic recovery.

F.30.3.2.1. Setting Timeout for Failure Detection

To check availability of the peer nodes, `multimaster` periodically sends heartbeat packets to all nodes. You can define the timeout for failure detection with the following variables:

- The `multimaster.heartbeat_send_timeout` variable defines the time interval between the heartbeats. By default, this variable is set to 200ms.
- The `multimaster.heartbeat_rcv_timeout` variable sets the timeout for the response. If no heartbeats are received during this time, the node is assumed to be disconnected and is excluded from the cluster. By default, this variable is set to 2000ms.

It's a good idea to set `multimaster.heartbeat_send_timeout` based on typical ping latencies between the nodes. Small `rcv/send` ratio decreases the time of failure detection, but increases the probability of false-positive failure detection. When setting this parameter, take into account the typical packet loss ratio between your cluster nodes.

F.30.3.3. 2+1 Mode: Setting up a Standalone Referee Node

By default, `multimaster` uses a majority-based algorithm to determine whether the cluster nodes have a quorum: a cluster can only continue working if the majority of its nodes are alive and can access each other. Majority-based approach is pointless for two nodes cluster: if one of them fails, another one becomes inaccessible. There is a special 2+1 or referee mode which trades less hardware resources by

decreasing availability: two nodes hold full copy of data, and separate referee node participates only in voting, acting as a tie-breaker.

If one node goes down, another one requests referee grant (elects referee-approved generation with single node). Once the grant is received, it continues to work normally. If offline node gets up, it recovers and elects full generation containing both nodes, essentially removing the grant - this allows the node to get it in its turn later. While the grant is issued, it can't be given to another node until full generation is elected and excluded node recovers. This ensures data loss doesn't happen by the price of availability: in this setup two nodes (one normal and one referee) can be alive but cluster might be still unavailable if the referee winner is down, which is impossible with classic three nodes configuration.

The referee node does not store any cluster data, so it is not resource-intensive and can be configured on virtually any system with Postgres Pro Enterprise installed.

To avoid split-brain problems, you must have only a single referee in your cluster.

To set up a referee for your cluster:

1. Install Postgres Pro Enterprise on the node you are going to make a referee and create the `referee` extension:

```
CREATE EXTENSION referee;
```

2. Make sure the `pg_hba.conf` file allows access to the referee node.
3. Set up the nodes that will hold cluster data following the instructions in [Section F.30.3.1](#).
4. On all data nodes, specify the referee connection string in the `postgresql.conf` file:

```
multimaster.referee_connstring = connstring
```

where *connstring* holds [libpq options](#) required to access the referee.

The first subset of nodes that gets connected to the referee wins the voting and starts working. The other nodes have to go through the recovery process to catch up with them and join the cluster. Under heavy load, the recovery can take unpredictably long, so it is recommended to wait for all data nodes going online before switching on the load when setting up a new cluster. Once all the nodes get online, the referee discards the voting result, and all data nodes start operating together.

In case of any failure, the voting mechanism is triggered again. At this time, all nodes appear to be offline for a short period of time to allow the referee to choose a new winner, so you can see the following error message when trying to access the cluster: `[multimaster] node is not online: current status is "disabled"`.

F.30.4. Multi-Master Cluster Administration

- [Monitoring the Cluster Status](#)
- [Accessing Disabled Nodes](#)
- [Adding New Nodes to the Cluster](#)
- [Removing Nodes from the Cluster](#)
- [Checking Data Consistency Across Cluster Nodes](#)

F.30.4.1. Monitoring Cluster Status

`multimaster` provides several functions to check the current cluster state.

To check node-specific information, use `mtm.status()`:

```
SELECT * FROM mtm.status();
```

To get the list of all nodes in the cluster together with their status, use `mtm.nodes()`:

```
SELECT * FROM mtm.nodes();
```

For details on all the returned information, see [Section F.30.5.2](#).

F.30.4.2. Accessing Disabled Nodes

If a cluster node is disabled, any attempt to read or write data on this node raises an error by default. If you need to access the data on a disabled node, you can override this behavior at connection time by setting the `application_name` parameter to `mtm_admin`. In this case, you can run read and write queries on this node without multimaster supervision.

F.30.4.3. Adding New Nodes to the Cluster

With the `multimaster` extension, you can add or drop cluster nodes. Before adding node, stop the load and ensure (with `mtm.status()`) that all nodes are `online`. When adding a new node, you need to load all the data to this node using `pg_basebackup` from any cluster node, and then start this node.

Suppose we have a working cluster of three nodes, with `node1`, `node2`, and `node3` host names. To add `node4`, follow these steps:

1. Figure out the required connection string to access the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string can be `"dbname=mydb user=mtmuser host=node4"`.
2. In `psql` connected to any alive node, run:

```
SELECT mtm.add_node('dbname=mydb user=mtmuser host=node4');
```

This command changes the cluster configuration on all nodes and creates replication slots for the new node. It also returns `node_id` of the new node, which will be required to complete the setup.

3. Go to the new node and clone all the data from one of the alive nodes to this node:

```
pg_basebackup -D datadir -h node1 -U mtmuser -c fast -v
```

`pg_basebackup` copies the entire data directory from `node1`, together with configuration settings, and prints the last LSN replayed from WAL, such as `'0/12D357F0'`. This value will be required to complete the setup.

4. Configure the new node to boot with `recovery_target=immediate` to prevent redo past the point where replication will begin. Add to `postgresql.conf`:

```
restore_command = 'false'
recovery_target = 'immediate'
recovery_target_action = 'promote'
```

And create `recovery.signal` file in the data directory.

5. Start Postgres Pro Enterprise on the new node.
6. In `psql` connected to the node used to take the base backup, run:

```
SELECT mtm.join_node(4, '0/12D357F0');
```

where 4 is the `node_id` returned by the `mtm.add_node()` function call and `'0/12D357F0'` is the LSN value returned by `pg_basebackup`.

F.30.4.4. Removing Nodes from the Cluster

Before removing node, stop the load and ensure (with `mtm.status()`) that all nodes (except the ones to be dropped) are `online`. Shut down the nodes you are going to remove. To remove the node from the cluster:

1. Run the `mtm.nodes()` function to learn the ID of the node to be removed:

```
SELECT * FROM mtm.nodes();
```

2. Run the `mtm.drop_node()` function with this node ID as a parameter:

```
SELECT mtm.drop_node(3);
```

This will delete replication slots for node 3 on all cluster nodes and stop replication to this node.

If you would like to return the node to the cluster later, you will have to add it as a new node, as explained in [Section F.30.4.3](#).

F.30.4.5. Uninstalling the multimaster Extension

If you would like to continue using the node that has been removed from the cluster in the standalone mode, you have to drop the `multimaster` extension on this node and clean up all `multimaster`-related subscriptions and uncommitted transactions to ensure that the node is no longer associated with the cluster.

1. Remove `multimaster` from [shared_preload_libraries](#) and restart Postgres Pro Enterprise.
2. Delete the `multimaster` extension and publication:

```
DROP EXTENSION multimaster;  
DROP PUBLICATION multimaster;
```

3. Review the list of existing subscriptions using the `\dRs` command and delete each subscription that starts with the `mtm_sub_` prefix:

```
\dRs  
DROP SUBSCRIPTION mtm_sub_subscription_name;
```

4. Review the list of existing replication slots and delete each slot that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_slots;  
SELECT pg_drop_replication_slot('mtm_slot_name');
```

5. Review the list of existing replication origins and delete each origin that starts with the `mtm_` prefix:

```
SELECT * FROM pg_replication_origin;  
SELECT pg_replication_origin_drop('mtm_origin_name');
```

6. Review the list of prepared transaction left, if any:

```
SELECT * FROM pg_prepared_xacts;
```

You have to commit or abort these transactions by running `ABORT PREPARED transaction_id` or `COMMIT PREPARED transaction_id`, respectively.

Once all these steps are complete, you can start using the node in the standalone mode, if required.

F.30.4.6. Checking Data Consistency Across Cluster Nodes

You can check that the data is the same on all cluster nodes using the `mtm.check_query(query_text)` function.

As a parameter, this function takes the text of a query you would like to run for data comparison. When you call this function, it takes a consistent snapshot of data on each cluster node and runs this query against the captured snapshots. The query results are compared between pairs of nodes. If there are no differences, this function returns `true`. Otherwise, it reports the first detected difference in a warning and returns `false`.

To avoid false-positive results, always use the `ORDER BY` clause in your test query. For example, suppose you would like to check that the data in a `my_table` is the same on all cluster nodes. Compare the results of the following queries:

```
postgres=# SELECT mtm.check_query('SELECT * FROM my_table ORDER BY id');  
check_query  
-----  
t
```

```
(1 row)

postgres=# SELECT mtm.check_query('SELECT * FROM my_table');
WARNING: mismatch in column 'b' of row 0: 256 on node0, 255 on node1
check_query
-----
f
(1 row)
```

Even though the data is the same, the second query reports an issue because the order of the returned data differs between cluster nodes.

F.30.5. Reference

F.30.5.1. Configuration Parameters

`multimaster.heartbeat_recv_timeout`

Timeout, in milliseconds. If no heartbeat message is received from the node within this timeframe, the node is excluded from the cluster.

Default: 2000 ms

`multimaster.heartbeat_send_timeout`

Time interval between heartbeat messages, in milliseconds. An arbiter process broadcasts heartbeat messages to all nodes to detect connection problems.

Default: 200 ms

`multimaster.max_workers`

The maximum number of `walreceiver` workers per peer node.

Important

This parameter should be used with caution. If the number of simultaneous transactions in the whole cluster is bigger than the provided value, it can lead to undetected deadlocks.

Default: 100

`multimaster.monotonic_sequences`

Defines the sequence generation mode for unique identifiers. This variable can take the following values:

- `false` (default) — ID generation on each node is started with this node number and is incremented by the number of nodes. For example, in a three-node cluster, 1, 4, and 7 IDs are allocated to the objects written onto the first node, while 2, 5, and 8 IDs are reserved for the second node. If you change the number of nodes in the cluster, the incrementation interval for new IDs is adjusted accordingly.
- `true` — the generated sequence increases monotonically cluster-wide. ID generation on each node is started with this node number and is incremented by the number of nodes, but the values are omitted if they are smaller than the already generated IDs on another node. For example, in a three-node cluster, if 1, 4 and 7 IDs are already allocated to the objects on the first node, 2 and 5 IDs will be omitted on the second node. In this case, the first ID on the second node is 8. Thus, the next generated ID is always higher than the previous one, regardless of the cluster node.

Default: `false`

`multimaster.referee_connstring`

Connection string to access the referee node. You must set this parameter on all cluster nodes if the referee is set up.

`multimaster.remote_functions`

Provides a comma-separated list of function names that should be executed remotely on all multimaster nodes instead of replicating the result of their work.

`multimaster.trans_spill_threshold`

The maximal size of transaction, in kB. When this threshold is reached, the transaction is written to the disk.

Default: 100MB

`multimaster.break_connection`

Break connection with clients connected to the node if this node disconnects from the cluster. If this variable is set to `false`, the client stays connected to the node but receives an error that the node is disabled.

Default: `false`

`multimaster.connect_timeout`

Maximum time to wait while connecting, in seconds. Zero, negative, or not specified means wait indefinitely. The minimum allowed timeout is 2 seconds, therefore a value of 1 is interpreted as 2.

Default: 0

`multimaster.ignore_tables_without_pk`

Do not replicate tables without primary key. When `false`, such tables are replicated.

Default: `false`

`multimaster.syncpoint_interval`

Amount of WAL generated between synchronization points.

Default: 10 MB

`multimaster.binary_basetypes`

Send data of built-in types in binary format.

Default: `true`

`multimaster.wait_peer_commits`

Wait until all peers commit the transaction before the command returns a success indication to the client.

Default: `true`

`multimaster.deadlock_prevention`

Manage prevention of transaction deadlocks that can occur when the same tuple is updated or deleted on different nodes simultaneously. If set to `off`, deadlock prevention is disabled.

If set to `simple`, the conflicting transactions are rejected. This setting may be used in any setup.

If set to `smart`, a specific algorithm is used to provide best resource availability by selectively committing or rejecting transactions. This is recommended for a setup of [two nodes and a referee](#). In

three node setups, deadlocks are still possible. If there are more than four nodes, all conflicting transactions are rejected, just as with `simple`.

Default: `off`

F.30.5.2. Functions

```
mtm.init_cluster(my_conninfo text, peers_conninfo text[])
```

Initializes cluster configuration on all nodes. It connects the current node to all nodes listed in `peers_conninfo` and creates the `multimaster` extension, replication slots, and replication origins on each node. Run this function once all the nodes are running and can accept connections.

Arguments:

- `my_conninfo` — connection string to the node on which you are running this function. Peer nodes use this string to connect back to this node.
- `peers_conninfo` — an array of connection strings to all the other nodes to be added to the cluster.

```
mtm.add_node(connstr text)
```

Adds a new node to the cluster. This function should be called before loading data to this node using `pg_basebackup`. `mtm.add_node` creates the required replication slots for a new node, so you can add a node while the cluster is under load.

Arguments:

- `connstr` — connection string for the new node. For example, for the database `mydb`, user `mtmuser`, and the new node `node4`, the connection string is `"dbname=mydb user=mtmuser host=node4"`.

```
mtm.join_node(node_id int, backup_end_lsn pg_lsn)
```

Completes the cluster setup after adding a new node. This function should be called after the added node has been started.

Arguments:

- `node_id` — ID of the node to add to the cluster. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

`backup_end_lsn` — the last LSN of the base backup copied to the new node. This LSN will be used as the starting point for data replication once the node joins the cluster.

```
mtm.drop_node(node_id integer)
```

Excludes a node from the cluster.

If you would like to continue using this node outside of the cluster in the standalone mode, you have to uninstall the `multimaster` extension from this node, as explained in [Section F.30.4.5](#).

Arguments:

- `node_id` — ID of the node being dropped. It corresponds to the value in the `id` column returned by `mtm.nodes()`.

```
mtm.alter_sequences()
```

Fixes unique identifiers on all cluster nodes. This may be required after restoring all nodes from a single base backup.

`mtm.status()`

Shows the status of the `multimaster` extension on the current node. Returns a tuple of the following values:

- `my_node_id`, `int` — ID of this node.
- `status`, `text` — status of the node. Possible values are: `online`, `recovery`, `catchup`, `disabled` (need to recover, but not yet clear from whom), `isolated` (online in current generation, but some members are disconnected).
- `connected`, `int[]` — array of peer IDs connected to this node.
- `gen_num`, `int8` — current generation number.
- `gen_members`, `int[]` — array of current generation members node IDs.
- `gen_members_online`, `int[]` — array of current generation members node IDs which are online in it.
- `gen_configured`, `int[]` — array of node IDs configured in current generation.

`mtm.nodes()`

Shows the information on all nodes in the cluster. Returns a tuple of the following values:

- `id`, `integer` — node ID.
- `conninfo`, `text` — connection string to this node.
- `is_self`, `boolean` — is it me?
- `enabled`, `boolean` — is this node online in current generation?
- `connected`, `boolean` — shows whether the node is connected to our node.
- `sender_pid`, `integer` — WAL sender process ID.
- `receiver_pid`, `integer` — WAL receiver process ID.
- `n_workers`, `text` — number of started dynamic apply workers from this node.
- `receiver_mode`, `text` — in which mode receiver from this node works. Possible values are: `disabled`, `recovery`, `normal`.

`mtm.make_table_local(relation regclass)`

Stops replication for the specified table.

Arguments:

- `relation` — the table you would like to exclude from the replication scheme.

`mtm.check_query(query_text text)`

Checks data consistency across cluster nodes. This function takes a snapshot of the current state of each node, runs the specified query against these snapshots, and compares the results. If the results are different between any two nodes, displays a warning with the first found issue and returns `false`. Otherwise, returns `true`.

Arguments:

- `query_text` — the query you would like to run on all nodes for data comparison. To avoid false-positive results, always use the `ORDER BY` clause in the test query.

`mtm.get_snapshots()`

Takes a snapshot of data on each cluster node and returns the snapshot ID. The snapshots remain available until the `mtm.free_snapshots()` is called, or the current session is terminated. This function is used by the [mtm.check_query\(query_text\)](#), there is no need to call it manually.

```
mtm.free_snapshots()
```

Removes data snapshots taken by the `mtm.get_snapshots()` function. This function is used by the [mtm.check_query\(query_text\)](#), there is no need to call it manually.

F.30.6. Compatibility

F.30.6.1. Local and Global DDL Statements

By default, any DDL statement is executed on all cluster nodes, except the following statements that can only act locally on a given node:

- ALTER SYSTEM
- CREATE DATABASE
- DROP DATABASE
- REINDEX
- CHECKPOINT
- CLUSTER
- LOAD
- LISTEN
- CHECKPOINT
- NOTIFY

F.30.7. Authors

Postgres Professional, Moscow, Russia.

F.30.7.1. Credits

The replication mechanism is based on logical decoding and an earlier version of the `pglogical` extension provided for community by the 2ndQuadrant team.

The Paxos consensus algorithm is described at:

- Leslie Lamport. [The Part-Time Parliament](#)

Parallel replication and recovery mechanism is similar to the one described in:

- Odorico M. Mendizabal, et al. [Checkpointing in Parallel State-Machine Replication](#).

F.31. online_analyze

The `online_analyze` module provides a set of features that immediately update statistics after INSERT, UPDATE, DELETE, or SELECT INTO operations for the affected tables.

Note

This extension cannot be used together with autonomous transactions or while built-in connection pooling is enabled.

F.31.1. Module Loading

To use `online_analyze` module, load the shared library:

```
LOAD 'online_analyze';
```

F.31.2. Module Configuration

You can configure `online_analyze` using the following custom variables (default values are shown):

- `online_analyze.enable = on`

Enables `online_analyze`.

- `online_analyze.verbose = on`

Executes `ANALYZE VERBOSE`.

Note

Since `verbose` is a reserved SQL key word, this parameter has to be double-quoted when used in SQL queries. For example:

```
ALTER SYSTEM SET "online_analyze.verbose" = 'off';
```

- `online_analyze.scale_factor = 0.1`

Fraction of table size to start online analysis (similar to [autovacuum_analyze_scale_factor](#)).

- `online_analyze.threshold = 50`

Minimum number of row updates before starting online analysis (similar to [autovacuum_analyze_threshold](#)).

- `online_analyze.min_interval = 10000`

Minimum time interval between `ANALYZE` calls per table, in milliseconds.

- `online_analyze.table_type = "all"`

Type(s) of tables for online analysis. Possible values are: `all`, `persistent`, `temporary`, `none`.

- `online_analyze.exclude_tables = ""`

List of tables to exclude from online analysis.

- `online_analyze.include_tables = ""`

List of tables to include in online analysis (`online_analyze.include_tables` overrides `online_analyze.exclude_tables`).

- `online_analyze.local_tracking = off`

Enables per-backend tracking for temporary tables by `online_analyze`. When this variable is set to `off`, `online_analyze` uses the default system statistics for temporary tables.

- `online_analyze.lower_limit = 0`

Minimum number of rows in a table required to trigger `online_analyze`.

- `online_analyze.capacity_threshold = 100000`

Maximum number of temporary tables to store in local cache.

F.31.3. Authors

Teodor Sigaev <teodor@sigaev.ru>

F.32. pageinspect

The `pageinspect` module provides functions that allow you to inspect the contents of database pages at a low level, which is useful for debugging purposes. All of these functions may be used only by superusers.

F.32.1. General Functions

`get_raw_page(relname text, fork text, blkno int)` returns `bytea`

`get_raw_page` reads the specified block of the named relation and returns a copy as a `bytea` value. This allows a single time-consistent copy of the block to be obtained. *fork* should be 'main' for the main data fork, 'fsm' for the free space map, 'vm' for the visibility map, or 'init' for the initialization fork.

`get_raw_page(relname text, blkno int)` returns `bytea`

A shorthand version of `get_raw_page`, for reading from the main fork. Equivalent to `get_raw_page(relname, 'main', blkno)`

`page_header(page bytea)` returns `record`

`page_header` shows fields that are common to all Postgres Pro heap and index pages.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM page_header(get_raw_page('pg_class', 0));
   lsn    | checksum | flags  | lower | upper | special | pagesize | version |
   ----+-----+-----+-----+-----+-----+-----+-----+
0/24A1B50 |         0 |      1 |   232 |   368 |       8192 |   8192 |         4 |
0 |         0 |         0
```

The returned columns correspond to the fields in the `PageHeaderData` struct.

The `checksum` field is the checksum stored in the page, which might be incorrect if the page is somehow corrupted. If data checksums are not enabled for this instance, then the value stored is meaningless.

`page_checksum(page bytea, blkno int4)` returns `smallint`

`page_checksum` computes the checksum for the page, as if it was located at the given block.

A page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT page_checksum(get_raw_page('pg_class', 0), 0);
 page_checksum
-----
        13443
```

Note that the checksum depends on the block number, so matching block numbers should be passed (except when doing esoteric debugging).

The checksum computed with this function can be compared with the `checksum` result field of the function `page_header`. If data checksums are enabled for this instance, then the two values should be equal.

`fsm_page_contents(page bytea)` returns `text`

`fsm_page_contents` shows the internal node structure of a FSM page. For example:

```
test=# SELECT fsm_page_contents(get_raw_page('pg_class', 'fsm', 0));
```

The output is a multiline string, with one line per node in the binary tree within the page. Only those nodes that are not zero are printed. The so-called "next" pointer, which points to the next slot to be returned from the page, is also printed.

F.32.2. Heap Functions

`heap_page_items`(page bytea) returns setof record

`heap_page_items` shows all line pointers on a heap page. For those line pointers that are in use, tuple headers as well as tuple raw data are also shown. All tuples are shown, whether or not the tuples were visible to an MVCC snapshot at the time the raw page was copied.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_items(get_raw_page('pg_class', 0));
```

The `heap_tuple_infomask_flags` function can be used to unpack the flag bits of `t_infomask` and `t_infomask2` for heap tuples.

`tuple_data_split`(rel_oid oid, t_data bytea, t_infomask integer, t_infomask2 integer, t_bits text [, do_detoast bool]) returns bytea[]

`tuple_data_split` splits tuple data into attributes in the same way as backend internals.

```
test=# SELECT tuple_data_split('pg_class'::regclass, t_data, t_infomask,
    t_infomask2, t_bits) FROM heap_page_items(get_raw_page('pg_class', 0));
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

If `do_detoast` is true, attributes will be detoasted as needed. Default value is false.

`heap_page_item_attrs`(page bytea, rel_oid regclass [, do_detoast bool]) returns setof record

`heap_page_item_attrs` is equivalent to `heap_page_items` except that it returns tuple raw data as an array of attributes that can optionally be detoasted by `do_detoast` which is false by default.

A heap page image obtained with `get_raw_page` should be passed as argument. For example:

```
test=# SELECT * FROM heap_page_item_attrs(get_raw_page('pg_class', 0),
    'pg_class'::regclass);
```

`heap_tuple_infomask_flags`(t_infomask integer, t_infomask2 integer) returns record

`heap_tuple_infomask_flags` decodes the `t_infomask` and `t_infomask2` returned by `heap_page_items` into a human-readable set of arrays made of flag names, with one column for all the flags and one column for combined flags. For example:

```
test=# SELECT t_ctid, raw_flags, combined_flags
    FROM heap_page_items(get_raw_page('pg_class', 0)),
    LATERAL heap_tuple_infomask_flags(t_infomask, t_infomask2)
    WHERE t_infomask IS NOT NULL OR t_infomask2 IS NOT NULL;
```

This function should be called with the same arguments as the return attributes of `heap_page_items`.

Combined flags are displayed for source-level macros that take into account the value of more than one raw bit, such as `HEAP_XMIN_FROZEN`.

F.32.3. B-Tree Functions

`bt_metap`(relnname text) returns record

`bt_metap` returns information about a B-tree index's metapage. For example:

```
test=# SELECT * FROM bt_metap('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
magic                | 340322
version              | 4
```

```

root          | 1
level         | 0
fastroot      | 1
fastlevel     | 0
oldest_xact   | 582
last_cleanup_num_tuples | 1000
allequalimage | f

```

`bt_page_stats(relname text, blkno int)` returns record

`bt_page_stats` returns summary information about single pages of B-tree indexes. For example:

```

test=# SELECT * FROM bt_page_stats('pg_cast_oid_index', 1);
-[ RECORD 1 ]-+-----
blkno         | 1
type          | 1
live_items    | 224
dead_items    | 0
avg_item_size | 16
page_size     | 8192
free_size     | 3668
btpo_prev     | 0
btpo_next     | 0
btpo          | 0
btpo_flags    | 3

```

`bt_page_items(relname text, blkno int)` returns setof record

`bt_page_items` returns detailed information about all of the items on a B-tree index page. For example:

```

test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
FROM bt_page_items('tenk2_hundred', 5);
 itemoffset | ctid      | itemlen | nulls | vars | data                                     | dead | htid | some_tids
-----+-----+-----+-----+-----+-----+-----+-----+-----
1 | (16,1)    | 16 | f | f | 30 00 00 00 00 00 00 00 00 00 00 00 | f |
2 | (16,8292) | 616 | f | f | 24 00 00 00 00 00 00 00 00 00 00 00 | f |
(1,6) | {"(1,6)","(10,22)"} | 3 | (16,8292) | 616 | f | 25 00 00 00 00 00 00 00 00 00 00 00 | f |
(1,18) | {"(1,18)","(4,22)"} | 4 | (16,8292) | 616 | f | 26 00 00 00 00 00 00 00 00 00 00 00 | f |
(4,18) | {"(4,18)","(6,17)"} | 5 | (16,8292) | 616 | f | 27 00 00 00 00 00 00 00 00 00 00 00 | f |
(1,2) | {"(1,2)","(1,19)"} | 6 | (16,8292) | 616 | f | 28 00 00 00 00 00 00 00 00 00 00 00 | f |
(2,24) | {"(2,24)","(4,11)"} | 7 | (16,8292) | 616 | f | 29 00 00 00 00 00 00 00 00 00 00 00 | f |
(2,17) | {"(2,17)","(11,2)"} | 8 | (16,8292) | 616 | f | 2a 00 00 00 00 00 00 00 00 00 00 00 | f |
(0,25) | {"(0,25)","(3,20)"} | 9 | (16,8292) | 616 | f | 2b 00 00 00 00 00 00 00 00 00 00 00 | f |
(0,10) | {"(0,10)","(0,14)"} | 10 | (16,8292) | 616 | f | 2c 00 00 00 00 00 00 00 00 00 00 00 | f |
(1,3) | {"(1,3)","(3,9)"} | 11 | (16,8292) | 616 | f | 2d 00 00 00 00 00 00 00 00 00 00 00 | f |
(6,28) | {"(6,28)","(11,1)"}

```

```

      12 | (16,8292) |      616 | f      | f      | 2e 00 00 00 00 00 00 00 | f      |
(0,27) | {"(0,27)", "(1,13)"}
      13 | (16,8292) |      616 | f      | f      | 2f 00 00 00 00 00 00 00 | f      |
(4,17) | {"(4,17)", "(4,21)"}
(13 rows)

```

This is a B-tree leaf page. All tuples that point to the table happen to be posting list tuples (all of which store a total of 100 6 byte TIDs). There is also a “high key” tuple at `itemoffset` number 1. `ctid` is used to store encoded information about each tuple in this example, though leaf page tuples often store a heap TID directly in the `ctid` field instead. `tids` is the list of TIDs stored as a posting list.

In an internal page (not shown), the block number part of `ctid` is a “downlink”, which is a block number of another page in the index itself. The offset part (the second number) of `ctid` stores encoded information about the tuple, such as the number of columns present (suffix truncation may have removed unneeded suffix columns). Truncated columns are treated as having the value “minus infinity”.

`htid` shows a heap TID for the tuple, regardless of the underlying tuple representation. This value may match `ctid`, or may be decoded from the alternative representations used by posting list tuples and tuples from internal pages. Tuples in internal pages usually have the implementation level heap TID column truncated away, which is represented as a NULL `htid` value.

Note that the first item on any non-rightmost page (any page with a non-zero value in the `btpo_next` field) is the page's “high key”, meaning its `data` serves as an upper bound on all items appearing on the page, while its `ctid` field does not point to another block. Also, on internal pages, the first real data item (the first item that is not a high key) reliably has every column truncated away, leaving no actual value in its `data` field. Such an item does have a valid downlink in its `ctid` field, however.

For more details about the structure of B-tree indexes, see [Section 63.4.1](#). For more details about deduplication and posting lists, see [Section 63.4.2](#).

`bt_page_items(page bytea)` returns `setof record`

It is also possible to pass a page to `bt_page_items` as a `bytea` value. A page image obtained with `get_raw_page` should be passed as argument. So the last example could also be rewritten like this:

```

test=# SELECT itemoffset, ctid, itemlen, nulls, vars, data, dead, htid, tids[0:2] AS
some_tids
      FROM bt_page_items(get_raw_page('tenk2_hundred', 5));
 itemoffset |      ctid      | itemlen | nulls | vars |      data      | dead |
 htid      |      some_tids
-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+-----+-----+-----+-----+-----+-----+
      1 | (16,1)      |      16 | f      | f      | 30 00 00 00 00 00 00 00 |      |
      |
      2 | (16,8292) |      616 | f      | f      | 24 00 00 00 00 00 00 00 | f      |
(1,6) | {"(1,6)", "(10,22)"}
      3 | (16,8292) |      616 | f      | f      | 25 00 00 00 00 00 00 00 | f      |
(1,18) | {"(1,18)", "(4,22)"}
      4 | (16,8292) |      616 | f      | f      | 26 00 00 00 00 00 00 00 | f      |
(4,18) | {"(4,18)", "(6,17)"}
      5 | (16,8292) |      616 | f      | f      | 27 00 00 00 00 00 00 00 | f      |
(1,2)  | {"(1,2)", "(1,19)"}
      6 | (16,8292) |      616 | f      | f      | 28 00 00 00 00 00 00 00 | f      |
(2,24) | {"(2,24)", "(4,11)"}
      7 | (16,8292) |      616 | f      | f      | 29 00 00 00 00 00 00 00 | f      |
(2,17) | {"(2,17)", "(11,2)"}
      8 | (16,8292) |      616 | f      | f      | 2a 00 00 00 00 00 00 00 | f      |
(0,25) | {"(0,25)", "(3,20)"}
      9 | (16,8292) |      616 | f      | f      | 2b 00 00 00 00 00 00 00 | f      |
(0,10) | {"(0,10)", "(0,14)"}

```

```

      10 | (16,8292) |      616 | f      | f      | 2c 00 00 00 00 00 00 00 | f      |
(1,3)  | {"(1,3)","(3,9)"}
      11 | (16,8292) |      616 | f      | f      | 2d 00 00 00 00 00 00 00 | f      |
(6,28) | {"(6,28)","(11,1)"}
      12 | (16,8292) |      616 | f      | f      | 2e 00 00 00 00 00 00 00 | f      |
(0,27) | {"(0,27)","(1,13)"}
      13 | (16,8292) |      616 | f      | f      | 2f 00 00 00 00 00 00 00 | f      |
(4,17) | {"(4,17)","(4,21)"}
(13 rows)

```

All the other details are the same as explained in the previous item.

F.32.4. BRIN Functions

`brin_page_type(page bytea)` returns text

`brin_page_type` returns the page type of the given BRIN index page, or throws an error if the page is not a valid BRIN page. For example:

```

test=# SELECT brin_page_type(get_raw_page('brinidx', 0));
brin_page_type
-----
meta

```

`brin_metapage_info(page bytea)` returns record

`brin_metapage_info` returns assorted information about a BRIN index metapage. For example:

```

test=# SELECT * FROM brin_metapage_info(get_raw_page('brinidx', 0));
 magic      | version | pagesperpage | lastrevmappage
-----+-----+-----+-----
0xA8109CFA |      1  |           4  |           2

```

`brin_revmap_data(page bytea)` returns setof tid

`brin_revmap_data` returns the list of tuple identifiers in a BRIN index range map page. For example:

```

test=# SELECT * FROM brin_revmap_data(get_raw_page('brinidx', 2)) LIMIT 5;
pages
-----
(6,137)
(6,138)
(6,139)
(6,140)
(6,141)

```

`brin_page_items(page bytea, index oid)` returns setof record

`brin_page_items` returns the data stored in the BRIN data page. For example:

```

test=# SELECT * FROM brin_page_items(get_raw_page('brinidx', 5),
                                     'brinidx')
      ORDER BY blknum, attnum LIMIT 6;
 itemoffset | blknum | attnum | allnulls | hasnulls | placeholder | value
-----+-----+-----+-----+-----+-----+-----
      137  |      0 |      1 | t        | f        | f          |
      137  |      0 |      2 | f        | f        | f          | {1 .. 88}
      138  |      4 |      1 | t        | f        | f          |
      138  |      4 |      2 | f        | f        | f          | {89 .. 176}
      139  |      8 |      1 | t        | f        | f          |
      139  |      8 |      2 | f        | f        | f          | {177 .. 264}

```

The returned columns correspond to the fields in the `BrinMemTuple` and `BrinValues` structs.

F.32.5. GIN Functions

`gin_metapage_info(page bytea)` returns record

`gin_metapage_info` returns information about a GIN index metapage. For example:

```
test=# SELECT * FROM gin_metapage_info(get_raw_page('gin_index', 0));
-[ RECORD 1 ]-----+-----
pending_head      | 4294967295
pending_tail      | 4294967295
tail_free_size    | 0
n_pending_pages   | 0
n_pending_tuples  | 0
n_total_pages     | 7
n_entry_pages     | 6
n_data_pages      | 0
n_entries         | 693
version           | 2
```

`gin_page_opaque_info(page bytea)` returns record

`gin_page_opaque_info` returns information about a GIN index opaque area, like the page type. For example:

```
test=# SELECT * FROM gin_page_opaque_info(get_raw_page('gin_index', 2));
 rightlink | maxoff | flags
-----+-----+-----
          5 |        0 | {data,leaf,compressed}
(1 row)
```

`gin_leafpage_items(page bytea)` returns setof record

`gin_leafpage_items` returns information about the data stored in a GIN leaf page. For example:

```
test=# SELECT first_tid, nbytes, tids[0:5] AS some_tids
       FROM gin_leafpage_items(get_raw_page('gin_test_idx', 2));
 first_tid | nbytes | some_tids
-----+-----+-----
(8,41)    | 244    | {"(8,41)","(8,43)","(8,44)","(8,45)","(8,46)"}
(10,45)   | 248    | {"(10,45)","(10,46)","(10,47)","(10,48)","(10,49)"}
(12,52)   | 248    | {"(12,52)","(12,53)","(12,54)","(12,55)","(12,56)"}
(14,59)   | 320    | {"(14,59)","(14,60)","(14,61)","(14,62)","(14,63)"}
(167,16)  | 376    | {"(167,16)","(167,17)","(167,18)","(167,19)","(167,20)"}
(170,30)  | 376    | {"(170,30)","(170,31)","(170,32)","(170,33)","(170,34)"}
(173,44)  | 197    | {"(173,44)","(173,45)","(173,46)","(173,47)","(173,48)"}
(7 rows)
```

F.32.6. Hash Functions

`hash_page_type(page bytea)` returns text

`hash_page_type` returns page type of the given HASH index page. For example:

```
test=# SELECT hash_page_type(get_raw_page('con_hash_index', 0));
 hash_page_type
-----
metapage
```

`hash_page_stats(page bytea)` returns setof record

`hash_page_stats` returns information about a bucket or overflow page of a HASH index. For example:

```
test=# SELECT * FROM hash_page_stats(get_raw_page('con_hash_index', 1));
-[ RECORD 1 ]-----+-----
```

```
live_items      | 407
dead_items      | 0
page_size       | 8192
free_size       | 8
hasho_prevblkno | 4096
hasho_nextblkno | 8474
hasho_bucket     | 0
hasho_flag       | 66
hasho_page_id    | 65408
```

hash_page_items(page bytea) returns setof record

hash_page_items returns information about the data stored in a bucket or overflow page of a HASH index page. For example:

```
test=# SELECT * FROM hash_page_items(get_raw_page('con_hash_index', 1)) LIMIT 5;
 itemoffset |   ctid   |   data
-----+-----+-----
          1 | (899,77) | 1053474816
          2 | (897,29) | 1053474816
          3 | (894,207)| 1053474816
          4 | (892,159)| 1053474816
          5 | (890,111)| 1053474816
```

hash_bitmap_info(index oid, blkno int) returns record

hash_bitmap_info shows the status of a bit in the bitmap page for a particular overflow page of HASH index. For example:

```
test=# SELECT * FROM hash_bitmap_info('con_hash_index', 2052);
 bitmapblkno | bitmapbit | bitstatus
-----+-----+-----
          65 |          3 | t
```

hash_metapage_info(page bytea) returns record

hash_metapage_info returns information stored in the meta page of a HASH index. For example:

```
test=# SELECT magic, version, ntuples, ffactor, bsize, bmsize, bmshift,
test-#       maxbucket, highmask, lowmask, ovflpoint, firstfree, nmaps, procid,
test-#       regexp_replace(spares::text, '(.0)*}', '{}') as spares,
test-#       regexp_replace(mapp::text, '(.0)*}', '{}') as mapp
test-# FROM hash_metapage_info(get_raw_page('con_hash_index', 0));
-[ RECORD 1 ]-----
 magic      | 105121344
 version    | 4
 ntuples    | 500500
 ffactor    | 40
 bsize      | 8152
 bmsize     | 4096
 bmshift    | 15
 maxbucket  | 12512
 highmask   | 16383
 lowmask    | 8191
 ovflpoint  | 28
 firstfree  | 1204
 nmaps      | 1
 procid     | 450
 spares     | {0,0,0,0,0,0,1,1,1,1,1,1,1,1,3,4,4,4,45,55,58,59,
 508,567,628,704,1193,1202,1204}
 mapp       | {65}
```

F.33. passwordcheck

The `passwordcheck` module checks users' passwords whenever they are set with `CREATE ROLE` or `ALTER ROLE` (it doesn't work, if a non-default profile is assigned to the user). If a password is considered too weak, it will be rejected and the command will terminate with an error.

To enable this module, add '`$libdir/passwordcheck`' to `shared_preload_libraries` in `postgresql.conf`, then restart the server.

Caution

To prevent unencrypted passwords from being sent across the network, written to the server log or otherwise stolen by a database administrator, Postgres Pro allows the user to supply pre-encrypted passwords. Many client programs make use of this functionality and encrypt the password before sending it to the server.

This limits the usefulness of the `passwordcheck` module, because in that case it can only try to guess the password. For this reason, `passwordcheck` is not recommended if your security requirements are high. It is more secure to use an external authentication method such as GSSAPI (see [Chapter 20](#)) than to rely on passwords within the database.

F.34. pg_buffercache

The `pg_buffercache` module provides a means for examining what's happening in the shared buffer cache in real time.

The module provides a C function `pg_buffercache_pages` that returns a set of records, plus a view `pg_buffercache` that wraps the function for convenient use.

By default, use is restricted to superusers and members of the `pg_monitor` role. Access may be granted to others using `GRANT`.

F.34.1. The pg_buffercache View

The definitions of the columns exposed by the view are shown in [Table F.20](#).

Table F.20. pg_buffercache Columns

Column Type	Description
<code>bufferid integer</code>	ID, in the range 1.. <code>shared_buffers</code>
<code>relfilenode oid (references pg_class .relfilenode)</code>	Filenode number of the relation
<code>reltablespace oid (references pg_tablespace .oid)</code>	Tablespace OID of the relation
<code>reldatabase oid (references pg_database .oid)</code>	Database OID of the relation
<code>relforknumber smallint</code>	Fork number within the relation; see <code>include/common/relpath.h</code>
<code>relblocknumber bigint</code>	Page number within the relation
<code>isdirty boolean</code>	Is the page dirty?

Column Type	Description
usagecount smallint	Clock-sweep access count
pinning_backends integer	Number of backends pinning this buffer

There is one row for each buffer in the shared cache. Unused buffers are shown with all fields null except `bufferid`. Shared system catalogs are shown as belonging to database zero.

Because the cache is shared by all the databases, there will normally be pages from relations not belonging to the current database. This means that there may not be matching join rows in `pg_class` for some rows, or that there could even be incorrect joins. If you are trying to join against `pg_class`, it's a good idea to restrict the join to rows having `reldatabase` equal to the current database's OID or zero.

Since buffer manager locks are not taken to copy the buffer state data that the view will display, accessing `pg_buffercache` view has less impact on normal buffer activity but it doesn't provide a consistent set of results across all buffers. However, we ensure that the information of each buffer is self-consistent.

F.34.2. Sample Output

```
regression=# SELECT n.nspname, c.relname, count(*) AS buffers
              FROM pg_buffercache b JOIN pg_class c
              ON b.relfilenode = pg_relation_filenode(c.oid) AND
                 b.reldatabase IN (0, (SELECT oid FROM pg_database
                                     WHERE datname = current_database()))
              JOIN pg_namespace n ON n.oid = c.relnamespace
              GROUP BY n.nspname, c.relname
              ORDER BY 3 DESC
              LIMIT 10;
```

nspname	relname	buffers
public	delete_test_table	593
public	delete_test_table_pkey	494
pg_catalog	pg_attribute	472
public	quad_poly_tbl	353
public	tenk2	349
public	tenk1	349
public	gin_test_idx	306
pg_catalog	pg_largeobject	206
public	gin_test_tbl	188
public	spgist_text_tbl	182

(10 rows)

F.34.3. Authors

Mark Kirkwood <markir@paradise.net.nz>

Design suggestions: Neil Conway <neilc@samurai.com>

Debugging advice: Tom Lane <tgl@sss.pgh.pa.us>

F.35. pgcrypto

The `pgcrypto` module provides cryptographic functions for Postgres Pro.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.35.1. General Hashing Functions

F.35.1.1. `digest()`

`digest(data text, type text)` returns `bytea`
`digest(data bytea, type text)` returns `bytea`

Computes a binary hash of the given *data*. *type* is the algorithm to use. Standard algorithms are `md5`, `sha1`, `sha224`, `sha256`, `sha384` and `sha512`. If `pgcrypto` was built with OpenSSL, more algorithms are available, as detailed in [Table F.24](#).

If you want the digest as a hexadecimal string, use `encode()` on the result. For example:

```
CREATE OR REPLACE FUNCTION sha1(bytea) returns text AS $$
    SELECT encode(digest($1, 'sha1'), 'hex')
$$ LANGUAGE SQL STRICT IMMUTABLE;
```

F.35.1.2. `hmac()`

`hmac(data text, key text, type text)` returns `bytea`
`hmac(data bytea, key bytea, type text)` returns `bytea`

Calculates hashed MAC for *data* with key *key*. *type* is the same as in `digest()`.

This is similar to `digest()` but the hash can only be recalculated knowing the key. This prevents the scenario of someone altering data and also changing the hash to match.

If the key is larger than the hash block size it will first be hashed and the result will be used as key.

F.35.2. Password Hashing Functions

The functions `crypt()` and `gen_salt()` are specifically designed for hashing passwords. `crypt()` does the hashing and `gen_salt()` prepares algorithm parameters for it.

The algorithms in `crypt()` differ from the usual MD5 or SHA1 hashing algorithms in the following respects:

1. They are slow. As the amount of data is so small, this is the only way to make brute-forcing passwords hard.
2. They use a random value, called the *salt*, so that users having the same password will have different encrypted passwords. This is also an additional defense against reversing the algorithm.
3. They include the algorithm type in the result, so passwords hashed with different algorithms can co-exist.
4. Some of them are adaptive — that means when computers get faster, you can tune the algorithm to be slower, without introducing incompatibility with existing passwords.

[Table F.21](#) lists the algorithms supported by the `crypt()` function.

Table F.21. Supported Algorithms for `crypt()`

Algorithm	Max Password Length	Adaptive?	Salt Bits	Output Length	Description
bf	72	yes	128	60	Blowfish-based, variant 2a
md5	unlimited	no	48	34	MD5-based crypt
xdes	8	yes	24	20	Extended DES
des	8	no	12	13	Original UNIX crypt

F.35.2.1. crypt ()

`crypt(password text, salt text)` returns text

Calculates a `crypt(3)`-style hash of *password*. When storing a new password, you need to use `gen_salt()` to generate a new *salt* value. To check a password, pass the stored hash value as *salt*, and test whether the result matches the stored value.

Example of setting a new password:

```
UPDATE ... SET pswhash = crypt('new password', gen_salt('md5'));
```

Example of authentication:

```
SELECT (pswhash = crypt('entered password', pswhash)) AS pswmatch FROM ... ;
```

This returns `true` if the entered password is correct.

F.35.2.2. gen_salt ()

`gen_salt(type text [, iter_count integer])` returns text

Generates a new random salt string for use in `crypt()`. The salt string also tells `crypt()` which algorithm to use.

The *type* parameter specifies the hashing algorithm. The accepted types are: `des`, `xdes`, `md5` and `bf`.

The *iter_count* parameter lets the user specify the iteration count, for algorithms that have one. The higher the count, the more time it takes to hash the password and therefore the more time to break it. Although with too high a count the time to calculate a hash may be several years — which is somewhat impractical. If the *iter_count* parameter is omitted, the default iteration count is used. Allowed values for *iter_count* depend on the algorithm and are shown in [Table F.22](#).

Table F.22. Iteration Counts for crypt ()

Algorithm	Default	Min	Max
xdes	725	1	16777215
bf	6	4	31

For `xdes` there is an additional limitation that the iteration count must be an odd number.

To pick an appropriate iteration count, consider that the original DES `crypt` was designed to have the speed of 4 hashes per second on the hardware of that time. Slower than 4 hashes per second would probably dampen usability. Faster than 100 hashes per second is probably too fast.

[Table F.23](#) gives an overview of the relative slowness of different hashing algorithms. The table shows how much time it would take to try all combinations of characters in an 8-character password, assuming that the password contains either only lower case letters, or upper- and lower-case letters and numbers. In the `crypt-bf` entries, the number after a slash is the *iter_count* parameter of `gen_salt`.

Table F.23. Hash Algorithm Speeds

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
crypt-bf/8	1792	4 years	3927 years	100k
crypt-bf/7	3648	2 years	1929 years	50k
crypt-bf/6	7168	1 year	982 years	25k
crypt-bf/5	13504	188 days	521 years	12.5k
crypt-md5	171584	15 days	41 years	1k
crypt-des	23221568	157.5 minutes	108 days	7

Algorithm	Hashes/sec	For [a-z]	For [A-Za-z0-9]	Duration relative to md5 hash
sha1	37774272	90 minutes	68 days	4
md5 (hash)	150085504	22.5 minutes	17 days	1

Notes:

- The machine used is an Intel Mobile Core i3.
- `crypt-des` and `crypt-md5` algorithm numbers are taken from John the Ripper v1.6.38 `-test` output.
- `md5 hash` numbers are from `mdcrack 1.2`.
- `sha1` numbers are from `lcrack-20031130-beta`.
- `crypt-bf` numbers are taken using a simple program that loops over 1000 8-character passwords. That way I can show the speed with different numbers of iterations. For reference: `john -test` shows 13506 loops/sec for `crypt-bf/5`. (The very small difference in results is in accordance with the fact that the `crypt-bf` implementation in `pgcrypto` is the same one used in John the Ripper.)

Note that “try all combinations” is not a realistic exercise. Usually password cracking is done with the help of dictionaries, which contain both regular words and various mutations of them. So, even somewhat word-like passwords could be cracked much faster than the above numbers suggest, while a 6-character non-word-like password may escape cracking. Or not.

F.35.3. PGP Encryption Functions

The functions here implement the encryption part of the OpenPGP (RFC 4880) standard. Supported are both symmetric-key and public-key encryption.

An encrypted PGP message consists of 2 parts, or *packets*:

- Packet containing a session key — either symmetric-key or public-key encrypted.
- Packet containing data encrypted with the session key.

When encrypting with a symmetric key (i.e., a password):

1. The given password is hashed using a String2Key (S2K) algorithm. This is rather similar to `crypt()` algorithms — purposefully slow and with random salt — but it produces a full-length binary key.
2. If a separate session key is requested, a new random key will be generated. Otherwise the S2K key will be used directly as the session key.
3. If the S2K key is to be used directly, then only S2K settings will be put into the session key packet. Otherwise the session key will be encrypted with the S2K key and put into the session key packet.

When encrypting with a public key:

1. A new random session key is generated.
2. It is encrypted using the public key and put into the session key packet.

In either case the data to be encrypted is processed as follows:

1. Optional data-manipulation: compression, conversion to UTF-8, and/or conversion of line-endings.
2. The data is prefixed with a block of random bytes. This is equivalent to using a random IV.
3. An SHA1 hash of the random prefix and data is appended.
4. All this is encrypted with the session key and placed in the data packet.

F.35.3.1. `pgp_sym_encrypt()`

`pgp_sym_encrypt(data text, psw text [, options text])` returns `bytea`

`pgp_sym_encrypt_bytea(data bytea, psw text [, options text ])` returns `bytea`

Encrypt *data* with a symmetric PGP key *psw*. The *options* parameter can contain option settings, as described below.

F.35.3.2. `pgp_sym_decrypt()`

`pgp_sym_decrypt(msg bytea, psw text [, options text ])` returns `text`

`pgp_sym_decrypt_bytea(msg bytea, psw text [, options text ])` returns `bytea`

Decrypt a symmetric-key-encrypted PGP message.

Decrypting `bytea` data with `pgp_sym_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_sym_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.35.3.3. `pgp_pub_encrypt()`

`pgp_pub_encrypt(data text, key bytea [, options text ])` returns `bytea`

`pgp_pub_encrypt_bytea(data bytea, key bytea [, options text ])` returns `bytea`

Encrypt *data* with a public PGP key *key*. Giving this function a secret key will produce an error.

The *options* parameter can contain option settings, as described below.

F.35.3.4. `pgp_pub_decrypt()`

`pgp_pub_decrypt(msg bytea, key bytea [, psw text [, options text ]])` returns `text`

`pgp_pub_decrypt_bytea(msg bytea, key bytea [, psw text [, options text ]])` returns `bytea`

Decrypt a public-key-encrypted message. *key* must be the secret key corresponding to the public key that was used to encrypt. If the secret key is password-protected, you must give the password in *psw*. If there is no password, but you want to specify options, you need to give an empty password.

Decrypting `bytea` data with `pgp_pub_decrypt` is disallowed. This is to avoid outputting invalid character data. Decrypting originally textual data with `pgp_pub_decrypt_bytea` is fine.

The *options* parameter can contain option settings, as described below.

F.35.3.5. `pgp_key_id()`

`pgp_key_id(bytea)` returns `text`

`pgp_key_id` extracts the key ID of a PGP public or secret key. Or it gives the key ID that was used for encrypting the data, if given an encrypted message.

It can return 2 special key IDs:

- `SYMKEY`

The message is encrypted with a symmetric key.

- `ANYKEY`

The message is public-key encrypted, but the key ID has been removed. That means you will need to try all your secret keys on it to see which one decrypts it. `pgcrypto` itself does not produce such messages.

Note that different keys may have the same ID. This is rare but a normal event. The client application should then try to decrypt with each one, to see which fits — like handling `ANYKEY`.

F.35.3.6. `armor()`, `dearmor()`

`armor(data bytea [ , keys text[], values text[] ]) returns text`
`dearmor(data text) returns bytea`

These functions wrap/unwrap binary data into PGP ASCII-armor format, which is basically Base64 with CRC and additional formatting.

If the *keys* and *values* arrays are specified, an *armor header* is added to the armored format for each key/value pair. Both arrays must be single-dimensional, and they must be of the same length. The keys and values cannot contain any non-ASCII characters.

F.35.3.7. pgp_armor_headers

`pgp_armor_headers(data text, key out text, value out text) returns setof record`

`pgp_armor_headers()` extracts the armor headers from *data*. The return value is a set of rows with two columns, key and value. If the keys or values contain any non-ASCII characters, they are treated as UTF-8.

F.35.3.8. Options for PGP Functions

Options are named to be similar to GnuPG. An option's value should be given after an equal sign; separate options from each other with commas. For example:

`pgp_sym_encrypt(data, psw, 'compress-algo=1, cipher-algo=aes256')`

All of the options except `convert-crlf` apply only to encrypt functions. Decrypt functions get the parameters from the PGP data.

The most interesting options are probably `compress-algo` and `unicode-mode`. The rest should have reasonable defaults.

F.35.3.8.1. cipher-algo

Which cipher algorithm to use.

Values: bf, aes128, aes192, aes256 (OpenSSL-only: 3des, cast5)

Default: aes128

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.35.3.8.2. compress-algo

Which compression algorithm to use. Only available if Postgres Pro was built with zlib.

Values:

0 - no compression

1 - ZIP compression

2 - ZLIB compression (= ZIP plus meta-data and block CRCs)

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.35.3.8.3. compress-level

How much to compress. Higher levels compress smaller but are slower. 0 disables compression.

Values: 0, 1-9

Default: 6

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.35.3.8.4. convert-crlf

Whether to convert `\n` into `\r\n` when encrypting and `\r\n` to `\n` when decrypting. RFC 4880 specifies that text data should be stored using `\r\n` line-feeds. Use this to get fully RFC-compliant behavior.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`, `pgp_sym_decrypt`, `pgp_pub_decrypt`

F.35.3.8.5. disable-mdc

Do not protect data with SHA-1. The only good reason to use this option is to achieve compatibility with ancient PGP products, predating the addition of SHA-1 protected packets to RFC 4880. Recent gnupg.org and pgp.com software supports it fine.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.35.3.8.6. sess-key

Use separate session key. Public-key encryption always uses a separate session key; this option is for symmetric-key encryption, which by default uses the S2K key directly.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`

F.35.3.8.7. s2k-mode

Which S2K algorithm to use.

Values:

0 - Without salt. Dangerous!

1 - With salt but with fixed iteration count.

3 - Variable iteration count.

Default: 3

Applies to: `pgp_sym_encrypt`

F.35.3.8.8. s2k-count

The number of iterations of the S2K algorithm to use. It must be a value between 1024 and 65011712, inclusive.

Default: A random value between 65536 and 253952

Applies to: `pgp_sym_encrypt`, only with `s2k-mode=3`

F.35.3.8.9. s2k-digest-algo

Which digest algorithm to use in S2K calculation.

Values: `md5`, `sha1`

Default: `sha1`

Applies to: `pgp_sym_encrypt`

F.35.3.8.10. s2k-cipher-algo

Which cipher to use for encrypting separate session key.

Values: `bf`, `aes`, `aes128`, `aes192`, `aes256`

Default: `use cipher-algo`

Applies to: `pgp_sym_encrypt`

F.35.3.8.11. unicode-mode

Whether to convert textual data from database internal encoding to UTF-8 and back. If your database already is UTF-8, no conversion will be done, but the message will be tagged as UTF-8. Without this option it will not be.

Values: 0, 1

Default: 0

Applies to: `pgp_sym_encrypt`, `pgp_pub_encrypt`

F.35.3.9. Generating PGP Keys with GnuPG

To generate a new key:

```
gpg --gen-key
```

The preferred key type is “DSA and Elgamal”.

For RSA encryption you must create either DSA or RSA sign-only key as master and then add an RSA encryption subkey with `gpg --edit-key`.

To list keys:

```
gpg --list-secret-keys
```

To export a public key in ASCII-armor format:

```
gpg -a --export KEYID > public.key
```

To export a secret key in ASCII-armor format:

```
gpg -a --export-secret-keys KEYID > secret.key
```

You need to use `dearmor()` on these keys before giving them to the PGP functions. Or if you can handle binary data, you can drop `-a` from the command.

For more details see `man gpg`, *The GNU Privacy Handbook* and other documentation on <https://www.gnupg.org/>.

F.35.3.10. Limitations of PGP Code

- No support for signing. That also means that it is not checked whether the encryption subkey belongs to the master key.
- No support for encryption key as master key. As such practice is generally discouraged, this should not be a problem.
- No support for several subkeys. This may seem like a problem, as this is common practice. On the other hand, you should not use your regular GPG/PGP keys with `pgcrypto`, but create new ones, as the usage scenario is rather different.

F.35.4. Raw Encryption Functions

These functions only run a cipher over data; they don't have any advanced features of PGP encryption. Therefore they have some major problems:

1. They use user key directly as cipher key.
2. They don't provide any integrity checking, to see if the encrypted data was modified.
3. They expect that users manage all encryption parameters themselves, even IV.
4. They don't handle text.

So, with the introduction of PGP encryption, usage of raw encryption functions is discouraged.

```
encrypt(data bytea, key bytea, type text) returns bytea
```

```
decrypt(data bytea, key bytea, type text) returns bytea
```

```
encrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

```
decrypt_iv(data bytea, key bytea, iv bytea, type text) returns bytea
```

Encrypt/decrypt data using the cipher method specified by *type*. The syntax of the *type* string is:

```
algorithm [ - mode ] [ /pad: padding ]
```

where *algorithm* is one of:

- *bf* — Blowfish
- *aes* — AES (Rijndael-128, -192 or -256)

and *mode* is one of:

- *cbc* — next block depends on previous (default)
- *ecb* — each block is encrypted separately (for testing only)

and *padding* is one of:

- *pkcs* — data may be any length (default)
- *none* — data must be multiple of cipher block size

So, for example, these are equivalent:

```
encrypt(data, 'fooz', 'bf')
encrypt(data, 'fooz', 'bf-cbc/pad:pkcs')
```

In `encrypt_iv` and `decrypt_iv`, the *iv* parameter is the initial value for the CBC mode; it is ignored for ECB. It is clipped or padded with zeroes if not exactly block size. It defaults to all zeroes in the functions without this parameter.

F.35.5. Random-Data Functions

`gen_random_bytes(count integer)` returns *bytea*

Returns *count* cryptographically strong random bytes. At most 1024 bytes can be extracted at a time. This is to avoid draining the randomness generator pool.

`gen_random_uuid()` returns *uuid*

Returns a version 4 (random) UUID. (Obsolete, this function internally calls the [core function](#) of the same name.)

F.35.6. Notes

F.35.6.1. Configuration

`pgcrypto` configures itself according to the findings of the main Postgres Pro `configure` script. The options that affect it are `--with-zlib` and `--with-openssl`.

When compiled with `zlib`, PGP encryption functions are able to compress data before encrypting.

When compiled with `OpenSSL`, there will be more algorithms available. Also public-key encryption functions will be faster as `OpenSSL` has more optimized `BIGNUM` functions.

Table F.24. Summary of Functionality with and without OpenSSL

Functionality	Built-in	With OpenSSL
MD5	yes	yes
SHA1	yes	yes
SHA224/256/384/512	yes	yes
Other digest algorithms	no	yes (Note 1)
Blowfish	yes	yes

Functionality	Built-in	With OpenSSL
AES	yes	yes
DES/3DES/CAST5	no	yes
Raw encryption	yes	yes
PGP Symmetric encryption	yes	yes
PGP Public-Key encryption	yes	yes

When compiled against OpenSSL 3.0.0 and later versions, the legacy provider must be activated in the `openssl.cnf` configuration file in order to use older ciphers like DES or Blowfish.

Notes:

1. Any digest algorithm OpenSSL supports is automatically picked up. This is not possible with ciphers, which need to be supported explicitly.

F.35.6.2. NULL Handling

As is standard in SQL, all functions return NULL, if any of the arguments are NULL. This may create security risks on careless usage.

F.35.6.3. Security Limitations

All `pgcrypto` functions run inside the database server. That means that all the data and passwords move between `pgcrypto` and client applications in clear text. Thus you must:

1. Connect locally or use SSL connections.
2. Trust both system and database administrator.

If you cannot, then better do crypto inside client application.

The implementation does not resist [side-channel attacks](#). For example, the time required for a `pgcrypto` decryption function to complete varies among ciphertexts of a given size.

F.35.7. Author

Marko Kreen <markokr@gmail.com>

`pgcrypto` uses code from the following sources:

Algorithm	Author	Source origin
DES crypt	David Burren and others	FreeBSD libcrypt
MD5 crypt	Poul-Henning Kamp	FreeBSD libcrypt
Blowfish crypt	Solar Designer	www.openwall.com
Blowfish cipher	Simon Tatham	PuTTY
Rijndael cipher	Brian Gladman	OpenBSD sys/crypto
MD5 hash and SHA1	WIDE Project	KAME kame/sys/crypto
SHA256/384/512	Aaron D. Gifford	OpenBSD sys/crypto
BIGNUM math	Michael J. Fromberger	dartmouth.edu/~sting/sw/imath

F.36. pg_freespacemap

The `pg_freespacemap` module provides a means for examining the free space map (FSM). It provides a function called `pg_freespace`, or two overloaded functions, to be precise. The functions show the value recorded in the free space map for a given page, or for all pages in the relation.

By default use is restricted to superusers and members of the `pg_stat_scan_tables` role. Access may be granted to others using `GRANT`.

F.36.1. Functions

`pg_freespace(rel regclass IN, blkno bigint IN)` returns `int2`

Returns the amount of free space on the page of the relation, specified by `blkno`, according to the FSM.

`pg_freespace(rel regclass IN, blkno OUT bigint, avail OUT int2)`

Displays the amount of free space on each page of the relation, according to the FSM. A set of (`blkno bigint`, `avail int2`) tuples is returned, one tuple for each page in the relation.

The values stored in the free space map are not exact. They're rounded to precision of 1/256th of `BLCKSZ` (32 bytes with default `BLCKSZ`), and they're not kept fully up-to-date as tuples are inserted and updated.

For indexes, what is tracked is entirely-unused pages, rather than free space within pages. Therefore, the values are not meaningful, just whether a page is full or empty.

Note

The interface was changed in version 8.4, to reflect the new FSM implementation introduced in the same version.

F.36.2. Sample Output

```
postgres=# SELECT * FROM pg_freespace('foo');
```

blkno	avail
0	0
1	0
2	0
3	32
4	704
5	704
6	704
7	1216
8	704
9	704
10	704
11	704
12	704
13	704
14	704
15	704
16	704

F.36.3. Author

Original version by Mark Kirkwood <markir@paradise.net.nz>. Rewritten in version 8.4 to suit new FSM implementation by Heikki Linnakangas <heikki@enterprisedb.com>

F.37. pg_hint_plan

F.37.1. Name

`pg_hint_plan` is a module that allows a user to control an execution plan with hinting phrases mentioned in comments of a special form.

F.37.2. Synopsis

Postgres Pro Enterprise uses a cost-based optimizer, which utilizes data statistics rather than static rules. The planner (optimizer) estimates costs of all possible execution plans for an SQL statement, then the execution plan with the lowest cost is executed. The planner makes every effort to select the best, but not perfect, execution plan since it does not count some properties of the data, for example, correlation between columns.

`pg_hint_plan` makes it possible to tweak execution plans using so-called “hints”, which are simple descriptions added in SQL comments of a special form.

F.37.3. Description

F.37.3.1. Basic Usage

`pg_hint_plan` reads hinting phrases in comments of a special form given with the target SQL statement. The special comment begins with the character sequence `/*+` and ends with `*/`. Hinting phrases consist of a hint name and following parameters enclosed in parentheses and delimited by spaces. Each hinting phrase can be delimited by new lines for readability.

In the example below, a hash join is selected as a joining method and `pgbench_accounts` is scanned by a sequential scan method.

```
postgres=# /*+
postgres*#      HashJoin(a b)
postgres*#      SeqScan(a)
postgres*#      */
postgres-# EXPLAIN SELECT *
postgres-#      FROM pgbench_branches b
postgres-#      JOIN pgbench_accounts a ON b.bid = a.bid
postgres-#      ORDER BY a.aid;

                                QUERY PLAN
-----
Sort  (cost=31465.84..31715.84 rows=100000 width=197)
  Sort Key: a.aid
    -> Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
      Hash Cond: (a.bid = b.bid)
        -> Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)
        -> Hash  (cost=1.01..1.01 rows=1 width=100)
          -> Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)
(7 rows)

postgres=#
```

F.37.4. Hint Table

The above section mentions that hints are inserted in a comment of a special form. This is inconvenient if a query cannot be edited. For such cases, hints can be placed in a special table called `hint_plan.hints`, which looks as follows:

Column	Description
id	A unique number to identify a row for a hint. This column is filled automatically by sequence.
norm_query_string	A pattern that matches the query to be hinted. Constants in the query should be replaced with ? as in the example below. Whitespaces are significant in the pattern.
application_name	A value of <i>application_name</i> of sessions to apply the hint to. The hint in the example below applies to sessions connected from psql. An empty string means sessions with any <i>application_name</i> .
hint	A hint phrase. This must be a series of hints excluding surrounding comment marks.

The following example shows how to work with the hint table.

```
postgres=# INSERT INTO hint_plan.hints(norm_query_string, application_name, hints)
postgres-#         VALUES (
postgres-#             'EXPLAIN (COSTS false) SELECT * FROM t1 WHERE t1.id = ?;',
postgres-#             'psql',
postgres-#             'SeqScan(t1) '
postgres-#         );
INSERT 0 1
postgres=# UPDATE hint_plan.hints
postgres-#     SET hints = 'IndexScan(t1) '
postgres-# WHERE id = 1;
UPDATE 1
postgres=# DELETE FROM hint_plan.hints
postgres-# WHERE id = 1;
DELETE 1
postgres=#
```

The hint table is owned by the creator user and has the default privileges at the time of creation, i.e. during `CREATE EXTENSION`. Table hints take priority over comment hints.

F.37.4.1. Types of Hints

Hinting phrases are classified into six types based on the kind of object and how they can affect planning: scanning methods, join methods, joining order, row number correction, parallel query, and GUC setting. You will see the lists of hinting phrases of each type in the Hint List (See [Section F.37.10](#)).

F.37.4.1.1. Hints for Scan Methods

Scan method hints enforce a specific scanning method on the target table. `pg_hint_plan` recognizes the target table by alias names, if any. In this kind of hint, they are `SeqScan`, `IndexScan`, and so on.

Scan hints are effective on ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables and system catalogs. External (foreign) tables, table functions, `VALUES` clause, CTEs, views and subqueries are not affected.

```
postgres=# /*+
postgres*#     SeqScan(t1)
postgres*#     IndexScan(t2 t2_pkey)
postgres*# */
postgres-# SELECT * FROM table1 t1 JOIN table2 t2 ON (t1.key = t2.key);
```

F.37.4.1.2. Hints for Join Methods

Join method hints enforce join methods of the joins involving the specified tables.

This can affect joins only on ordinary tables, inheritance tables, `UNLOGGED` tables, temporary tables, external (foreign) tables, system catalogs, table functions, `VALUES` command results, and CTEs. But joins on views and subqueries are not affected.

Join method hints are recommended to be used together with the `Leading` joining order hint because it guarantees that a joining order specified in the request will be executed.

The hint below prompts the `NestLoop(MergeJoin(c b) a)` joining structure:

```
postgres=# /*+ Leading(((c b) a)) MergeJoin(c b) NestLoop(a b c) */ EXPLAIN(COSTS OFF,
TIMING OFF, SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c WHERE a.f1 = b.f1 AND b.f1 = c.f1;
```

QUERY PLAN

```
-----
Aggregate
->  Nested Loop
      ->  Merge Join
            Merge Cond: (c.f1 = b.f1)
            ->  Index Only Scan using t1_idx1 on t1 c
            ->  Materialize
                  ->  Index Only Scan using t1_idx1 on t1 b
      ->  Memoize
            Cache Key: b.f1
            Cache Mode: logical
            ->  Index Only Scan using t1_idx1 on t1 a
                  Index Cond: (f1 = b.f1)
```

F.37.4.1.3. Hint for Joining Order

The `Leading` hint enforces the joining order for two or more tables. There are two ways of enforcing. One is enforcing specific joining order but not restricting direction at each join level:

```
postgres=# /*+
postgres*#      NestLoop(t1 t2)
postgres*#      MergeJoin(t1 t2 t3)
postgres*#      Leading(t1 t2 t3)
postgres*#      */
postgres-# SELECT * FROM table1 t1
postgres-#      JOIN table table2 t2 ON (t1.key = t2.key)
postgres-#      JOIN table table3 t3 ON (t2.key = t3.key);
```

Another way also enforces join direction. When the above join order is specified, the join direction chosen by the planner (outer table — inner table) may be different from the expected one. If you want to change the join direction in such a situation, use the following format:

```
postgres=# / * + Leading ((t1 (t2 t3))) * / SELECT ...
```

In this format, two elements enclosed in parentheses are nested, and within one parenthesis, the first element is the outer table, and the second element is the inner table.

Note that the `Leading` hint (just like join methods) does not operate together with [GEQO](#) if the number of tables specified in the request exceeds `geqo_threshold`.

Some extra examples of using the hint for joining order:

```
postgres=# /*+ Leading(((c b) a)) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c WHERE a.f1 = b.f1 AND b.f1 = c.f1;
QUERY PLAN
```

```
Aggregate
-> Hash Join
    Hash Cond: (b.f1 = a.f1)
    -> Nested Loop
        -> Index Only Scan using t1_idx1 on t1 c
        -> Memoize
            Cache Key: c.f1
            Cache Mode: logical
            -> Index Only Scan using t1_idx1 on t1 b
                Index Cond: (f1 = c.f1)
    -> Hash
        -> Seq Scan on t1 a
```

And an example below:

```
postgres=# /*+ Leading(((d c) (b a))) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT count(*) FROM t1 a, t1 b, t1 c, t1 d WHERE a.f1 = b.f1 AND b.f1 = c.f1 AND c.f1
= d.f1;
```

QUERY PLAN

```
-----
Aggregate
-> Hash Join
    Hash Cond: (c.f1 = a.f1)
    -> Nested Loop
        -> Index Only Scan using t1_idx1 on t1 d
        -> Memoize
            Cache Key: d.f1
            Cache Mode: logical
            -> Index Only Scan using t1_idx1 on t1 c
                Index Cond: (f1 = d.f1)
    -> Hash
        -> Hash Join
            Hash Cond: (b.f1 = a.f1)
            -> Seq Scan on t1 b
            -> Hash
                -> Seq Scan on t1 a
```

For details, see [Section F.37.10](#).

F.37.4.1.4. Hint for Row Number Correction

The `Rows` hint corrects row number misestimation of joins that comes from restrictions of the planner.

```
postgres=# /*+ Rows(a b #10) */ SELECT... ; Sets rows of join result to 10
postgres=# /*+ Rows(a b +10) */ SELECT... ; Increments row number by 10
postgres=# /*+ Rows(a b -10) */ SELECT... ; Subtracts 10 from the row number.
postgres=# /*+ Rows(a b *10) */ SELECT... ; Makes the number 10 times larger.
```

F.37.4.1.5. Hint for Parallel Plan

The `Parallel` hint enforces parallel execution configuration on scans. The third parameter specifies the strength of enforcement. “soft” means that `pg_hint_plan` only changes `max_parallel_workers_per_gather` and leaves all others to the planner. “hard” changes other planner parameters so as to forcibly apply the number. This can affect ordinary tables, inheritance parents, `UNLOGGED` tables and system catalog. External tables, table functions, `VALUES` clause, CTEs, views and subqueries are not affected. Internal tables of a view can be specified by its real name/alias as the target object. The following example shows that the query is enforced differently on each table.

```
postgres=# explain /*+ Parallel(c1 3 hard) Parallel(c2 5 hard) */
```

```
SELECT c2.a FROM c1 JOIN c2 ON (c1.a = c2.a);
QUERY PLAN
```

```
-----
Hash Join  (cost=2.86..11406.38 rows=101 width=4)
  Hash Cond: (c1.a = c2.a)
    -> Gather  (cost=0.00..7652.13 rows=1000101 width=4)
        Workers Planned: 3
        -> Parallel Seq Scan on c1  (cost=0.00..7652.13 rows=322613 width=4)
    -> Hash  (cost=1.59..1.59 rows=101 width=4)
        -> Gather  (cost=0.00..1.59 rows=101 width=4)
            Workers Planned: 5
            -> Parallel Seq Scan on c2  (cost=0.00..1.59 rows=59 width=4)
```

```
postgres=# EXPLAIN /*+ Parallel(t1 5 hard) */ SELECT sum(a) FROM t1;
QUERY PLAN
```

```
-----
Finalize Aggregate  (cost=693.02..693.03 rows=1 width=8)
  -> Gather  (cost=693.00..693.01 rows=5 width=8)
      Workers Planned: 5
      -> Partial Aggregate  (cost=693.00..693.01 rows=1 width=8)
          -> Parallel Seq Scan on t1  (cost=0.00..643.00 rows=20000 width=4)
```

F.37.4.1.6. Hints for Stored Procedures

Hints can be used with stored procedures. Be careful when using hints, since they can be inherited.

```
postgres=# CREATE OR REPLACE FUNCTION test_1() RETURNS bool AS $$
BEGIN
EXECUTE 'SELECT count(*) FROM t1 WHERE f1 < 2' ;
RETURN true;
END; $$ language plpgsql;
```

```
postgres=# CREATE OR REPLACE FUNCTION test_2() RETURNS void AS $$
BEGIN
EXECUTE 'SELECT /*+ SET(enable_bitmapscan off)*/ test_1()' ;
END;
$$ language plpgsql;
```

```
postgres=# SELECT test_2();
```

```
Query Text: SELECT count(*) FROM t1 WHERE f1 < 2
Aggregate  (cost=18.00..18.01 rows=1 width=8) (actual time=0.511..0.512 rows=1
loops=1)
  -> Seq Scan on t1  (cost=0.00..17.50 rows=200 width=0) (actual time=0.105..0.457
rows=200 loops=1)
    Filter: (f1 < 2)
    Rows Removed by Filter: 800
```

F.37.4.1.7. Hints for Prepared Statements

The `pg_hint_plan` extension allows using hints with prepared statements. Hints should be specified in the `PREPARE` statement and are ignored in the `EXECUTE` statement.

Below are a couple of sample queries. With the `IndexOnlyScan(t1)` hint:

```
postgres=# /*+ IndexOnlyScan(t1) */ PREPARE stmt AS SELECT count(*) FROM t1 WHERE f1 <
2;

EXPLAIN EXECUTE stmt;
EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF) EXECUTE stmt;
```

QUERY PLAN

Aggregate-> Index Only Scan using t1_idx1 on t1
Index Cond: (f1 < 2)And with the `BitmapScan(t1)` hint:

```
postgres=# /*+ BitmapScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF) EXECUTE
stmt;
```

QUERY PLAN

Aggregate-> Index Only Scan using t1_idx1 on t1
Index Cond: (f1 < 2)**F.37.4.1.8. GUC Parameters Temporarily Setting**

The `Set` hint changes GUC parameters only for the time of planning. GUC parameter shown in [Section 19.7.2](#) can have the expected effects on planning unless any other hint conflicts with the planner method configuration parameters. The last one among hints on the same GUC parameter takes effect. GUC parameters for `pg_hint_plan` are also settable by this hint, but it will not work as you expect.

```
postgres=# /*+ Set(random_page_cost 2.0) */
postgres=# SELECT * FROM table1 t1 WHERE key = 'value';
...
```

F.37.4.2. GUC Parameters for `pg_hint_plan`

GUC parameters described below affect the behavior of `pg_hint_plan`.

Table F.25. GUC Parameters

Parameter Name	Description	Default Value
<code>pg_hint_plan.enable_hint</code>	True enables <code>pg_hint_plan</code> .	on
<code>pg_hint_plan.enable_hint_table</code>	True enables hinting by table.	on
<code>pg_hint_plan.parse_messages</code>	Specifies the log level of hint parse error. Valid values are <code>error</code> , <code>warning</code> , <code>notice</code> , <code>info</code> , <code>log</code> , <code>debug</code> .	INFO
<code>pg_hint_plan.debug_print</code>	Controls debug print and verbosity. Valid values are <code>off</code> , <code>on</code> , <code>detailed</code> , and <code>verbose</code> .	off
<code>pg_hint_plan.message_level</code>	Specifies message level of debug print. Valid values are <code>error</code> , <code>warning</code> , <code>notice</code> , <code>info</code> , <code>log</code> , <code>debug</code> .	LOG
<code>pg_hint_plan.hints_anywhere</code>	If it is <code>on</code> , <code>pg_hint_plan</code> reads hints ignoring SQL syntax. This allows placing hints anywhere in the query but may cause false reads.	off

F.37.5. Installation

The `pg_hint_plan` extension is provided together with Postgres Pro Enterprise as a separate pre-built package. For detailed package installation instructions, see [Chapter 17](#). Once you have Postgres Pro Enterprise installed, activate `pg_hint_plan`:

```
postgres=# LOAD 'pg_hint_plan';
LOAD
postgres=#
```

You can also load it globally by adding `pg_hint_plan` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file.

```
shared_preload_libraries = 'pg_hint_plan'
```

For automatic loading for specific sessions, use `ALTER USER SET/ALTER DATABASE SET`.

Basically, `pg_hint_plan` does not require `CREATE EXTENSION`, but if you plan to use the hint table, create the extension and enable the `enable_hint_table` parameter:

```
CREATE EXTENSION pg_hint_plan;
SET pg_hint_plan.enable_hint_table TO on;
```

F.37.6. Details in Hinting

F.37.6.1. Syntax and Placement

`pg_hint_plan` reads hints only from the first block comment, and parsing of any characters except letters, digits, spaces, underscores, commas and parentheses is stopped immediately. In the following example `HashJoin(a b)` and `SeqScan(a)` are parsed as hints, but `IndexScan(a)` and `MergeJoin(a b)` are not.

```
postgres=# /*+
postgres*#      HashJoin(a b)
postgres*#      SeqScan(a)
postgres*#      */
postgres-# /*+ IndexScan(a) */
postgres-# EXPLAIN SELECT /*+ MergeJoin(a b) */ *
postgres-#      FROM pgbench_branches b
postgres-#      JOIN pgbench_accounts a ON b.bid = a.bid
postgres-#      ORDER BY a.aid;
```

QUERY PLAN

```
-----
Sort  (cost=31465.84..31715.84 rows=100000 width=197)
  Sort Key: a.aid
    -> Hash Join  (cost=1.02..4016.02 rows=100000 width=197)
          Hash Cond: (a.bid = b.bid)
            -> Seq Scan on pgbench_accounts a  (cost=0.00..2640.00 rows=100000 width=97)
            -> Hash  (cost=1.01..1.01 rows=1 width=100)
                  -> Seq Scan on pgbench_branches b  (cost=0.00..1.01 rows=1 width=100)
(7 rows)
```

```
postgres=#
```

However, when the `hints_anywhere` parameter is on, `pg_hint_plan` reads hints from anywhere in the query so the following hint uses would be equivalent:

```
EXPLAIN /*+ SeqScan(t1) */
SELECT * FROM table1 t1 WHERE a < 10;
```

QUERY PLAN

```
-----
Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)
  Filter: (a < 10)
(2 rows)
```

```
EXPLAIN
```

```
SELECT * FROM table1 t1 WHERE a < 10 AND '/*+SeqScan(t1)*/' <> '';
                                QUERY PLAN
```

```
-----
Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)
  Filter: (a < 10)
(2 rows)
```

```
EXPLAIN
SELECT * FROM table1 t1 WHERE a < 10 /*+SeqScan(t1)*/;
                                QUERY PLAN
```

```
-----
Seq Scan on table1 t1  (cost=0.00..17.50 rows=9 width=8)
  Filter: (a < 10)
(2 rows)
```

F.37.6.2. Using with PL/pgSQL

`pg_hint_plan` works for queries in PL/pgSQL scripts with some restrictions.

- Hints affect only the following kinds of queries:
 - Queries that return one row (`SELECT`, `INSERT`, `UPDATE`, and `DELETE`)
 - Queries that return multiple rows (`RETURN QUERY`)
 - Dynamic SQL statements (`EXECUTE`)
 - Cursor open (`OPEN`)
 - Loop over result of a query (`FOR`)
- A hint comment should be placed after the first word in a query as in the example below, since preceding comments are not sent as a part of the query.

```
postgres=# CREATE FUNCTION hints_func(integer) RETURNS integer AS $$
postgres$# DECLARE
postgres$#     id integer;
postgres$#     cnt integer;
postgres$# BEGIN
postgres$#     SELECT /*+ NoIndexScan(a) */ aid
postgres$#         INTO id FROM pgbench_accounts a WHERE aid = $1;
postgres$#     SELECT /*+ SeqScan(a) */ count(*)
postgres$#         INTO cnt FROM pgbench_accounts a;
postgres$#     RETURN id + cnt;
postgres$# END;
postgres$# $$ LANGUAGE plpgsql;
```

F.37.6.3. Letter Case in Object Names

Unlike the way PostgreSQL handles object names, `pg_hint_plan` compares bare object names in hints against the database internal object names in a case-sensitive way. Therefore, an object name `TBL` in a hint matches only `"TBL"` in database and does not match any unquoted names like `TBL`, `tbl`, or `Tbl`.

F.37.6.4. Escaping Special Characters in Object Names

The objects as the hint parameter should be enclosed in double quotes if they include parentheses, double quotes, and whitespaces. The escaping rule is the same as in PostgreSQL.

F.37.6.5. Distinction Between Multiple Occurrences of a Table

`pg_hint_plan` identifies the target object by using aliases if they exist. This behavior is usable to point at a specific occurrence among multiple occurrences of one table.

```
postgres=# /*+ HashJoin(t1 t1) */
postgres=# EXPLAIN SELECT * FROM s1.t1
postgres=# JOIN public.t1 ON (s1.t1.id=public.t1.id);
INFO:  hint syntax error at or near "HashJoin(t1 t1)"
DETAIL:  Relation name "t1" is ambiguous.
...
postgres=# /*+ HashJoin(pt st) */
postgres=# EXPLAIN SELECT * FROM s1.t1 st
postgres=# JOIN public.t1 pt ON (st.id=pt.id);
               QUERY PLAN
-----
Hash Join  (cost=64.00..1112.00 rows=28800 width=8)
  Hash Cond: (st.id = pt.id)
    -> Seq Scan on t1 st  (cost=0.00..34.00 rows=2400 width=4)
    -> Hash  (cost=34.00..34.00 rows=2400 width=4)
        -> Seq Scan on t1 pt  (cost=0.00..34.00 rows=2400 width=4)
```

F.37.6.6. Underlying Tables of Views or Rules

Hints are not applicable on views themselves, but they can affect the queries within if the object names match the object names in the expanded query on the view. Assigning aliases to the tables in a view enables them to be manipulated from outside of the view.

```
postgres=# CREATE VIEW v1 AS SELECT * FROM t2;
postgres=# EXPLAIN /*+ HashJoin(t1 v1) */
           SELECT * FROM t1 JOIN v1 ON (c1.a = v1.a);
               QUERY PLAN
-----
Hash Join  (cost=3.27..18181.67 rows=101 width=8)
  Hash Cond: (t1.a = t2.a)
    -> Seq Scan on t1  (cost=0.00..14427.01 rows=1000101 width=4)
    -> Hash  (cost=2.01..2.01 rows=101 width=4)
        -> Seq Scan on t2  (cost=0.00..2.01 rows=101 width=4)
```

And one more example:

```
postgres=# CREATE VIEW v1 AS SELECT count(*) FROM t1 WHERE f1 < 2;
/*+ IndexOnlyScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT * FROM v1;
               QUERY PLAN
-----
Aggregate
 -> Index Only Scan using t1_idx1 on t1
     Index Cond: (f1 < 2)
```

Be careful not to select tables with identical names in different views because these tables may become affected. To avoid this, try using unique aliases, for example, a combination of a view name and a table name:

```
postgres=# /*+ SeqScan(t1) */ EXPLAIN (COSTS OFF, TIMING OFF, SUMMARY OFF)
SELECT * FROM v2;
               QUERY PLAN
-----
Nested Loop Semi Join
  Join Filter: ((count(*)) = t1.f1)
    -> Aggregate
        -> Seq Scan on t1 t1_1
            Filter: (f1 < 2)
    -> Seq Scan on t1
```

F.37.6.7. Inheritance Tables

Hints can point only at the parent of inheritance tables, yet they affect all the inheritance. Hints pointing directly at children will not take effect.

F.37.6.8. Hinting on Multistatements

One multistatement can have exactly one hint comment and this hint affects all individual statements in the multistatement. Note that what looks as a multistatement in the psql interactive interface is internally a sequence of single statements, so hints affect only the first statement that follows.

F.37.6.9. VALUES Expressions

VALUES expressions in the FROM clause are named as `*VALUES*` internally, so they are hintable if it is the only VALUES expression in a query. Two or more VALUES expressions in a query may look different in the EXPLAIN response. But in reality it is just a cosmetic improvement and they cannot not be distinguished.

```
postgres=# /*+ MergeJoin(*VALUES*_1 *VALUES*) */
EXPLAIN SELECT * FROM (VALUES (1, 1), (2, 2)) v (a, b)
JOIN (VALUES (1, 5), (2, 8), (3, 4)) w (a, c) ON v.a = w.a;
INFO:  pg_hint_plan: hint syntax error at or near "MergeJoin(*VALUES*_1 *VALUES*)"
DETAIL:  Relation name "*VALUES*" is ambiguous.
        QUERY PLAN

-----
Hash Join  (cost=0.05..0.12 rows=2 width=16)
  Hash Cond: ("*VALUES*_1".column1 = "*VALUES*".column1)
    -> Values Scan on "*VALUES*_1"  (cost=0.00..0.04 rows=3 width=8)
    -> Hash  (cost=0.03..0.03 rows=2 width=8)
        -> Values Scan on "*VALUES*"  (cost=0.00..0.03 rows=2 width=8)
```

F.37.7. Subqueries

Subqueries in the following context can be hinted using the `ANY_subquery` name.

```
IN (SELECT ... {LIMIT | OFFSET ...} ...)
= ANY (SELECT ... {LIMIT | OFFSET ...} ...)
= SOME (SELECT ... {LIMIT | OFFSET ...} ...)
```

For these syntaxes, the planner internally assigns a name to the subquery when planning joins on tables including it, so join hints are applicable on such joins using the implicit name as follows:

```
postgres=# /*+HashJoin(a1 ANY_subquery)*/
postgres=# EXPLAIN SELECT *
FROM pgbench_accounts a1
WHERE aid IN (SELECT bid FROM pgbench_accounts a2 LIMIT 10);
        QUERY PLAN

-----
Hash Semi Join  (cost=0.49..2903.00 rows=1 width=97)
  Hash Cond: (a1.aid = a2.bid)
    -> Seq Scan on pgbench_accounts a1  (cost=0.00..2640.00 rows=100000 width=97)
    -> Hash  (cost=0.36..0.36 rows=10 width=4)
        -> Limit  (cost=0.00..0.26 rows=10 width=4)
            -> Seq Scan on pgbench_accounts a2  (cost=0.00..2640.00 rows=100000
width=4)
```

F.37.7.1. Using IndexOnlyScan Hint

The index scan may be unexpectedly performed on another index when the index specified in the `IndexOnlyScan` hint cannot perform the index-only scan.

F.37.7.2. Behavior of NoIndexScan

The `NoIndexScan` hint involves `NoIndexOnlyScan`.

F.37.7.3. Parallel Hint and UNION

A `UNION` can run in parallel only when all underlying subqueries are parallel-safe. Conversely, enforcing parallel on any of the subqueries allows a parallel-executable `UNION` to run in parallel. Meanwhile, the `Parallel` hint with zero workers inhibits a scan from being executed in parallel.

F.37.7.4. Setting pg_hint_plan Parameters by Set Hints

`pg_hint_plan` parameters change the behavior of itself, so some parameters do not work as expected.

- Hints to change `enable_hint`, `enable_hint_table` are ignored even though they are reported as “used hints” in debug logs.
- Setting `debug_print` and `message_level` starts working in the middle of the target query processing.

F.37.8. Errors

`pg_hint_plan` stops parsing on any error and uses hints already parsed in most cases. Typical errors are listed below.

F.37.8.1. Syntax Errors

Any syntactical errors or wrong hint names are reported as syntax errors. These errors are reported in the server log with the message level, which is specified by `pg_hint_plan.message_level` if `pg_hint_plan.debug_print` is on or above.

F.37.8.2. Object Misspecifications

Hints with object misspecifications are simply ignored. This kind of error is reported as “not used hints” in the server log under the same conditions as syntax errors.

F.37.8.3. Redundant or Conflicting Hints

The last hint will take effect in case of redundant or conflicting hints. This kind of error is reported as “duplication hints” in the server log under the same conditions as syntax errors.

F.37.8.4. Nested Comments

A hint comment cannot contain another block comment. If `pg_hint_plan` finds it, unlike other errors, it will stop parsing and abandon all hints already parsed. This kind of error is reported in the same manner as other errors.

F.37.9. Functional Limitations

F.37.9.1. Influences of Some of Planner GUC Parameters

The planner does not try to consider joining order for the `FROM` clause entries more than `from_collapse_limit`. In such cases `pg_hint_plan` cannot affect joining order as expected.

F.37.9.2. Hints Trying to Enforce Inexecutable Plans

The planner selects any executable plan when the enforced plan cannot be executed.

- `FULL OUTER JOIN` to use nested loop
- To use indexes that do not have columns used in `quals`
- To do TID scans for queries without `ctid` conditions

F.37.9.3. Queries in ECPG

ECPG removes comments from queries written as embedded SQL, so hints cannot be passed from those queries. The only exception is that the `EXECUTE` command passes a given string unmodified. Consider hint tables for this case.

F.37.9.4. Work with `pg_stat_statements`

`pg_stat_statements` generates a query ID ignoring comments. As the result, the identical queries with different hints are summarized as the same query.

F.37.10. Available Hints

The available hints are listed below.

Table F.26. Hints List

Group	Format	Description
Scan method	<code>SeqScan(<i>table</i>)</code>	Forces the sequential scan on a table.
	<code>TidScan(<i>table</i>)</code>	Forces the TID scan on a table.
	<code>IndexScan(<i>table</i>[<i>index</i>...])</code>	Forces the index scan on a table. Restricts to specified indexes, if any.
	<code>IndexOnlyScan(<i>table</i>[<i>index</i>...])</code>	Forces the index-only scan on a table. Restricts to specified indexes, if any. The index scan may be used if the index-only scan is not available.
	<code>BitmapScan(<i>table</i>[<i>index</i>...])</code>	Forces the bitmap scan on a table. Restricts to specified indexes, if any.
	<code>IndexScanRegexp(<i>table</i>[<i>POSIX regexp</i>...])</code>	Forces the index scan on a table. Restricts to indexes that match the specified POSIX regular expression .
	<code>IndexOnlyScanRegexp(<i>table</i>[<i>POSIX regexp</i>...])</code>	Forces the index-only scan on a table. Restricts to indexes that match the specified POSIX regular expression .
	<code>BitmapScanRegexp(<i>table</i>[<i>POSIX regexp</i>...])</code>	Forces the bitmap scan on a table. Restricts to indexes that match the specified POSIX regular expression .
	<code>NoSeqScan(<i>table</i>)</code>	Forces the deactivation of the sequential scan on a table.
	<code>NoTidScan(<i>table</i>)</code>	Forces the deactivation of the TID scan on a table.
	<code>NoIndexScan(<i>table</i>)</code>	Forces the deactivation of the index scan and index-only scan on a table.
	<code>NoIndexOnlyScan(<i>table</i>)</code>	Forces the deactivation of the index-only scan on a table.
	<code>NoBitmapScan(<i>table</i>)</code>	Forces the deactivation of the bitmap scan on a table.
Join method	<code>NestLoop(<i>table table</i>[<i>table</i>...])</code>	Forces the nested loop for joins with specified tables.
	<code>HashJoin(<i>table table</i>[<i>table</i>...])</code>	Forces the hash join for joins with specified tables.

Group	Format	Description
	<code>MergeJoin(table table[table...])</code>	Forces the merge join for joins with specified tables.
	<code>NoNestLoop(table table[table...])</code>	Forces the deactivation of the nested loop for joins with specified tables.
	<code>NoHashJoin(table table[table...])</code>	Forces the deactivation of the hash join for joins with specified tables.
	<code>NoMergeJoin(table table[table...])</code>	Forces the deactivation of the merge join for joins with specified tables.
Join order	<code>Leading(table table[table...])</code>	Forces the join order as specified.
	<code>Leading(<join pair>)</code>	Forces the join order and directions as specified. A join pair is a pair of tables and/or other join pairs enclosed in parentheses, which can make a nested structure.
Row number correction	<code>Rows(table table[table...] correction)</code>	Corrects row number of a result of the joins with the specified tables. The available correction methods are absolute (<code>#<n></code>), addition (<code>+<n></code>), subtraction (<code>-<n></code>) and multiplication (<code>*<n></code>). <code><n></code> should be a string that <code>strtod()</code> can read.
Parallel query configuration	<code>Parallel(table <# of workers> [soft hard])</code>	Enforces or inhibits parallel execution of the specified table. <code><# of workers></code> is the desired number of parallel workers, where zero means inhibiting parallel execution. If the third parameter is <code>soft</code> (default), it only changes <code>max_parallel_workers_per_gather</code> and leaves everything else to the planner. The <code>hard</code> value enforces the specified number of workers.
GUC	<code>Set(GUC-parameter value)</code>	Sets the GUC parameter to the value while planner is running.

F.38. pg_pathman**Important**

Starting from Postgres Pro 12, using `pg_pathman` is not recommended. Use vanilla declarative partitioning instead, as described in [Section 5.11](#).

The `pg_pathman` is a Postgres Pro extension that provides an optimized partitioning solution for large and distributed databases. Using `pg_pathman`, you can:

- Partition large databases without downtime.
- Speed up query execution for partitioned tables.
- Manage existing partitions and add new partitions on the fly.
- Add foreign tables as partitions.
- Join partitioned tables for read and write operations.

The extension is compatible with Postgres Pro 9.5 or higher.

F.38.1. Installation and Setup

The `pg_pathman` extension is included into the Postgres Pro. Once you have Postgres Pro installed, complete the following steps to enable `pg_pathman`:

1. Add `pg_pathman` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_pathman'
```

Important

`pg_pathman` may have conflicts with other extensions that use the same hook functions. For example, `pg_pathman` may interfere with the `pg_stat_statements` extension as they both use `ProcessUtility_hook`. To avoid such issues, `pg_pathman` must always be the last in the list of libraries: `shared_preload_libraries = 'pg_stat_statements, pg_pathman'`

2. Restart the Postgres Pro instance for the settings to take effect.
3. Create the `pg_pathman` extension as follows:

```
CREATE SCHEMA pathman;  
GRANT USAGE ON SCHEMA pathman TO PUBLIC;  
CREATE EXTENSION pg_pathman WITH SCHEMA pathman;
```

Important

To ensure that your calls to `pg_pathman`'s functions are always secure against `search_path`-based attacks (see [CREATE EXTENSION](#) for details), install it only into a clean schema where nobody except superusers has the `CREATE` privilege for database objects.

Once `pg_pathman` is enabled, you can start partitioning tables.

Note

During installation, `pg_pathman` creates a few RLS policies to restrict access to its own tables. Postgres Pro core, however, does not support dump/restore of databases where extensions issuing `CREATE POLICY` statements are installed. Therefore, when restoring a dump of a database where `pg_pathman` is installed, you will get error messages such as:

```
ERROR: policy "allow_select" for table "pathman_config" already exists
```

Ignore them since they do not affect whether the data being restored is complete.

Tip

You can also build `pg_pathman` from source code by executing the following command in the `pg_pathman` directory:

```
make install USE_PGXS=1
```

When this operation is complete, follow the steps described above to complete the setup.

In addition, do not forget to set the `PG_CONFIG` variable if you want to test `pg_pathman` on a custom build of Postgres Pro. For details, see [Building and Installing PostgreSQL Extension Modules](#).

You can toggle `pg_pathman` or its specific custom nodes on and off using GUC variables. For details, see [Section F.38.5.1](#).

If you want to permanently disable `pg_pathman` for a previously partitioned table, use the `disable_pathman_for()` function:

```
SELECT disable_pathman_for('range_rel');
```

All sections and data will remain unchanged and will be handled by the standard Postgres Pro inheritance mechanism.

F.38.1.1. Updating `pg_pathman`

If you already have a previous version of `pg_pathman` installed, complete the following steps to upgrade to a newer version:

1. Install Postgres Pro.
2. Restart your Postgres Pro cluster.
3. If you are running a previous major version of `pg_pathman` (the second digit in the version number is different), complete the update as follows:

```
ALTER EXTENSION pg_pathman UPDATE TO version;  
SET pg_pathman.enable = t;
```

where *version* is the `pg_pathman` major version number, such as 1.5.

You can check the current `pg_pathman` version by running the `pathman_version()` function.

F.38.2. Usage

[Choosing Partitioning Strategies](#)

[Running Non-Blocking Data Migration](#)

[Partitioning by a Single Expression](#)

[Partitioning by Composite Key](#)

[Running Multilevel Partitioning](#)

[Using Declarative Syntax](#)

[Managing Partitions](#)

As your database grows, indexing mechanisms may become inefficient and cause high latency as you run queries. To improve performance, ensure scalability, and optimize database administration processes you can use partitioning — splitting a large table into smaller pieces, with each row moved to a single partition according to the partitioning key.

Traditionally, Postgres Pro has supported partitioning via table inheritance, with each partition created as a child table with a CHECK constraint. In Postgres Pro 10, support for [declarative partitioning](#)

was added, which also relies on inheritance. With these approaches, the query planner has to perform an exhaustive search and check constraints on each partition to build a query plan, which may slow down queries for tables with a large number of partitions. The `pg_pathman` extension uses an optimized planning algorithms and partitioning functions based on the internal structure of the partitioned tables, which allows to achieve better performance results. For details on `pg_pathman` implementation specifics, see [Section F.38.4](#).

F.38.2.1. Choosing Partitioning Strategies

The `pg_pathman` extension supports the following partitioning strategies:

- Hash — maps rows to partitions using a generic hash function. Choose this strategy if most of your queries will be of the exact-match type.
- Range — maps rows to partitions based on partitioning key ranges assigned to each partition. Choose this strategy if your database contains numeric data that you are likely to query or manage by ranges. For example, you may want to query historical data by years, or review experiment results by specific numeric ranges. To achieve performance gains, `pg_pathman` uses the binary search algorithm.

By default, `pg_pathman` migrates all data from the parent table to the newly created partitions at once (*blocking partitioning*). This approach enables you to restructure the table in a single transaction, but may cause downtime if you have a lot of data. If it is critical to avoid downtime, you can use *concurrent partitioning*. In this case, `pg_pathman` writes all the updates to the newly created partitions, but keeps the original data in the parent table until you explicitly migrate it. This enables you to partition large databases without downtime, as you can choose convenient time for migration and copy data in small batches without blocking other transactions. For details on concurrent partitioning, see [Section F.38.2.2](#).

F.38.2.1.1. Setting up Hash Partitioning

To perform hash partitioning with `pg_pathman`, run the `create_hash_partitions()` function:

```
create_hash_partitions(parent_relid      REGCLASS,  
                      expression        TEXT,  
                      partitions_count  INTEGER,  
                      partition_data    BOOLEAN DEFAULT TRUE,  
                      partition_names   TEXT[]  DEFAULT NULL,  
                      tablespaces       TEXT[]  DEFAULT NULL)
```

The `pg_pathman` module creates the specified number of partitions based on the hash function. Optionally, you can specify partition names and tablespaces by setting `partition_names` and `tablespaces` options, respectively.

You cannot add or remove partitions after the parent table is split. If required, you can replace the specified partition with another table:

```
replace_hash_partition(old_partition    REGCLASS,  
                      new_partition    REGCLASS,  
                      lock_parent      BOOL DEFAULT TRUE);
```

When set to `true`, `lock_parent` parameter will prevent any `INSERT/UPDATE/ALTER TABLE` queries to parent table.

If you omit the optional `partition_data` parameter or set it to `true`, all the data from the parent table gets migrated to partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.38.2.2](#).

F.38.2.1.2. Setting up Range Partitioning

The `pg_pathman` module provides the `create_range_partitions()` for range partitioning. This function creates partitions based on the specified interval and the initial partitioning key value. New partitions are created automatically when you insert data outside of the already covered range.

```
create_range_partitions(parent_relid REGCLASS,  
                        expression TEXT,  
                        start_value ANYELEMENT,  
                        p_interval ANYELEMENT | INTERVAL,  
                        p_count INTEGER DEFAULT NULL,  
                        partition_data BOOLEAN DEFAULT TRUE)
```

The `pg_pathman` module creates partitions based on the specified parameters. If you omit the optional `p_count` parameter, `pg_pathman` calculates the required number of partitions based on the specified start value and interval. If you insert new data outside of the existing partition range, `pg_pathman` creates new partitions automatically, keeping the specified interval. This approach ensures that all partitions are of the same size, which can improve query performance and facilitate database management.

Alternatively, you can specify an array defining the bounds of partitions to be created using the `bounds` parameter:

```
create_range_partitions(parent_relid REGCLASS,  
                        expression TEXT,  
                        bounds ANYARRAY,  
                        partition_names TEXT[] DEFAULT NULL,  
                        tablespaces TEXT[] DEFAULT NULL,  
                        partition_data BOOLEAN DEFAULT TRUE)
```

If required, you can also use [partition management functions](#) to add partitions manually. For example, if there is a gap between the created partitions, `pg_pathman` cannot fill it with a new partition in an automated mode.

By default, all the data from the parent table gets migrated to the specified number of partitions. The `pg_pathman` module blocks the table for other transactions until data migration completes. To avoid downtime, you can set the `partition_data` parameter to `false` and later use the `partition_table_concurrently()` function to migrate your data to partitions without blocking other queries. For details, see the [Section F.38.2.2](#).

F.38.2.2. Running Non-Blocking Data Migration

If it is critical to avoid downtime, you can perform concurrent partitioning by setting the `partition_data` parameter of the partitioning function to `false`. In this case, `pg_pathman` creates empty partitions, keeping all the original data in the parent table. At the same time, all the database updates are written to the newly created partitions. You can later migrate the original data to partitions without blocking other queries using the `partition_table_concurrently()` function:

```
partition_table_concurrently(relation REGCLASS,  
                             batch_size INTEGER DEFAULT 1000,  
                             sleep_time FLOAT8 DEFAULT 1.0)
```

where:

- `relation` is the parent table.
- `batch_size` is the number of rows to copy from the parent table to partitions at a time. You can set this parameter to any integer value from 1 to 10000.
- `sleep_time` is the time interval between migration attempts, in seconds.

The `pg_pathman` module starts a background worker to move the data from the parent table to partitions in small batches of the specified `batch_size`. If one or more rows in the batch are locked by other queries, `pg_pathman` waits for the specified `sleep_time` and tries again, up to 60 times. You can monitor the migration process in the `pathman_concurrent_part_tasks` view that shows the number of rows migrated so far:

```
[user]postgres: select * from pathman_concurrent_part_tasks ;  
userid | pid | dbid | relid | processed | status  
-----+-----+-----+-----+-----+-----  
user   | 20012 | 12413 | test  | 334000 | working
```

(1 row)

If you need to stop data migration, run the `stop_concurrent_part_task()` function at any time:

```
SELECT stop_concurrent_part_task(relation REGCLASS);
```

`pg_pathman` completes the migration of the current batch and terminates the migration process.

Tip

When `pg_pathman` migrates all the data from the parent table, you can exclude the parent table from the query plan. See the `set_enable_parent()` function description for details.

F.38.2.3. Partitioning by a Single Expression

For both range and hash partitioning strategies, `pg_pathman` supports partitioning by expression that returns a single scalar value. The partitioning expression can reference a table column, as well as calculate the partitioning key based on one or more column values.

Tip

If you would like to partition a table by a tuple, see [Section F.38.2.4](#).

To partition a table by expression, use `pg_pathman` [partitioning functions](#). The partitioning expression must satisfy the following conditions:

- Expression must reference at least one column of the partitioned table.
- All referenced columns must be marked as `NOT NULL`.
- Expression cannot reference system attributes, such as `oid`, `xmin`, `xmax`, etc.
- Expression cannot include subqueries.
- All functions used by expression must be marked as `IMMUTABLE`.

As the expression can return a value of virtually any type, make sure to convert it to the type you need for partitioning.

To access a partition, you must use the exact expression used for partitioning. Otherwise, `pg_pathman` cannot optimize the query. You can view the partitioning expression for each partitioned table in the `pathman_config` table.

F.38.2.3.1. Examples

Suppose you have the `test` table that stores some `jsonb` data:

```
CREATE TABLE test(col jsonb NOT NULL);
INSERT INTO test
SELECT format('{"key": %s, "date": "%s", "value": "%s"}',
             i, current_date, md5(i::text))::jsonb
FROM generate_series(1, 10000 * 10) as g(i);
```

To partition this data by range of the `key` value, you need to extract this value from the `jsonb` object and convert it to a numeric type, such as `bigint`:

```
SELECT create_range_partitions('test', '(col->>'key')::bigint', 1, 10000, 10);
```

`pg_pathman` splits the parent table into ten partitions, with each partition storing 10000 rows:

```
SELECT * FROM pathman_partition_list;
parent | partition | parttype | expr | range_min | range_max
-----+-----+-----+-----+-----+-----
+-----+
test   | test_1    |          |      | 1          | 10001
```

```
test | test_2 | 2 | ((col ->> 'key'::text))::bigint | 10001 | 20001
test | test_3 | 2 | ((col ->> 'key'::text))::bigint | 20001 | 30001
test | test_4 | 2 | ((col ->> 'key'::text))::bigint | 30001 | 40001
test | test_5 | 2 | ((col ->> 'key'::text))::bigint | 40001 | 50001
test | test_6 | 2 | ((col ->> 'key'::text))::bigint | 50001 | 60001
test | test_7 | 2 | ((col ->> 'key'::text))::bigint | 60001 | 70001
test | test_8 | 2 | ((col ->> 'key'::text))::bigint | 70001 | 80001
test | test_9 | 2 | ((col ->> 'key'::text))::bigint | 80001 | 90001
test | test_10 | 2 | ((col ->> 'key'::text))::bigint | 90001 | 100001
(10 rows)
```

F.38.2.4. Partitioning by Composite Key

Using `pg_pathman`, you can also perform range partitioning by composite key. A composite key consists of two or more comma-separated values, which can be columns or expressions extracting the values from the table. The expressions defining the composite key must satisfy the conditions described in [Section F.38.2.3](#).

Although `pg_pathman` does not support automatic partition creation by composite key, you can add partitions using the `add_range_partition()` function. A typical workflow is as follows:

1. Enable automatic partition naming for your table by running the `create_naming_sequence()` function.
2. Create a composite partitioning key.
3. Register a table you are going to partition with `pg_pathman` using the `add_to_pathman_config()` function.
4. Add a partition based on the defined composite partitioning key using the `add_range_partition()` function.

F.38.2.4.1. Examples

Suppose you have the `test` table that stores some temporal data:

```
CREATE TABLE test (logdate date NOT NULL, comment text);
```

To partition this data by month and year, you have to create a composite key:

```
CREATE TYPE test_key AS (year float8, month float8);
```

To enable automatic partition naming, run the `create_naming_sequence()` function passing the table name as an argument:

```
SELECT create_naming_sequence('test');
```

Register the `test` table with `pg_pathman`, specifying the partitioning key you are going to use:

```
SELECT add_to_pathman_config('test',
                             '( extract(year from logdate),
                               extract(month from logdate) )::test_key',
                             NULL);
```

Create a partition that includes all the data in the range of ten years, starting from January of the current year:

```
SELECT add_range_partition('test',
                           (extract(year from current_date), 1)::test_key,
                           (extract(year from current_date + '10 years'::interval),
                             1)::test_key);
```

F.38.2.5. Running Multilevel Partitioning

`pg_pathman` supports multilevel partitioning for both hash and range partitioning strategies. You can use partitioning strategies in any combination: a hash- or range-partitioned table can be further partitioned by both hash or range.

To split an existing partition into several child ones, use the regular `pg_pathman` partitioning functions as explained in [Section F.38.2.1](#), passing the name of the partition to be split as the `parent_relid` parameter. You can check the exact partition names in the [pathman_partition_list](#) view.

When opting for the range-range partitioning combination, you can either choose a different partitioning expression, or use the same expression as for the parent table. In the latter case, if the selected range is larger than that of the parent partition, only those child partitions that intersect with the parent range will be in use. Other child partitions will remain empty unless their parent is merged with an adjacent partition that covers at least a part of their range.

F.38.2.5.1. Examples

Suppose you have the `journal` table with some logs, which is partitioned by month:

```
-- create an empty table
CREATE TABLE journal (
  id      SERIAL,
  dt      TIMESTAMP NOT NULL,
  level   INTEGER,
  msg     TEXT);

-- generate some log data into the table
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;

-- partition the table by range
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1
  month'::interval);
```

If having smaller partitions makes more sense at some point, you can further split the partitions by hash or range. For example, to split the `journal_1` partition into subpartitions by day, run:

```
SELECT create_range_partitions('journal_1', 'dt', '2015-01-01'::date, '1
  day'::interval);
```

Similarly, you can use hash partitioning to create child partitions. For example, split the `journal_2` partition into five partitions by hash using the `id` column as the partitioning key:

```
SELECT create_hash_partitions('journal_2', 'id', '5');
```

F.38.2.6. Using Declarative Syntax

Declarative syntax for partitioning enables you to define the partitioning strategy when creating a table, as well as partition existing tables and manage table partitions using SQL commands. Postgres Pro Enterprise offers the following implementations of declarative syntax:

- Postgres Pro core functionality, described in detail in [Section 5.11.2](#).
- `pg_pathman` implementation of declarative syntax.

Depending on the chosen implementation, the available SQL command forms will differ, as explained in [CREATE TABLE](#) and [ALTER TABLE](#) descriptions.

By default, Postgres Pro core functionality is used for declarative partitioning. To enable declarative partitioning provided by `pg_pathman`, set the [partition_backend](#) parameter to the `pg_pathman` value. In this case, you can use declarative range and hash partitioning strategies as explained below. For the [CREATE TABLE](#) command, you can also override the [partition_backend](#) setting by specifying the `USING partition_backend` clause. Do not confuse this clause with `USING method`, which cannot be used when creating partitioned tables.

When running the `CREATE TABLE` command, you can use the `PARTITION BY` clause to split the resulting table into partitions by range or hash.

To create a table partitioned by range, specify the partition names, the range of values to include into each partition and, optionally, a tablespace. For example:

```
CREATE TABLE abc(id serial NOT NULL)
  PARTITION BY RANGE(id)
  (
    PARTITION abc_100 VALUES LESS THAN (100) TABLESPACE ts1,
    PARTITION abc_200 VALUES LESS THAN (200) TABLESPACE ts2
  );
```

When creating a table partitioned by hash, you can either specify the number of partitions to create, or the exact partitions and tablespaces. For example, to create the `abc` table with three partitions, run:

```
CREATE TABLE abc(id serial NOT NULL)
  PARTITION BY HASH (id) PARTITIONS (3);
```

To define the exact partitions to create, use the following statement:

```
CREATE TABLE abc(id serial NOT NULL)
  PARTITION BY HASH (id)
  (
    PARTITION abc_first TABLESPACE ts1,
    PARTITION abc_second TABLESPACE ts2
  );
```

To partition an already created table, you can use the `ALTER TABLE` command with the `PARTITION BY` clause. For example, to split the `abc` table into three hash partitions, run:

```
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3);
```

When performing range partitioning of an already created table, you have to specify the lower bound of the first partition, which must not be greater than the smallest value in the partition key column, and provide the partitioning interval that defines the range of values to include into a single partition:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (2000);
```

If the table to partition contains a lot of data and it is critical to avoid downtime, consider using the optional `CONCURRENTLY` clause. In this case, `pg_pathman` first creates empty partitions, and then migrates the data in batches of 1000 rows. This clause can be used for both hash and range partitioning. For example:

```
ALTER TABLE abc PARTITION BY RANGE (id) START FROM (0) INTERVAL (50000) CONCURRENTLY;
ALTER TABLE abc PARTITION BY HASH (id) PARTITIONS (3) CONCURRENTLY;
```

`pg_pathman` declarative syntax also supports multilevel partitioning. Once the table is partitioned, you can run the `ALTER TABLE` command with the `PARTITION BY` clause on the partition that you would like to split. Consider the following example with hash partitioning:

```
CREATE TABLE test(a int NOT NULL, b int NOT NULL)
  PARTITION BY by hash(a) PARTITIONS (8);

ALTER TABLE test_1
  PARTITION BY hash(b) PARTITIONS (10);
```

As a result, the `test` table is split into eight hash partitions, and its `test_1` partition is further split into ten partitions by another key.

The `ALTER TABLE` command can also be run with partition management clauses to add, remove, or modify partitions, as explained in [ALTER TABLE](#). You can perform these actions on tables partitioned with `pg_pathman` regardless of the [partition_backend](#) setting.

F.38.2.7. Managing Partitions

`pg_pathman` provides multiple functions for easy partition management. For details, see [Section F.38.5.3.4](#).

F.38.3. Examples

F.38.3.1. Common Tips

- You can add `partition` column containing the names of the underlying partitions using the system attribute called `tableoid`:

```
SELECT tableoid::regclass AS partition, * FROM partitioned_table;
```

- Though indices on a parent table are not particularly useful (since the parent table is supposed to be empty), they act as prototypes for indices on partitions. For each index on the parent table, `pg_pathman` creates a similar index on each partition.
- All running concurrent partitioning tasks can be listed using the `pathman_concurrent_part_tasks` view:

```
SELECT * FROM pathman_concurrent_part_tasks;
userid | pid | dbid | relid | processed | status
-----+-----+-----+-----+-----+-----
user   | 7367 | 16384 | test  | 472000    | working
(1 row)
```

- The `pathman_partition_list` in conjunction with `drop_range_partition()` can be used to drop range partitions in a more flexible way compared to `DROP TABLE`:

```
SELECT drop_range_partition(partition, false) /* move data to parent */
FROM pathman_partition_list
WHERE parent = 'part_test'::regclass AND range_min::int < 500;
NOTICE:  1 rows copied from part_test_11
NOTICE: 100 rows copied from part_test_1
NOTICE: 100 rows copied from part_test_2
drop_range_partition
-----
dummy_test_11
dummy_test_1
dummy_test_2
(3 rows)
```

- You can turn foreign tables into partitions using the `attach_range_partition()` function. Rows that were meant to be inserted into the parent will be redirected to foreign partitions using `PartitionFilter`. By default, it is only allowed to insert rows into partitions provided by `postgres_fdw`. This setting is controlled by the `pg_pathman.insert_into_fdw` variable. You must have superuser rights to change this setting.

F.38.3.2. Hash Partitioning

Consider an example of hash partitioning. First create a table with an integer column:

```
CREATE TABLE items (
id          SERIAL PRIMARY KEY,
name        TEXT,
code        BIGINT);

INSERT INTO items (id, name, code)
SELECT g, md5(g::text), random() * 100000
FROM generate_series(1, 100000) as g;
```

Now run the `create_hash_partitions()` function with appropriate arguments:

```
SELECT create_hash_partitions('items', 'id', 100);
```

This will create new partitions and move the data from the parent table to partitions.

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM items WHERE id = 1234;
 id | name | code
-----+-----+-----
1234 | 81dc9bdb52d04dc20036dbd8313ed055 | 1855
(1 row)
```

```
EXPLAIN SELECT * FROM items WHERE id = 1234;
QUERY PLAN
```

```
-----
Append  (cost=0.28..8.29 rows=0 width=0)
->  Index Scan using items_34_pkey on items_34  (cost=0.28..8.29 rows=0 width=0)
Index Cond: (id = 1234)
```

Notice that the Append node contains only one child scan, which corresponds to the WHERE clause.

Important

Pay attention to the fact that `pg_pathman` excludes the parent table from the query plan.

To access the parent table, use the ONLY modifier:

```
EXPLAIN SELECT * FROM ONLY items;
QUERY PLAN
-----
Seq Scan on items  (cost=0.00..0.00 rows=1 width=45)
```

F.38.3.3. Range Partitioning

Consider an example of range partitioning. Let's create a table containing some dummy logs:

```
CREATE TABLE journal (
id      SERIAL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT);

-- similar index will also be created for each partition
CREATE INDEX ON journal(dt);

-- generate some data
INSERT INTO journal (dt, level, msg)
SELECT g, random() * 6, md5(g::text)
FROM generate_series('2015-01-01'::date, '2015-12-31'::date, '1 minute') as g;
```

Run the `create_range_partitions()` function to create partitions so that each partition would contain the data for one day:

```
SELECT create_range_partitions('journal', 'dt', '2015-01-01'::date, '1 day'::interval);
```

It will create 364 partitions and move the data from the parent table to partitions.

New partitions are appended automatically by insert trigger, but it can be done manually with the following functions:

```
-- add new partition with specified range
SELECT add_range_partition('journal', '2016-01-01'::date, '2016-01-07'::date);
```

```
-- append new partition with default range
SELECT append_range_partition('journal');
```

The first one creates a partition with specified range. The second one creates a partition with default interval and appends it to the partition list. It is also possible to attach an existing table as partition. For example, we may want to attach an archive table (or even foreign table from another server) for some outdated data:

```
CREATE FOREIGN TABLE journal_archive (
id      INTEGER NOT NULL,
dt      TIMESTAMP NOT NULL,
level   INTEGER,
msg     TEXT)
SERVER archive_server;
```

```
SELECT attach_range_partition('journal', 'journal_archive', '2014-01-01'::date,
'2015-01-01'::date);
```

Important

The attached table must have the same columns as the partitioned table, except for the dropped columns. The attached columns must have the same type, collation, and NOT NULL settings as the original columns.

To merge two adjacent partitions, use the `merge_range_partitions()` function:

```
SELECT merge_range_partitions('journal_archive', 'journal_1');
```

To split partition by value, use the `split_range_partition()` function:

```
SELECT split_range_partition('journal_366', '2016-01-03'::date);
```

To detach partition, use the `detach_range_partition()` function:

```
SELECT detach_range_partition('journal_archive');
```

Here is an example of the query performing filtering by partitioning key:

```
SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
id      |          dt          | level |          msg
-----+-----+-----+-----
217441  | 2015-06-01 00:00:00 |     2 | 15053892d993ce19f580a128f87e3dbf
217442  | 2015-06-01 00:01:00 |     1 | 3a7c46f18a952d62ce5418ac2056010c
217443  | 2015-06-01 00:02:00 |     0 | 92c8de8f82faf0b139a3d99f2792311d
...
(2880 rows)
```

```
EXPLAIN SELECT * FROM journal WHERE dt >= '2015-06-01' AND dt < '2015-06-03';
QUERY PLAN
```

```
-----
Append  (cost=0.00..58.80 rows=0 width=0)
-> Seq Scan on journal_152  (cost=0.00..29.40 rows=0 width=0)
-> Seq Scan on journal_153  (cost=0.00..29.40 rows=0 width=0)
(3 rows)
```

F.38.4. Internals

`pg_pathman` stores partitioning configuration in the `pathman_config` table; each row contains a single entry for a partitioned table (relation name, partitioning column and its type). During the initialization

stage the `pg_pathman` module caches some information about child partitions in the shared memory, which is used later for plan construction. Before a `SELECT` query is executed, `pg_pathman` traverses the condition tree in search of expressions like:

```
VARIABLE OP CONST
```

where `VARIABLE` is a partitioning key, `OP` is a comparison operator (supported operators are `=`, `<`, `<=`, `>`, `>=`), `CONST` is a scalar value. For example:

```
WHERE id = 150
```

Based on the partitioning type and condition's operator, `pg_pathman` searches for the corresponding partitions and builds the plan.

F.38.4.1. Custom Plan Nodes

`pg_pathman` provides a couple of *custom plan nodes* which aim to reduce execution time, namely:

- `RuntimeAppend` (overrides `Append` plan node)
- `RuntimeMergeAppend` (overrides `MergeAppend` plan node)
- `PartitionFilter` (drop-in replacement for `INSERT` triggers)
- `PartitionRouter` for cross-partition `UPDATE` queries instead of triggers

`PartitionFilter` acts as a *proxy node* for `INSERT`'s child scan, which means it can redirect output tuples to the corresponding partition:

```
EXPLAIN (COSTS OFF)
INSERT INTO partitioned_table
SELECT generate_series(1, 10), random();
      QUERY PLAN
-----
Insert on partitioned_table
-> Custom Scan (PartitionFilter)
    -> Subquery Scan on "*SELECT*"
        -> Result

(4 rows)
```

`PartitionRouter` is another proxy node used in conjunction with `PartitionFilter` to enable cross-partition `UPDATE` operations, for example, when you update any column of a partitioning key.

Important

The `PartitionRouter` node transforms cross-partition `UPDATE` commands into `DELETE + INSERT`. On Postgres Pro versions prior to 11, this operation is unsafe as `pg_pathman` cannot determine whether the updated row has been deleted or moved to another partition.

By default, `PartitionRouter` is disabled to avoid undesirable side effects. To enable this node, set the `pg_pathman.enable_partitionrouter` to on.

```
EXPLAIN (COSTS OFF)
UPDATE partitioned_table
SET value = value + 1 WHERE value = 2;
      QUERY PLAN
-----
Update on partitioned_table_0
-> Custom Scan (PartitionRouter)
    -> Custom Scan (PartitionFilter)
        -> Seq Scan on partitioned_table_0
            Filter: (value = 2)
```

(5 rows)

`RuntimeAppend` and `RuntimeMergeAppend` have much in common: they come in handy in a case when `WHERE` condition takes form of:

VARIABLE OP PARAM

This kind of expressions can no longer be optimized at planning time since the parameter's value is not known until the execution stage takes place. The problem can be solved by embedding the *WHERE condition analysis routine* into the original `Append`'s code, thus making it pick only required scans out of a whole bunch of planned partition scans. This effectively boils down to creation of a custom node capable of performing such a check.

There are at least several cases that demonstrate usefulness of these nodes:

```
/* create table we're going to partition */
CREATE TABLE partitioned_table(id INT NOT NULL, payload REAL);

/* insert some data */
INSERT INTO partitioned_table
SELECT generate_series(1, 1000), random();

/* perform partitioning */
SELECT create_hash_partitions('partitioned_table', 'id', 100);

/* create ordinary table */
CREATE TABLE some_table AS SELECT generate_series(1, 100) AS VAL;
```

- `id = (select ... limit 1)`

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Custom Scan (RuntimeAppend) (actual time=0.030..0.033 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.011..0.011 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.010..0.010 rows=1 loops=1)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual time=0.004..0.006
rows=1 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 9
Planning time: 1.131 ms
Execution time: 0.075 ms
(9 rows)
```

```
/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;
```

```
EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = (SELECT * FROM some_table LIMIT 1);
```

QUERY PLAN

```
-----
Append (actual time=0.196..0.274 rows=1 loops=1)
  InitPlan 1 (returns $0)
    -> Limit (actual time=0.005..0.005 rows=1 loops=1)
          -> Seq Scan on some_table (actual time=0.003..0.003 rows=1 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.014..0.014 rows=0 loops=1)
      Filter: (id = $0)
      Rows Removed by Filter: 6
```

```

-> Seq Scan on partitioned_table_1 (actual time=0.003..0.003 rows=0 loops=1)
    Filter: (id = $0)
    Rows Removed by Filter: 5
    ... /* more plans follow */
Planning time: 1.140 ms
Execution time: 0.855 ms
(306 rows)

```

- `id = ANY (select ...)`

```

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
                                QUERY PLAN
-----

```

```

Nested Loop (actual time=0.025..0.060 rows=4 loops=1)
-> Limit (actual time=0.009..0.011 rows=4 loops=1)
    -> Seq Scan on some_table (actual time=0.008..0.010 rows=4 loops=1)
-> Custom Scan (RuntimeAppend) (actual time=0.002..0.004 rows=1 loops=4)
    -> Seq Scan on partitioned_table_70 partitioned_table (actual
time=0.001..0.001 rows=10 loops=1)
    -> Seq Scan on partitioned_table_26 partitioned_table (actual
time=0.002..0.003 rows=9 loops=1)
    -> Seq Scan on partitioned_table_27 partitioned_table (actual
time=0.001..0.002 rows=20 loops=1)
    -> Seq Scan on partitioned_table_63 partitioned_table (actual
time=0.001..0.002 rows=9 loops=1)
Planning time: 0.771 ms
Execution time: 0.101 ms
(10 rows)

```

```

/* disable RuntimeAppend node */
SET pg_pathman.enable_runtimeappend = f;

```

```

EXPLAIN (COSTS OFF, ANALYZE) SELECT * FROM partitioned_table
WHERE id = any (SELECT * FROM some_table limit 4);
                                QUERY PLAN
-----

```

```

Nested Loop Semi Join (actual time=0.531..1.526 rows=4 loops=1)
  Join Filter: (partitioned_table.id = some_table.val)
  Rows Removed by Join Filter: 3990
-> Append (actual time=0.190..0.470 rows=1000 loops=1)
    -> Seq Scan on partitioned_table (actual time=0.187..0.187 rows=0 loops=1)
    -> Seq Scan on partitioned_table_0 (actual time=0.002..0.004 rows=6
loops=1)
    -> Seq Scan on partitioned_table_1 (actual time=0.001..0.001 rows=5
loops=1)
    -> Seq Scan on partitioned_table_2 (actual time=0.002..0.004 rows=14
loops=1)
... /* 96 scans follow */
    -> Materialize (actual time=0.000..0.000 rows=4 loops=1000)
        -> Limit (actual time=0.005..0.006 rows=4 loops=1)
            -> Seq Scan on some_table (actual time=0.003..0.004 rows=4 loops=1)
Planning time: 2.169 ms
Execution time: 2.059 ms
(110 rows)

```

- NestLoop **involving a partitioned table**, which is omitted since it's occasionally shown above.

To learn more about custom nodes, see Alexander Korotkov's [blog](#).

F.38.5. Reference

F.38.5.1. GUC Variables

There are several user-accessible [GUC](#) variables designed to toggle `pg_pathman` or its specific custom nodes on and off.

- `pg_pathman.enable` — enable/disable the `pg_pathman` module.

Default: on

- `pg_pathman.enable_runtimeappend` — toggle the `RuntimeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_runtimemergeappend` — toggle the `RuntimeMergeAppend` custom node on/off.

Default: on

- `pg_pathman.enable_partitionfilter` — toggle the `PartitionFilter` custom node on/off to enable/disable cross-partition `INSERT` operations.

Default: on

- `pg_pathman.enable_partitionrouter` — toggle the `PartitionRouter` custom node on/off to enable/disable cross-partition `UPDATE` operations.

Default: off

- `pg_pathman.enable_auto_partition` — toggle automatic partition creation on/off (per session).

Default: on

- `pg_pathman.enable_bounds_cache` — toggle bounds cache on/off.

Default: on

- `pg_pathman.insert_into_fdw` — allow `INSERT` operations into various foreign-data wrappers. Possible values: `disabled`, `postgres`, and `any_fdw`.

Default: `postgres`

- `pg_pathman.override_copy` — toggle `COPY` statement hooking on/off.

Default: on

F.38.5.2. Views and Tables

F.38.5.2.1. `pathman_config`

This table stores the list of partitioned tables. This is the main configuration storage.

```
CREATE TABLE IF NOT EXISTS pathman_config (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    attname          TEXT NOT NULL,  
    parttype         INTEGER NOT NULL,  
    range_interval   TEXT);
```

F.38.5.2.2. `pathman_config_params`

This table stores optional parameters that override standard `pg_pathman` behavior.

```
CREATE TABLE IF NOT EXISTS pathman_config_params (  
    partrel          REGCLASS NOT NULL PRIMARY KEY,  
    enable_parent    BOOLEAN NOT NULL DEFAULT TRUE,  
    auto             BOOLEAN NOT NULL DEFAULT TRUE,  
    init_callback    REGPROCEDURE NOT NULL DEFAULT 0,  
    spawn_using_bgw  BOOLEAN NOT NULL DEFAULT FALSE);
```

F.38.5.2.3. pathman_concurrent_part_tasks

This view lists all currently running concurrent partitioning tasks.

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_concurrent_part_tasks()
RETURNS TABLE (
    userid      REGROLE,
    pid         INT,
    dbid        OID,
    relid       REGCLASS,
    processed   INT,
    status      TEXT)
AS 'pg_pathman', 'show_concurrent_part_tasks_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_concurrent_part_tasks
AS SELECT * FROM show_concurrent_part_tasks();
```

F.38.5.2.4. pathman_partition_list

This view lists all existing partitions, as well as their parents and range boundaries (NULL for hash partitions).

```
-- helper SRF function
CREATE OR REPLACE FUNCTION show_partition_list()
RETURNS TABLE (
    parent      REGCLASS,
    partition   REGCLASS,
    parttype    INT4,
    expr        TEXT,
    range_min   TEXT,
    range_max   TEXT)
AS 'pg_pathman', 'show_partition_list_internal'
LANGUAGE C STRICT;

CREATE OR REPLACE VIEW pathman_partition_list
AS SELECT * FROM show_partition_list();
```

F.38.5.3. Functions**F.38.5.3.1. Partitioning Functions**

```
create_hash_partitions(parent_relid    REGCLASS,
                      expression      TEXT,
                      partitions_count INTEGER,
                      partition_data   BOOLEAN DEFAULT TRUE,
                      partition_names  TEXT[]  DEFAULT NULL,
                      tablespaces     TEXT[]  DEFAULT NULL)
```

Performs hash partitioning for relation by integer key expression. The `partitions_count` parameter specifies the number of partitions to create; it cannot be changed afterwards. If `partition_data` is `true`, all the data will be automatically migrated from the parent table to partitions. Note that data migration may take a while to finish and the table will be locked until transaction commits. See `partition_table_concurrently()` for a lock-free way to migrate data. Partition creation callback is invoked for each partition if set beforehand (see `set_init_callback()`).

```
create_range_partitions(relation      REGCLASS,
                      expression     TEXT,
                      start_value     ANYELEMENT,
                      p_interval      ANYELEMENT,
```

```

        p_count          INTEGER DEFAULT NULL,
        partition_data    BOOLEAN DEFAULT TRUE)

```

```

create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        start_value    ANYELEMENT,
                        p_interval     INTERVAL,
                        p_count        INTEGER DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)

```

```

create_range_partitions(relation      REGCLASS,
                        expression     TEXT,
                        bounds         ANYARRAY,
                        partition_names TEXT[] DEFAULT NULL,
                        tablespaces    TEXT[] DEFAULT NULL,
                        partition_data  BOOLEAN DEFAULT TRUE)

```

Performs range partitioning for `relation` by partitioning key defined by `expression`. The `start_value` argument specifies the initial value, `p_interval` sets the default range for automatically created partitions or partitions created with `append_range_partition()` or `prepend_range_partition()`. If `p_interval` is set to `NULL`, automatic partition creation is disabled. `p_count` is the number of premade partitions. If `p_count` is not set, than `pg_pathman` tries to determine the number of partitions based on the `expression` value. The `bounds` array defines the bounds for partitions to be created. You can build this array using the `generate_range_bounds()` function. Partition creation callback is invoked for each partition if set beforehand.

F.38.5.3.2. Data Migration Functions

```

partition_table_concurrently(relation REGCLASS,
                             batch_size INTEGER DEFAULT 1000,
                             sleep_time FLOAT8 DEFAULT 1.0)

```

Starts a background worker to move data from parent table to partitions. The worker utilizes short transactions to copy small batches of data (up to 10K rows per transaction) and thus doesn't significantly interfere with user's activity.

```

stop_concurrent_part_task(relation REGCLASS)

```

Stops a background worker performing a concurrent partitioning task. Note: worker will exit after it finishes relocating a current batch.

F.38.5.3.3. Triggers

Triggers are no longer required for `INSERT` and cross-partition `UPDATE` operations. However, user-supplied triggers are supported:

- Each inserted row results in execution of BEFORE/AFTER `INSERT` trigger functions of a corresponding partition.
- Each updated row results in execution of BEFORE/AFTER `UPDATE` trigger functions of a corresponding partition.
- Each moved row (cross-partition update) results in execution of BEFORE `UPDATE` + BEFORE/AFTER `DELETE` + BEFORE/AFTER `INSERT` trigger functions of corresponding partitions.

F.38.5.3.4. Partition Management Functions

```

replace_hash_partition(old_partition  REGCLASS,
                       new_partition  REGCLASS,
                       lock_parent    BOOLEAN DEFAULT TRUE)

```

Replaces the specified partition of hash-partitioned table with another table. When set to `true`, the `lock_parent` parameter prevents any `INSERT/UPDATE/ALTER TABLE` queries to the parent table.

```
split_range_partition(partition_relid REGCLASS,
                     split_value ANYELEMENT,
                     partition_name TEXT DEFAULT NULL,
                     tablespace TEXT DEFAULT NULL)
```

Split range partition in two by value, with the specified value included into the second partition. Partition creation callback is invoked for a new partition if available.

```
merge_range_partitions(variadic partitions REGCLASS[])
```

Merge several adjacent range partitions. Partitions are automatically ordered by increasing bounds. All the data will be accumulated in the first partition, while other merged partitions are removed. If the remaining partition has any child partitions, new child partitions for the merged data will be created as required using the same partitioning expression.

```
append_range_partition(parent_relid REGCLASS,
                      partition_name TEXT DEFAULT NULL,
                      tablespace TEXT DEFAULT NULL)
```

Append new range partition with `pathman_config.range_interval` as interval.

```
prepend_range_partition(parent_relid REGCLASS,
                      partition_name TEXT DEFAULT NULL,
                      tablespace TEXT DEFAULT NULL)
```

Prepend new range partition with `pathman_config.range_interval` as interval.

```
add_range_partition(parent_relid REGCLASS,
                   start_value ANYELEMENT,
                   end_value ANYELEMENT,
                   partition_name TEXT DEFAULT NULL,
                   tablespace TEXT DEFAULT NULL)
```

Create a new range partition for relation with the specified range bounds. If the `start_value` or the `end_value` is NULL, the corresponding range bound will be infinite.

```
drop_range_partition(partition_relid TEXT, delete_data BOOLEAN DEFAULT TRUE)
```

Drop range partition and all of its data if `delete_data` is true.

```
attach_range_partition(parent_relid REGCLASS,
                     partition_relid REGCLASS,
                     start_value ANYELEMENT,
                     end_value ANYELEMENT)
```

Attach partition to the existing range-partitioned relation. The attached table must have exactly the same structure as the parent table, including the dropped columns. Partition creation callback is invoked if set (see [Section F.38.5.2.2](#)).

```
detach_range_partition(partition_relid REGCLASS)
```

Detach partition from the existing range-partitioned relation.

```
disable_pathman_for(parent_relid REGCLASS)
```

Permanently disable `pg_pathman` partitioning mechanism for the specified parent table and remove the insert trigger if it exists. All partitions and data remain unchanged.

```
drop_partitions(parent_relid REGCLASS,
               delete_data BOOLEAN DEFAULT FALSE)
```

Drop partitions of the parent table (both foreign and local relations). If `delete_data` is false, the data is copied to the parent table first. Default is false.

F.38.5.3.5. Additional Functions

```
pathman_version()
```

Returns the `pg_pathman` version number.

```
set_interval(relation REGCLASS, value ANYELEMENT)
```

Update range-partitioned table interval. Note that interval must not be negative and it must not be trivial, i.e. its value should be greater than zero for numeric types, at least 1 microsecond for `timestamp` and at least 1 day for `date`.

```
set_enable_parent(relation REGCLASS, value BOOLEAN)
```

Include/exclude parent table into/from query plan. In original Postgres Pro planner parent table is always included into query plan even if it's empty, which can lead to additional overhead. You can use `disable_parent()` if you are never going to use parent table as a storage. Default value depends on the `partition_data` parameter specified during initial partitioning with the `create_range_partitions()` function. If the `partition_data` parameter was `true`, then all data have already been migrated to partitions and the parent table is disabled. Otherwise, it is enabled.

```
set_auto(relation REGCLASS, value BOOLEAN)
```

Enable/disable auto partition propagation (only for range partitioning). It is enabled by default.

```
set_init_callback(relation REGCLASS, callback REGPROCEDURE DEFAULT 0)
```

Set partition creation callback to be invoked for each attached or created partition (both hash and range). If callback is marked with `SECURITY INVOKER`, it is executed with the privileges of the user who produced a statement that has led to creation of a new partition. For example:

```
INSERT INTO partitioned_table VALUES (-5)
```

The callback must have the following signature: `part_init_callback(args JSONB) RETURNS VOID`. Parameter `arg` consists of several fields whose presence depends on partitioning type:

```
/* Range-partitioned table abc (child abc_4) */
{
    "parent":    "abc",
    "parttype":  "2",
    "partition": "abc_4",
    "range_max": "401",
    "range_min": "301"
}

/* Hash-partitioned table abc (child abc_0) */
{
    "parent":    "abc",
    "parttype":  "1",
    "partition": "abc_0"
}
```

```
set_spawn_using_bgw(relation REGCLASS, value BOOLEAN)
```

When inserting new data beyond the partitioning range, use `SpawnPartitionsWorker` to create new partitions in a separate transaction.

```
create_naming_sequence(parent_relid REGCLASS)
```

Enable automatic partition naming for the specified `relation` table. You must run this function when partitioning this table by composite key.

```
add_to_pathman_config(parent_relid    REGCLASS,  
                      expression      TEXT,  
                      range_interval  TEXT)  
add_to_pathman_config(parent_relid    REGCLASS,  
                      expression      TEXT)
```

Register the specified relation table with `pg_pathman` to enable partitioning by the provided expression. For range partitioning, the `range_interval` argument is mandatory. You can set it to `NULL` if you are going to add partition manually.

```
generate_range_bounds(p_start    ANYELEMENT,  
                     p_interval  INTERVAL,  
                     p_count     INTEGER)
```

```
generate_range_bounds(p_start    ANYELEMENT,  
                     p_interval  ANYELEMENT,  
                     p_count     INTEGER)
```

Build the `bounds` array that defines the bounds for partitions to be created. You can pass this array as an argument to the `create_range_partitions()` function.

F.39. pg_proaudit

The `pg_proaudit` extension enables detailed logging of various security events.

`pg_proaudit` works in parallel with the standard PostgreSQL logging solutions (logging collector) and does not depend on them. Security event log of the `pg_proaudit` extension is stored separately from the server log. At the Postgres Pro Enterprise startup, `pg_proaudit` launches a special background process to log security events.

Logging rules are stored in the `pg_proaudit.conf` configuration file located in the cluster data directory (PGDATA). It is a text file that can be edited directly using operating system facilities. To modify the file using SQL, you can use several `pg_proaudit` functions. The `pg_proaudit_settings` view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet.

All the logged events belong to the following classes:

- DDL commands for creating, changing, and deleting DBMS objects (databases, tablespaces, schemas, tables, views, sequences, languages, functions)
- access control commands for database objects (GRANT, REVOKE)
- DML commands for access to database objects (INSERT, UPDATE, DELETE, SELECT, TRUNCATE for tables and/or views, EXECUTE for functions)
- database authentication/disconnection events
- all commands executed by a particular user

Security events can be logged both in the centralized logging solution of the operating system (syslog) and in the standard file-system files. Event logs can be written both into the syslog and into the files simultaneously. For clear identification, all `pg_proaudit` records in the syslog are marked with `AUDIT`. Event log files are written in the CSV format. Each event is logged on a separate line that contains the following fields:

- date and time of the event
- username

- database name
- server process ID (PID)
- severity level: `INFO` or `ERROR`
- serial number of the command in a session
- subcommand number in complex commands (`CREATE TABLE ... AS SELECT ...`)
- operator name
- object type
- object name
- operator execution results: `SUCCESS` or `FAILURE`
- error message in case of `FAILURE`
- text of the SQL command
- parameters of the command (for example, for `PREPARE`)

You can define a directory to store security log files and set up log file rotation. `pg_proaudit` can switch to a new log file either after the specified time interval, or when the specified size of the log file is exceeded. This enables you to define a workflow for cleaning up security event logs.

Postgres Pro user with the `SUPERUSER` attribute should grant access to the `pg_proaudit` extension and security event log files only to the user with the information security administrator role.

F.39.1. Installing the `pg_proaudit` Extension

The `pg_proaudit` extension is a built-in extension included into Postgres Pro Enterprise. To enable `pg_proaudit`, complete the following steps:

1. Add `pg_proaudit` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_proaudit'
```

2. Reload the database server for the changes to take effect. To verify that the `pg_proaudit` library was installed correctly, you can run the following command:

```
SHOW shared_preload_libraries;
```

3. Create the `pg_proaudit` extension using the following query:

```
CREATE EXTENSION pg_proaudit;
```

The `pg_proaudit` extension adds several functions for managing the `pg_proaudit.conf` file, the `pg_proaudit_settings` view that displays the current `pg_proaudit` rules and event triggers. For convenience, the `pg_proaudit` extension should be created in each database for which you are going to log security events.

F.39.2. Uninstalling the `pg_proaudit` Extension

To properly uninstall `pg_proaudit`, complete the following steps:

1. Delete the `pg_proaudit` extension using the following query:

```
DROP EXTENSION pg_proaudit;
```

2. Remove `pg_proaudit` from the `shared_preload_libraries` variable in the `postgresql.conf` file.

Skip this step if you have several databases in the cluster and you want to remove the extension only for one of them. In this case, it is recommended to remove logging rules related to the corresponding database prior to uninstalling the extension.

F.39.3. Functions to Configure Security Event Logging

To configure security event logging, `pg_proaudit` provides an SQL interface that consists of several functions and the `pg_proaudit_settings` view.

```
pg_proaudit_set_rule(db_name text, event_type text, object_type text, object_name text,  
    role_name text, comment text)
```

Creates the logging rule with the specified parameters. When the `pg_proaudit_set_rule()` function completes, security event logging starts immediately, but the `pg_proaudit.conf` file is not updated. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- *db_name* — name of the database for which the logging rule is established. An empty string or NULL specified in this argument means that events are logged for all databases where the `pg_proaudit` extension is created. When set to [current_database\(\)](#), events for the current database are logged.
- *event_type* — type of the event that needs to be logged, including SQL operator names, as well as `AUTHENTICATE` and `DISCONNECT` events. When set to `ALL`, as well as when an empty string or NULL is specified, enables logging for all events available for the specified object type. For example, for the `TABLE` object type, the `ALL` keyword enables logging for commands `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `TRUNCATE`, `COPY`, as well as `CREATE`, `ALTER`, `DROP`. You can also set up logging of event classes by specifying the following values: `ALL_DDL`, `ALL_DML`, `ALL_MOD`, `ALL_PROC`, and `ALL_ROLE`. For the full list of possible *event_type* values, see [Section F.39.5](#).
- *object_type* — type of the object for which security events need to be logged. When set to `ALL`, as well as when an empty string or the NULL is specified, enables logging of events for all object types. For example, specify `FOREIGN TABLE` object type for the `SELECT` event to log all attempts to access foreign tables. Use NULL if *event_type* is set to `AUTHENTICATE`, `DISCONNECT`, `SET`, or `RESET`, and the `ROLE` value for all events that reference user actions, such as `CREATE USER` or `DROP USER`. The following object types are supported: `COMPOSITE TYPE`, `DATABASE`, `EVENT TRIGGER`, `FUNCTION`, `INDEX`, `PREPARED STATEMENT`, `ROLE`, `SEQUENCE`, `SCHEMA`, `TABLE`, `FOREIGN TABLE`, `TOAST TABLE`, `TABLESPACE`, `VIEW`, and `MATERIALIZED VIEW`.
- *object_name* — name of the object for which the logging rule is established. When an empty string or NULL is specified, enables logging of events for all object names.
- *role_name* — name of the role for which the logging rule is established. If specified, allows logging the actions caused by the specified DBMS user or the user who is directly or indirectly a member of this role. When an empty string or NULL is specified, enables logging of events for all role names. When set to [current_role](#), events for the current role are logged.
- *comment* — comment to describe the created logging rule. This argument does not affect the rule execution and is not reflected in the log.

```
pg_proaudit_remove_rule(db_name text, event_type text, object_type text, object_name  
    text, role_name text)
```

Removes the specific logging rule with the set parameters. To save the changes in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

Arguments:

- *db_name* — name of the database for which the logging rule needs to be removed.
- *event_type* — type of the event for which the logging rule needs to be removed. For the full list of possible *event_type* values, see [Section F.39.5](#).
- *object_type* — type of the object for which the logging rule needs to be removed.
- *object_name* — name of the object for which the logging rule needs to be removed.
- *role_name* — name of the role for which the logging rule needs to be removed.

```
pg_proaudit_show()
```

Returns logged events in a table view. This function is used by the `pg_proaudit_settings` view.

```
pg_proaudit_reload()
```

Reads logging configuration from the `pg_proaudit.conf` file. You must call this function if the `pg_proaudit.conf` file was modified manually using the operating system facilities.

```
pg_proaudit_reset()
```

Removes all logging rules. To save information about the canceled logging in the `pg_proaudit.conf` file, call the `pg_proaudit_save()` function.

```
pg_proaudit_save()
```

Saves logging rules from memory into the `pg_proaudit.conf` file. The `pg_proaudit.conf` file is located in the cluster data directory (PGDATA). You cannot change the `pg_proaudit.conf` file location.

F.39.4. pg_proaudit_settings View

This view displays the current `pg_proaudit` rules, even if they have not been saved into the `pg_proaudit.conf` file yet. The `pg_proaudit_settings` view consists of the following columns:

- `db_name` (text) — name of the database for which to log security events.
- `event_type` (text) — event type to log.
- `object_type` (text) — type of the object for which security events are to be logged.
- `object_name` (text) — name of the object for which security events are to be logged.
- `role_name` (text) — the role on behalf of which logged actions are performed.
- `comment` (text) — comment to describe the created logging rule.

F.39.5. Security Events

You can configure the `pg_proaudit` extension to log classes of security events and specific events by specifying the respective value in the `event_type` argument of the `pg_proaudit_set_rule()` function.

The following classes of security events are supported:

- `ALL_DDL`: CREATE, ALTER, DROP for any database object.
- `ALL_DML`: SELECT, INSERT, UPDATE, DELETE, TRUNCATE, EXECUTE for any table type as well as functions and stored procedures.
- `ALL_MOD`: INSERT, UPDATE, DELETE, TRUNCATE for any table type.
- `ALL_PROC`: CREATE, MODIFY, DROP for any function and stored procedure.
- `ALL_ROLE`: CREATE, ALTER, DROP for USER, ROLE, GROUP, as well as execution of the GRANT command.

The following specific security events are supported:

- AUTHENTICATE
- DISCONNECT
- ALTER AGGREGATE
- ALTER COLLATION
- ALTER CONVERSION
- ALTER DATABASE
- ALTER DEFAULT PRIVILEGES
- ALTER DOMAIN
- ALTER EVENT TRIGGER
- ALTER EXTENSION
- ALTER FOREIGN DATA WRAPPER
- ALTER FOREIGN TABLE
- ALTER FUNCTION
- ALTER INDEX
- ALTER LANGUAGE
- ALTER LARGE OBJECT
- ALTER MATERIALIZED VIEW
- ALTER OPERATOR
- ALTER OPERATOR CLASS
- ALTER OPERATOR FAMILY
- ALTER POLICY

- ALTER ROLE, ALTER USER, ALTER GROUP
- ALTER RULE
- ALTER SCHEMA
- ALTER SEQUENCE
- ALTER SERVER
- ALTER SYSTEM
- ALTER TABLE
- ALTER TABLESPACE
- ALTER TEXT SEARCH CONFIGURATION
- ALTER TEXT SEARCH DICTIONARY
- ALTER TEXT SEARCH PARSER

- SECURITY LABEL
- SELECT
- SET
- UPDATE
- TRUNCATE TABLE

F.39.6. Security Event Log Configuration Parameters

The `pg_proaudit` extension provides several configuration parameters for managing security event log files. These parameters can be set in the `postgresql.conf` configuration file, or with the help of the `ALTER SYSTEM` command. For the changes to take effect, call the `pg_reload_conf()` function or reload

the database server. For additional configuration, the `syslog_ident` and `syslog_facility` configuration parameters can be used.

`pg_proaudit.log_destination (string)`

Defines the method for logging security events. Possible values are:

- `csvlog` — log security events in a CSV file.
- `syslog` — log security events in syslog.

You can specify one or more values separated by commas.

Default: `csvlog`

`pg_proaudit.log_catalog_access (boolean)`

Specifies whether to log access to system catalog objects in the `pg_catalog` schema.

Default: `off`

`pg_proaudit.log_command_text (boolean)`

Specifies whether to log the SQL command text for security events.

Default: `on`

`pg_proaudit.log_directory (string)`

Specifies the path to the directory that stores CSV log files. This can be an absolute path, or a relative path to the cluster data directory (PGDATA). This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

Default: `pg_proaudit`

`pg_proaudit.log_filename (string)`

Defines the filenames of the created security event log files. The filename template can contain %-escapes, similar to the ones listed in the `strftime` specification of the Open Group (<http://pubs.opengroup.org/onlinepubs/009695399/functions/strftime.html>). This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

Default: `postgresql-%Y-%m-%d_%H%M%S.log`

`pg_proaudit.log_rotation_size (integer)`

Sets the maximum size of the CSV log file, in kilobytes. When this size is achieved, `pg_proaudit` creates a new file for logging security events. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog`. If set to 0, disables size-based creation of new log files.

Default: 10MB

`pg_proaudit.log_rotation_age (integer)`

Sets the maximum lifetime of a log file, in minutes. After this timeframe has elapsed, `pg_proaudit` creates a new file for logging security events. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value. If set to 0, disables time-based creation of new log files.

Default: 1 day

`pg_proaudit.log_truncate_on_rotation (boolean)`

Specifies whether to truncate log files when logging is switched to an existing log file. If set to `off`, `pg_proaudit` appends new log entries to the end of the file. This parameter is used if `pg_proaudit.log_destination` contains the `csvlog` value.

Default: off

F.39.7. Viewing Security Event Log

Security event log files are text files that can be viewed by the operating system facilities. To access log files using SQL, you can use the `file_fdw` extension — a foreign data wrapper for accessing files on the database server. To use this method, complete the following steps:

1. Install the `file_fdw` and create an external server:

```
CREATE EXTENSION file_fdw;
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

2. Create a foreign table, specifying the columns and the absolute path to the log file. The actual log file location is determined by the `pg_proaudit.log_directory` and `pg_proaudit.log_filename` parameters.

```
CREATE FOREIGN TABLE pg_proaudit_log
( log_time timestamp(3) with time zone,
  role_name text,
  database_name text,
  session_pid text,
  error_severity text,
  session_line_num bigint,
  session_line_subcommand_num bigint,
  event_type text,
  object_type text,
  object_name text,
  status text,
  error_message text,
  query_text text,
  query_args text )
SERVER pg_proauditlog
OPTIONS (filename 'absolute_file_path_to_log_file.csv', FORMAT 'csv' );
```

Make sure that the `pg_proaudit.log_destination` parameter contains the `csvlog` value, which enables writing security event logs to CSV files.

F.39.8. Examples

As an example, let's set up logging for the following security events:

- authentications/disconnections to the `postgres` database
- all actions of the `postgres` user
- creating, updating, and deleting any tables
- all operations on the `app_table` table that belongs to the `public` schema

All events must be logged in the CSV format and stored for a week. It is required to set up SQL access to the security event log. To complete the scenario, do the following:

In `psql`, check that the preliminary setup of the `pg_proaudit` extension is complete in the `postgres` database:

```
SHOW shared_preload_libraries;
shared_preload_libraries
-----
pg_proaudit

\dx pg_proaudit
               List of installed extensions
  Name          | Version | Schema | Description
```

```
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
pg_proaudit | 2.0      | public | provides auditing functionality
```

Add the following lines to the `postgresql.conf` configuration file:

```
pg_proaudit.log_destination = 'csvlog'
pg_proaudit.log_directory = 'audit'
pg_proaudit.log_filename = 'audit-%u.csv'
pg_proaudit.log_rotation_age = 1440
pg_proaudit.log_rotation_size = 0
pg_proaudit.log_truncate_on_rotation = on
pg_proaudit.log_command_text = on
```

For the changes to take effect, run the following query:

```
SELECT pg_reload_conf();
```

Check that the following parameters are set as expected:

```
SHOW pg_proaudit.log_destination;
SHOW pg_proaudit.log_directory;
SHOW pg_proaudit.log_filename;
SHOW pg_proaudit.log_rotation_age;
SHOW pg_proaudit.log_rotation_size;
SHOW pg_proaudit.log_truncate_on_rotation;
SHOW pg_proaudit.log_command_text;
```

Suppose your `PGDATA` environment variable points to the cluster data directory. Since the `pg_proaudit.log_directory` defines a relative path to the log files, they will be located in the `$PGDATA/audit` directory. Let's create an empty file for each day of the week and make them available to their owner only:

```
touch $PGDATA/audit/audit-1.csv
touch $PGDATA/audit/audit-2.csv
touch $PGDATA/audit/audit-3.csv
touch $PGDATA/audit/audit-4.csv
touch $PGDATA/audit/audit-5.csv
touch $PGDATA/audit/audit-6.csv
touch $PGDATA/audit/audit-7.csv
chmod 600 $PGDATA/audit/audit-*.csv
```

Create a table for reading log entries:

```
CREATE TABLE pg_proaudit_log (
    log_time timestamp(3) with time zone,
    role_name text,
    database_name text,
    session_pid text,
    error_severity text,
    session_line_num bigint,
    session_line_subcommand_num bigint,
    event_type text,
    object_type text,
    object_name text,
    status text,
    error_message text,
    query_text text,
    query_args text
);
```

Install the `file_fdw` extension and create an external server:

```
CREATE EXTENSION file_fdw;
```

```
CREATE SERVER pg_proauditlog FOREIGN DATA WRAPPER file_fdw;
```

Now let's create seven child foreign tables for the `pg_proaudit_log` table, for each day of the week:

```
CREATE FOREIGN TABLE pg_proaudit_log_1 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-1.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_2 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-2.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_3 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-3.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_4 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-4.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_5 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-5.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_6 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-6.csv', FORMAT 'csv');
CREATE FOREIGN TABLE pg_proaudit_log_7 () INHERITS (pg_proaudit_log) SERVER
pg_proauditlog
  OPTIONS (filename '/path_to_PGDATA/audit/audit-7.csv', FORMAT 'csv');
```

To set up logging for the required security events, connect to the postgres database and execute the following commands:

```
SELECT pg_proaudit_set_rule (current_database(), 'AUTHENTICATE', null, null, null, 'Any
authentication in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'DISCONNECT', null, null, null, 'Any
disconnect from the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', 'TABLE', null, null, 'Any
operations with any table in the current DB');
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, null, 'postgres', 'Any
operation by "postgres" user in the current DB');
```

Create the `app_table` table and enable logging for all operations on this table:

```
CREATE TABLE app_table (id int, name text);
SELECT pg_proaudit_set_rule (current_database(), 'ALL', null, 'public.app_table',
null);
```

Check that event logging is configured as expected:

```
SELECT * FROM pg_proaudit_settings;
```

db_name	event_type	object_type	object_name	role_name	comment
postgres	authenticate	ALL			Any authentication in the current DB
postgres	disconnect	ALL			Any disconnect from the current DB
postgres	ALL	table			Any operations with any table in the current DB
postgres	ALL	ALL		postgres	Any operation by "postgres" user in the current DB
postgres	ALL	ALL	public.app_table		

(5 rows)

Save these logging rules into the `pg_proaudit.conf` file, so that they are not lost after the server restart:

```
SELECT pg_proaudit_save();
```

Let's run several queries on the `app_table` table:

```
INSERT INTO app_table VALUES (1, 'first');
SELECT * FROM app_table;
```

Check the log entries for the `app_table` table:

```
SELECT to_char(log_time, 'DD.MM.YY HH24:MI:SS') AS when, role_name,
       session_pid, event_type, query_text
FROM   pg_proaudit_log
where  object_name = 'public.app_table';
       when      | role_name | session_pid | event_type |
       query_text
-----+-----+-----+-----+-----
27.09.23 12:44:27 | postgres | 2010        | CREATE TABLE | CREATE TABLE app_table
(id int, name text);
27.09.23 12:45:55 | postgres | 2010        | INSERT        | INSERT INTO app_table
VALUES (1, 'first');
27.09.23 12:46:00 | postgres | 2010        | SELECT        | SELECT * FROM app_table;
(3 rows)
```

We have set up a weekly rotation of log files, with the log file switched once a day. It means that queries to the `pg_proaudit_log` table will return only those security events that have happened in the latest week. Older events will be automatically removed at log file rotation. To define additional access constraints for specific log entries, you can create separate views based on queries to the `pg_proaudit_log` table and grant read rights to such views using built-in Postgres Pro access control methods.

F.40. pgpro_pwr — workload reports

The `pgpro_pwr` module is designed to discover most resource-intensive activities in your database. (PWR, pronounced like "power", is an abbreviation of Postgres Pro Workload Reporting.) This extension is based on Postgres Pro's [Statistics Collector](#) views and the [pgpro_stats](#) or [pg_stat_statements](#) extension.

Note

Although `pgpro_pwr` can work with the `pg_stat_statements` extension, it is recommended that you use the `pgpro_stats` extension since it provides statement plans, wait events sampling and load distribution statistics for databases, roles, client hosts and applications.

Below, use of `pgpro_stats` is assumed unless otherwise noted.

If you cannot use `pgpro_stats` for an observed database, but the [pg_stat_kcache](#) extension is available, `pgpro_pwr` can process `pg_stat_kcache` data, which also provides information about CPU resource usage of statements and filesystem load (*rusage*).

`pgpro_pwr` can obtain summary wait statistics from the [pg_wait_sampling](#) extension. When `pg_wait_sampling` is in use, `pgpro_pwr` will reset the wait sampling profile on every sample.

`pgpro_pwr` is based on cumulative statistics sampling. Each sample contains statistic increments for most active objects and queries since the time when the previous sample was taken, or more concisely, *since the previous sample*. This data is later used to generate reports.

`pgpro_pwr` provides functions to collect samples. Regular sampling allows building a report on the database workload in the past.

`pgpro_pwr` allows you to take explicit samples during batch processing, load testing, etc.

Any time a sample is taken, `pgpro_stats_statements_reset()` (see [pgpro_stats](#) for the function description) is called to ensure that statement statistics will not be lost when the statements count exceed `pgpro_stats.max` (see [Section F.43.7.1](#)). The report will also contain a section informing you of whether the count of captured statements in any sample reaches 90% of `pgpro_stats.max`.

`pgpro_pwr` installed on one Postgres Pro server can also collect statistics from other servers. This feature is useful for gathering workload statistics from hot standbys on the master server. To benefit from it, make sure that all server names and connection strings are specified and that the `pgpro_pwr` server can connect to all databases on all servers.

F.40.1. pgpro_pwr Architecture

The extension consists of the following parts:

- *Historical repository* is a storage for sampling data. The repository is a set of extension tables.

Note

Among the rest, `pgpro_pwr` tables store query texts, which can contain sensitive information. So, for security reasons, restrict access to the repository as appropriate.

- *Sample management engine* comprises functions used to [take samples](#) and maintain the repository by removing obsolete sample data.
- *Report engine* comprises functions for [generating reports](#) based on data from the historical repository.
- *Administrative functions* allow you to create and manage [servers](#) and [baselines](#).

F.40.2. Prerequisites

The prerequisites assume that `pgpro_pwr`, which is usually installed in a *target* cluster, i.e., the cluster that you will mainly track the workload for, the extension can also collect performance data from other clusters.

F.40.2.1. For the pgpro_pwr Database

The `pgpro_pwr` extension depends on [PL/pgSQL](#) and the [dblink](#) extension.

F.40.2.2. For the Target Server

The target server must allow connections to all databases from the server where `pgpro_pwr` is running. To connect to the target server, provide a connection string where a particular database on this server is specified. This database is of high importance for `pgpro_pwr` since the functionality of the [pgpro_stats](#) or [pg_stat_statements](#) extensions will be provided through this database. Note, however, that `pgpro_pwr` will also connect to all the other databases on this server.

Optionally, for completeness of gathered statistics:

- If statement statistics are needed in reports, [pgpro_stats](#) must be installed and configured in the aforementioned database. The following settings may affect the completeness and accuracy of gathered statistics:
 - `pgpro_stats.max`
Low setting of this parameter may cause some statement statistics to be wiped out before the sample is taken. A report will warn you if the value of `pgpro_stats.max` seems undersized.
 - `pgpro_stats.track`

Avoid changing the default value of 'top' (note that the value of 'all' will affect the accuracy of %Total fields for statements-related sections of a report).

- Set the parameters of the Postgres Pro's [Statistics Collector](#) as follows:

```
track_activities = on
track_counts = on
track_io_timing = on
track_wal_io_timing = on    # Since PostgreSQL 14
track_functions = all/pl
```

F.40.3. Installation and Setup

Note

pgpro_pwr creates a bunch of database objects, so installation in a dedicated schema is recommended.

Although the use of pgpro_pwr with superuser privileges does not have any issues, superuser privileges are not necessary. So you can choose one of the following setup procedures depending on your configuration and security requirements or customize them to meet your needs:

F.40.3.1. Simple Setup

Use this setup procedure when pgpro_pwr is to be installed on the target cluster to only track its workload as superuser.

Create a schema for the pgpro_pwr installation and create the extension:

```
CREATE SCHEMA profile;
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

F.40.3.2. Complex Setup

Use this setup procedure when you intend to use pgpro_pwr for tracking workload on one or more servers and need to follow the principle of least privilege.

F.40.3.2.1. In the Target Server Database

Create a user for pgpro_pwr on the target server:

```
CREATE USER pwr_collector PASSWORD 'collector_pwd';
```

Make sure this user has permissions to connect to any database in the target cluster (by default, it is true) and that pg_hba.conf permits such a connection from the pgpro_pwr database host. Also, grant pwr_collector with membership in the pg_read_all_stats role and the EXECUTE privilege on the following functions:

```
GRANT pg_read_all_stats TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgpro_stats_totals_reset(text,bigint) TO pwr_collector;
```

Also ensure the SELECT privilege on the pgpro_stats_archiver view:

```
GRANT SELECT ON pgpro_stats_archiver TO pwr_collector;
```

F.40.3.2.2. In the pgpro_pwr Database

Create an unprivileged user:

```
CREATE USER pwr_user;
```

This user will be the owner of the extension schema and will collect samples.

Create a schema for the `pgpro_pwr` installation:

```
CREATE SCHEMA profile AUTHORIZATION pwr_user;
```

Grant the `USAGE` privilege on the schema where the `dblink` extension resides:

```
GRANT USAGE ON SCHEMA public TO pwr_user;
```

Create the extension using `pwr_user` account:

```
\c - pwr_user
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

Define the connection parameters of the target server for `pgpro_pwr`. For example:

```
SELECT profile.create_server('target_server_name', 'host=192.168.1.100 dbname=postgres
port=5432');
```

The connection string provided will be used in the `dblink_connect()` call while executing the `take_sample()` function.

Note

Connection strings are stored in a `pgpro_pwr` table in clear-text form. Make sure no other database users can access tables of the `pgpro_pwr` extension.

F.40.3.3. Setting Up `pgpro_pwr` Roles

Up to three roles can be distinguished when `pgpro_pwr` is in operation:

- The *`pgpro_pwr` owner* role is the owner of the `pgpro_pwr` extension.
- The *collecting role* is used by `pgpro_pwr` to connect to databases and collect statistics.
- The *reporting role* is used to generate reports.

If all the actions with `pgpro_pwr` are performed by the superuser role `postgres`, you can skip most of the setup explained below.

F.40.3.3.1. The `pgpro_pwr` Owner

This role can be used to perform all actions related to `pgpro_pwr`. This role will have access to server connection strings, which may contain passwords. You should use this role to call the `take_sample()` function. The `dblink` extension is needed for this user.

Consider an example assuming each extension in its own schema:

```
\c postgres postgres
CREATE SCHEMA dblink;
CREATE EXTENSION dblink SCHEMA dblink;
CREATE USER pwr_usr with password 'pwr_pwd';
GRANT USAGE ON SCHEMA dblink TO pwr_usr;
CREATE SCHEMA profile AUTHORIZATION pwr_usr;
\c postgres pwr_usr
CREATE EXTENSION pgpro_pwr SCHEMA profile;
```

F.40.3.3.2. The Collecting Role

This role should be used by `pgpro_pwr` to connect to databases and collect statistics. Unprivileged users cannot open connections using `dblink` without a password, so you need to provide the password in the

connection string for each server. This role should have access to all supported statistics extensions. It should also be able to perform a reset of statistics extensions.

Consider an example. If you use `pgpro_stats` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgps;
CREATE EXTENSION pgpro_stats SCHEMA pgps;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgps TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgps.pgpro_stats_statements_reset TO pwr_collector;
```

If you use `pg_stat_statements` to collect statistics, set up the collecting role as follows:

```
\c postgres postgres
CREATE SCHEMA pgss;
CREATE SCHEMA pgsk;
CREATE SCHEMA pgws;
CREATE EXTENSION pg_stat_statements SCHEMA pgss;
CREATE EXTENSION pg_stat_kcache SCHEMA pgsk;
CREATE EXTENSION pg_wait_sampling SCHEMA pgws;
CREATE USER pwr_collector with password 'collector_pwd';
GRANT pg_read_all_stats TO pwr_collector;
GRANT USAGE ON SCHEMA pgss TO pwr_collector;
GRANT USAGE ON SCHEMA pgsk TO pwr_collector;
GRANT USAGE ON SCHEMA pgws TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgss.pg_stat_statements_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgsk.pg_stat_kcache_reset TO pwr_collector;
GRANT EXECUTE ON FUNCTION pgws.pg_wait_sampling_reset_profile TO pwr_collector;
```

Now you should set up a connection string pointing to the database with statistics extensions installed:

```
\c postgres pwr_usr
SELECT pgpro_pwr.set_server_connstr('local','dbname=postgres port=5432 host=localhost
user=pwr_collector password=collector_pwd');
```

Password authentication must be configured in the `pg_hba.conf` file for the `pwr_collector` user.

Obviously, the collecting role should be properly configured on all servers observed by `pgpro_pwr`.

Now you should be able to call `take_sample()` using the `pwr_usr` role:

```
\c postgres pwr_usr
SELECT * FROM take_sample();
```

And now it's time to configure the scheduler (in our example, the `crontab` command of the `postgres` user):

```
*/30 * * * *    psql -U pwr_usr -d postgres -c 'SELECT pgpro_pwr.take_sample()' > /dev/
null 2>&1
```

Note that you can use the Postgres Pro password file to store passwords.

F.40.3.3.3. The Reporting Role

Any user can build a `pgpro_pwr` report. The minimal privileges needed to generate `pgpro_pwr` reports are granted to the `public` role. However a full report, with query texts, is only available to the member of the `pg_read_all_stats` role. Anyway, the reporting role cannot access server connection strings, so it cannot get the passwords of servers.

F.40.3.4. Setting Extension Parameters

In `postgresql.conf`, you can define the following `pgpro_pwr` parameters:

`pgpro_pwr.max(integer)`

Number of top objects (statements, relations, etc.) to be reported in each sorted report table. This parameter affects the size of a sample.

The default value is 20.

`pgpro_pwr.max_sample_age(integer)`

Retention time of the sample, in days. Samples aged `pgpro_pwr.max_sample_age` days and older are automatically deleted on the next `take_sample()` call.

The default value is 7 days.

`pgpro_pwr.max_query_length(integer)`

Maximum query length allowed in reports. All queries in a report will be truncated to `pgpro_pwr.max_query_length` characters.

The default value is 20 000 characters.

`pgpro_pwr.track_sample_timings(boolean)`

Enables collecting detailed timing statistics of `pgpro_pwr`'s own sampling procedures. Set this parameter to diagnose why sampling functions run slowly. Collected timing statistics will be available in the `v_sample_timings` view.

The default value is `off`.

F.40.4. Managing Servers

Once installed, `pgpro_pwr` creates one enabled `local` server for the current cluster. If a server is *enabled*, `pgpro_pwr` includes it in sampling when no server is explicitly specified (see `take_sample()` for details). A server that is not enabled is referred to as *disabled*.

The default connection string for a local node contains only `dbname` and `port` parameters. The values of these parameters are taken from the connection used to create the extension. You can change the server connection string using the `set_server_connstr()` function when needed.

F.40.4.1. Server Management Functions

Use the following `pgpro_pwr` functions for server management:

```
create_server(server name, connstr text, enabled boolean DEFAULT TRUE, max_sample_age
integer DEFAULT NULL description text DEFAULT NULL)
```

Creates a server definition.

Arguments:

- `server` — server name. Must be unique.
- `connstr` — connection string. Must contain all the necessary settings to connect from `pgpro_pwr` server to the target server database.
- `enabled` — set to include the server in sampling by the `take_sample()` function without arguments.
- `max_sample_age` — retention time of the sample. Overrides the global `pgpro_pwr.max_sample_age` setting for this server.
- `description` — server description text, to be included in reports.

Here is an example of how to create a server definition:

```
SELECT profile.create_server('omega','host=192.168.1.100 dbname=postgres
port=5432');
```

```
drop_server(server name)
```

Drops a server and all its samples.

```
set_server_description(server name description text)
```

Sets a new server description.

```
enable_server(server name)
```

Includes a server in sampling by the `take_sample()` function without arguments.

```
disable_server(server name)
```

Excludes a server from sampling by the `take_sample()` function without arguments.

```
rename_server(server name, new_name name)
```

Renames a server.

```
set_server_max_sample_age(server name, max_sample_age integer)
```

Sets the retention period for a server (in days). To reset the server retention, set the value of `max_sample_age` to `NULL`.

```
set_server_db_exclude(server name, exclude_db name[])
```

Excludes a list of databases on a server from sampling. Use when `pgpro_pwr` is unable to connect to some databases in a cluster (for example, in Amazon RDS instances).

```
set_server_connstr(server name, server_connstr text)
```

Sets the connection string for a server.

```
show_servers()
```

Displays the list of configured servers.

F.40.5. Managing Samples

A *sample* contains the database workload statistics since the previous sample

F.40.5.1. Sampling Functions

The following `pgpro_pwr` functions relate to sampling:

```
take_sample()
```

```
take_sample(server name [, skip_sizes boolean])
```

Takes samples.

If the parameter is omitted, the function takes a sample on each enabled server. Servers are accessed for sampling sequentially, one by one. The function returns a table with the following columns:

- `server` — server name.
- `result` — result of taking the sample. Can be `OK` if the sample was taken successfully or contain the error trace text in case of exception.
- `elapsed` — time elapsed while the sample was taken.

If called with the parameter, the function takes a sample on the specified server even if this server is disabled. Use when you need different sampling frequencies on specific servers. Returns `0` on success.

Arguments:

- *server* — server name.
- *skip_sizes* — if omitted or set to null, the size-collection policy applies; if false, relation sizes are collected; if true, the collection of relation sizes is skipped.

```
take_sample_subset([sets_cnt integer, current_set integer])
```

Takes a sample on each server in a subset of servers. Use to take samples on servers in parallel if you have many enabled servers. Although PL/pgSQL does not support parallel execution, you can call this function in parallel sessions. This function returns the same type as `take_sample()`. If both parameters are omitted, the function behaves like the `take_sample()` function, i.e., it takes a sample on all enabled servers one by one.

Arguments:

- *sets_cnt* — number of subsets to divide all enabled servers into.
- *current_set* — number of the subset to collect samples for. Takes values from 0 through *sets_cnt* - 1. For the specified subset, samples are collected as usual, server by server.

If a reset of statistics since the previous sample was detected, `pgpro_pwr` treats corresponding absolute values as differentials; however, the accuracy will be affected anyway.

```
show_samples([server name,] [days integer])
```

Returns a table with information on server samples (local server is assumed if *server* is omitted) for the last *days* days (all existing samples are assumed if omitted). This table has the following columns:

- *sample* — sample identifier.
- *sample_time* — time when this sample was taken.
- *dbstats_reset* — NULL or the statistics reset timestamp of the `pg_stat_database` view if the statistics were reset since the previous sample.
- *clustats_reset* — NULL or the statistics reset timestamp of the `pg_stat_bgwriter` view if the statistics were reset since the previous sample.
- *archstats_reset* — NULL or the statistics reset timestamp of the `pg_stat_archiver` view if the statistics were reset since the previous sample.

Sampling functions also maintain the server repository by deleting obsolete samples and baselines according to the retention policy.

F.40.5.2. Taking Samples

To take samples for all enabled servers, call the `take_sample()` function. Usually, one or two samples per hour is sufficient. You can use a cron-like tool to schedule sampling. Here is an example for a 30-minute sampling period:

```
*/30 * * * *    psql -c 'SELECT profile.take_sample()' &> /dev/null
```

However, the results of such a call are not checked for errors. In a production environment, function results can be used for monitoring. This function returns OK for all servers with successfully taken samples and shows error text for failed servers:

```
SELECT * FROM take_sample();
```

server	result
elapsed	

+-----	
+-----	
ok_node	OK
00:00:00.48	

```
fail_node | could not establish connection
+| 00:00:00
          | SQL statement "SELECT dblink_connect('server_connection',server_connstr)"
+|
          | PL/pgSQL function take_sample(integer) line 69 at PERFORM
+|
          | PL/pgSQL function take_sample_subset(integer,integer) line 27 at
assignment+|
          | SQL function "take_sample" statement 1
+|
          | FATAL:  database "postgresno" does not exist
|
(2 rows)
```

F.40.5.3. Sample Retention Policy

You can define sample retention at the following levels:

1. *Global*

The value of the `pgpro_pwr.max_sample_age` parameter in the `postgresql.conf` file defines a common retention setting, which is effective if none of other related settings are defined.

2. *Server*

Specifying the `max_sample_age` parameter while creating a server or calling the `set_server_max_sample_age(server,max_sample_age)` function for an existing server defines the retention for the server. A server retention setting overrides `pgpro_pwr.max_sample_age` for a specific server.

3. *Baseline*

A [baseline](#) created overrides all the other retention periods for included samples.

F.40.6. Managing the Collection of Relation Sizes

It may take considerable time to collect sizes of all relations in a database by Postgres Pro relation-size functions. Besides, those functions require `AccessExclusiveLock` on a relation. However, it may be sufficient for you to collect relation sizes on a daily basis. `pgpro_pwr` allows you to skip collecting relation sizes by defining the *size-collection policy* for servers. The policy defines:

- A daily window when the collection of relation sizes is permitted.
- A minimum gap between two samples with relation sizes collected.

When the size-collection policy is defined, sampling functions collect relation sizes only when the sample is taken in the defined window and the previous sample with sizes is older than the gap. The following function defines this policy:

```
set_server_size_sampling(server name, window_start time with time zone DEFAULT NULL,
window_duration interval hour to second DEFAULT NULL, sample_interval interval day to
minute DEFAULT NULL)
```

Defines the size-collection policy for a server.

Arguments:

- `server` — server name.
- `window_start` — start time of the size-collection window.
- `window_duration` — duration of the size-collection window.
- `sample_interval` — minimum time gap between two samples with relation sizes collected.

Note

When you build a report between samples either of which lacks relation-size data, relation-growth sections will be based on `pg_class.relpages` data. However, you can expand the report interval bounds to the nearest samples with relation sizes collected using the `with_growth` parameter of [report generation functions](#); this makes the growth data more accurate.

Relation sizes are needed to calculate sequentially scanned volume for tables and explicit vacuum load for indexes.

Example:

```
SELECT set_server_size_sampling('local','23:00+03',interval '2 hour',interval '8
hour');
```

The `show_servers_size_sampling` function shows size collection policies for all servers:

```
postgres=# SELECT * FROM show_servers_size_sampling();
 server_name | window_start | window_end   | window_duration | sample_interval |
limited_collection
-----+-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----+-----
 local      | 23:00:00+03  | 01:00:00+03  | 02:00:00        | 08:00:00        | t
```

F.40.7. Managing Baselines

A *baseline* is a named sequence of samples that has its own retention setting. A baseline can be used as a sample interval in report generation functions. An undefined baseline retention means infinite retention. Use baselines to save information about the database workload for a certain time interval.

F.40.7.1. Baseline Management Functions

Use the following `pgpro_pwr` functions for baseline management:

```
create_baseline([server name,] baseline varchar(25), start_id integer, end_id integer [,
days integer])
create_baseline([server name,] baseline varchar(25), time_range tstzrange [, days in-
teger])
```

Creates a baseline.

Arguments:

- `server` — server name. `local` sever is assumed if omitted.
- `baseline` — baseline name. Must be unique for a server.
- `start_id` — identifier of the first sample in the baseline.
- `end_id` — identifier of the last sample in the baseline.
- `time_range` — time interval for the baseline. The baseline will include all samples for the minimal interval that covers `time_range`.
- `days` — baseline retention time, defined in integer days since `now()`. Omit or set to null for infinite retention.

```
drop_baseline([server name,] baseline varchar(25))
```

Drops a baseline. For the meaning and usage details of function arguments, see [create_baseline](#). Dropping a baseline does not mean dropping all its samples immediately. The baseline retention just no longer applies to them.

```
keep_baseline([server name,] baseline varchar(25) [, days integer])
```

Changes the retention of a baseline. For the meaning and usage details of function arguments, see [create_baseline](#). Omit the *baseline* parameter or pass null to it to change the retention of all existing baselines.

```
show_baselines([server name])
```

Displays existing baselines. Call `show_baselines` to get information about the baselines, such as names, sampling intervals and retention periods. `local` sever is assumed if the *server* parameter is omitted.

F.40.8. Data Export and Import

Collected samples can be exported from one instance of the `pgpro_pwr` extension and then loaded into another one. This feature helps you to move server data from one instance to another or to send collected data to your support team.

F.40.8.1. Data Export

The [export_data](#) function exports data to a regular table. You can use any method available to export this table from your database. For example, you can use the `\copy` meta-command of [psql](#) to obtain a single `csv` file:

```
postgres=# \copy (select * from export_data()) to 'export.csv'
```

F.40.8.2. Data Import

Since data can only be imported from a local table, first, load the data you exported. Using the `\copy` meta-command again:

```
postgres=# CREATE TABLE import (section_id bigint, row_data json);
CREATE TABLE
postgres=# \copy import from 'export.csv'
COPY 6437
```

Now you can import the data by providing the `import` table to the [import_data](#) function:

```
postgres=# SELECT * FROM import_data('import');
```

After successful import, you can drop the `import` table.

Note

If server data is imported for the first time, your local `pgpro_pwr` servers with matching names will cause a conflict during import. To avoid this, you can temporarily rename such servers or you can specify the server name prefix for import operations. However, during import of new data for already imported servers, they are matched by system identifiers, so feel free to rename imported servers. Also keep in mind that `pgpro_pwr` sets servers being imported to the *disabled* state for [take_sample\(\)](#) to bypass them.

F.40.8.3. Export and Import Functions

Use these functions to export or import data:

```
export_data([server name, [min_sample_id integer,] [max_sample_id integer,]] [, obfus-
cate_queries boolean])
```

Exports collected data.

Arguments:

- *server* — server name. All configured servers are assumed if omitted.
- *min_sample_id*, *max_sample_id* — sample identifiers to bound the export (inclusive). If *min_sample_id* is omitted or set to null, all samples until *max_sample_id* sample are exported; if *max_sample_id* is omitted or set to null, all samples since *min_sample_id* sample are exported.
- *obfuscate_queries* — if true, query texts are exported as MD5 hash.

```
import_data(data regclass [, server_name_prefix text])
```

Imports previously exported data. Returns the number of actually loaded rows in pgpro_pwr tables.

Arguments:

- *data* is the name of the table containing import data.
- *server_name_prefix* specifies the server name prefix for the import operation. It can be used to avoid name conflicts.

F.40.9. Report Generation Functions

pgpro_pwr reports are generated in HTML format by reporting functions. The following types of reports are available:

- *Regular reports* provide statistics on the workload for an interval.
- *Differential reports* provide statistics on the same objects for two intervals. Corresponding values are located next to each other, which makes it easy to compare the workloads.

Reporting functions take sample identifiers, baselines or time ranges to determine the intervals. For time ranges, these are the minimal intervals that cover the ranges.

F.40.9.1. Regular Reports

Use this function to generate regular reports:

```
get_report([server name,] start_id integer, end_id integer [, description text [,
with_growth boolean]])
get_report([server name,] time_range tstzrange [, description text [, with_growth
boolean]])
get_report([server name,] baseline varchar(25) [, description text [, with_growth
boolean]])
```

Generates a regular report.

Arguments:

- *server* — server name. local sever is assumed if omitted.
- *start_id* — identifier of the interval starting sample.
- *end_id* — identifier of the interval ending sample.
- *baseline* — baseline name.
- *time_range* — time range.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is false.

F.40.9.2. Differential Reports

Use this function to generate differential reports:

```
get_diffreport([server name,] start1_id integer, end1_id integer, start2_id integer,
end2_id integer [, description text [, with_growth boolean]])
get_diffreport([server name,] time_range1 tstzrange, time_range2 tstzrange [, description
text [, with_growth boolean]])
get_diffreport([server name,] baseline1 varchar(25), baseline2 varchar(25) [, description
text [, with_growth boolean]])
get_diffreport([server name,] baseline1 varchar(25), time_range2 tstzrange [, description
text [, with_growth boolean]])
get_diffreport([server name,] time_range1 tstzrange, baseline2 varchar(25) [, description
text [, with_growth boolean]])
get_diffreport([server name,] start1_id integer, end1_id integer, baseline2 varchar(25)
[, description text [, with_growth boolean]])
get_diffreport([server name,] baseline1 varchar(25), start2_id integer, end2_id integer
[, description text [, with_growth boolean]])
```

Generates a differential report for two intervals. The combinations of arguments provide possible ways to specify the two intervals.

Arguments:

- *server* — server name. local sever is assumed if omitted.
- *start1_id, end1_id* — identifiers of the starting and ending samples for the first interval.
- *start2_id, end2_id* — identifiers of the starting and ending samples for the second interval.
- *baseline1* — baseline name for the first interval.
- *baseline2* — baseline name for the second interval.
- *time_range1* — time range for the first interval.
- *time_range2* — time range for the second interval.
- *description* — short text to be included in the report as its description.
- *with_growth* — flag requesting interval expansion to the nearest bounds with data on relation growth available. The default value is *false*.

F.40.9.3. Report Generation Example

Generate a report for the *local* server and interval defined by samples:

```
psql -Aqtc "SELECT profile.get_report(480,482)" -o report_480_482.html
```

For any other server, provide its name:

```
psql -Aqtc "SELECT profile.get_report('omega',12,14)" -o report_omega_12_14.html
```

Generate a report using time ranges:

```
psql -Aqtc "SELECT profile.get_report(tstzrange('2020-05-13 11:51:35+03','2020-05-13
11:52:18+03'))" -o report_range.html
```

Generate a relative time-range report:

```
psql -Aqtc "SELECT profile.get_report(tstzrange(now() - interval '1 day',now()))" -o
report_last_day.html
```

F.40.10. pgpro_pwr Report Sections

Each *pgpro_pwr* report is divided into sections, described below. The number of top objects reported in each sorted report table is specified by the *pgpro_pwr.max* parameter.

Almost every item in the report can be accentuated by a single mouse click. The accentuated item will be instantly highlighted in all report sections, making it easy to find. The attributes identifying the item will appear in the bottom-right corner of the page. For example, if you click on a database name in the “Database statistics” report table, you can notice a small table with the database attributes in the bottom-right corner of the page.

When you scroll down the report, its table of contents will be available on the right side of the page. It can be hidden with a single mouse click on the “content” tag.

A substring-based filter is also available that helps limit the report contents to particular objects based on a substring. Specifically, substring-based filtering is applied to query texts.

F.40.10.1. Server statistics

Tables in this section of a `pgpro_pwr` report are described below.

The report table “Database statistics” provides per-database statistics for the report interval. The statistics are based on the `pg_stat_database` view. Table F.27 lists columns of this report table.

Table F.27. Database statistics

Column	Description	Field/Calculation
Database	Database name	<code>datname</code>
Commits	Number of committed transactions	<code>xact_commit</code>
Rollbacks	Number of rolled back transactions	<code>xact_rollback</code>
Deadlocks	Number of deadlocks detected	<code>deadlocks</code>
Checksum Failures	Number of data page checksum failures detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	<code>checksum_failures</code>
Checksums Last	Time at which the last data page checksum failure was detected in this database. This field is only shown if any checksum failures were detected in this database during the report interval.	<code>checksum_last_failure</code>
Hit%	Buffer cache hit ratio, i.e., percentage of pages fetched from buffers in all pages fetched	
Read	Number of disk blocks read in this database	<code>blks_read</code>
Hit	Number of times disk blocks were found already in the buffer cache	<code>blks_hit</code>
Ret	Number of returned tuples	<code>tup_returned</code>
Fet	Number of fetched tuples	<code>tup_fetched</code>
Ins	Number of inserted tuples	<code>tup_inserted</code>
Upd	Number of updated tuples	<code>tup_updated</code>
Del	Number of deleted tuples	<code>tup_deleted</code>

Column	Description	Field/Calculation
Temp Size	Total amount of data written to temporary files by queries in this database	temp_bytes
Temp Files	Number of temporary files created by queries in this database	temp_files
Size	Database size at the time of the last sample in the report interval	pg_database_size()
Growth	Database growth during the report interval	pg_database_size() increment between interval bounds

The report table “Cluster I/O statistics” provides I/O statistics by object types, backend types and contexts. This table is based on the `pg_stat_io` view of the [Cumulative Statistics System](#), available since Postgres Pro 16. [Table F.28](#) lists columns of this report table. Times are provided in seconds.

Table F.28. Cluster I/O statistics

Column	Description
Object	Target object of an I/O operation
Backend	Type of the backend that performed an I/O operation
Context	The context of an I/O operation
Reads Count	Number of read operations
Reads Bytes	Amount of data read
Reads Time	Time spent in read operations
Writes Count	Number of write operations
Writes Bytes	Amount of data written
Writes Time	Time spent in write operations
Writebacks Count	Number of blocks which the process requested the kernel write out to permanent storage
Writebacks Bytes	Amount of data requested for write out to permanent storage
Writebacks Time	Time spent in writeback operations, including the time spent queueing write-out requests and, potentially, the time spent to write out the dirty data
Extends Count	Number of relation extend operations
Extends Bytes	Amount of space used by extend operations
Extends Time	Time spent in extend operations
Hits	The number of times a desired block was found in a shared buffer
Evictions	Number of times a block has been written out from a shared or local buffer in order to make it available for another use
Reuses	The number of times an existing buffer in a size-limited ring buffer outside of shared buffers was reused as part of an I/O operation in the <code>bulkread</code> , <code>bulkwrite</code> , or <code>vacuum</code> contexts
Fsyncs Count	Number of fsync calls. These are only tracked in context <code>normal</code> .

Column	Description
Fsyncs Time	Time spent in fsync operations

The report table “Cluster SLRU statistics” provides access statistics on SLRU (simple least-recently-used) caches. This table is based on the `pg_stat_slru` view of the [Cumulative Statistics System](#). [Table F.29](#) lists columns of this report table. Times are provided in seconds.

Table F.29. Cluster SLRU statistics

Column	Description	Field/Calculation
Name	Name of the SLRU	<code>name</code>
Zeroed	Number of blocks zeroed during initializations	<code>blks_zeroed</code>
Hits	Number of times disk blocks were found already in the SLRU, so that a read was not necessary (this only includes hits in the SLRU, not the operating system's file system cache)	<code>blks_hit</code>
Reads	Number of disk blocks read for this SLRU	<code>blks_read</code>
%Hit	Number of disk block hits for this SLRU as the percentage of $\text{Reads} + \text{Hits}$	$\text{blks\_hit} * 100 / \text{blks\_read} + \text{blks\_hit}$
Writes	Number of disk blocks written for this SLRU	<code>blks_written</code>
Checked	Number of blocks checked for existence for this SLRU	<code>blks_exists</code>
Flushes	Number of flushes of dirty data for this SLRU	<code>flushes</code>
Truncates	Number of truncates for this SLRU	<code>truncates</code>

Table “Session statistics by database” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_database` view of the [Statistics Collector](#). [Table F.30](#) lists columns of this report table. Times are provided in seconds.

Table F.30. Session statistics by database

Column	Description	Field/Calculation
Database	Database name	
Timing Total	Time spent by database sessions in this database during the report interval (note that statistics are only updated when the state of a session changes, so if sessions have been idle for a long time, this idle time won't be included)	<code>session_time</code>
Timing Active	Time spent executing SQL statements in this database during the report interval (this corresponds to the states <code>active</code> and <code>fastpath</code> function call in <code>pg_stat_activity</code>)	<code>active_time</code>

Column	Description	Field/Calculation
Timing Idle (T)	Time spent idling while in a transaction in this database during the report interval (this corresponds to the states <code>idle in transaction</code> and <code>idle in transaction (aborted)</code> in <code>pg_stat_activity</code>)	<code>idle_in_transaction_time</code>
Sessions Established	Total number of sessions established to this database during the report interval	<code>sessions</code>
Sessions Abandoned	Number of database sessions to this database that were terminated because connection to the client was lost during the report interval	<code>sessions_abandoned</code>
Sessions Fatal	Number of database sessions to this database that were terminated by fatal errors during the report interval	<code>sessions_fatal</code>
Sessions Killed	Number of database sessions to this database that were terminated by operator intervention during the report interval	<code>sessions_killed</code>

In Postgres Pro databases of versions that include [pgpro_stats](#) version starting with 1.4, workload statistics of vacuum processes are available. The “Database vacuum statistics” report table provides per-database aggregated total vacuum statistics based on the `pgpro_stats_vacuum_tables` view. [Table F.31](#) lists columns of this report table. Times are provided in seconds.

Table F.31. Database vacuum statistics

Column	Description	Field/Calculation
Database	Database name	
Blocks fetched	Total number of database blocks fetched by vacuum operations	<code>total_blks_read</code> + <code>total_blks_hit</code>
%Total	Total number of database blocks fetched (read+hit) by vacuum operations as the percentage of all blocks fetched in the cluster	<code>Blocks fetched * 100 / Cluster fetched</code>
Blocks read	Total number of database blocks read by vacuum operations	<code>total_blks_read</code>
%Total	Total number of database blocks read by vacuum operations as the percentage of all blocks read in the cluster	<code>Blocks read * 100 / Cluster read</code>
VM Frozen	Total number of blocks marked all-frozen in the visibility map	<code>pages_frozen</code>
VM Visible	Total number of blocks marked all-visible in the visibility map	<code>pages_all_visible</code>
Tuples deleted	Total number of dead tuples vacuum operations deleted from tables of this database	<code>tuples_deleted</code>

Column	Description	Field/Calculation
Tuples left	Total number of dead tuples vacuum operations left in tables of this database due to their visibility in transactions	dead_tuples
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of tuples deleted from tables of this database in all dead tuples to be deleted from tables of this database.	$\text{tuples\_deleted} * 100 / (\text{tuples\_deleted} + \text{dead\_tuples})$
WAL size	Total amount of WAL bytes generated by vacuum operations performed on tables of this database	wal_bytes
Read I/O time	Time spent reading database blocks by vacuum operations performed on tables of this database	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on tables of this database	blk_write_time
%Total	Vacuum I/O time spent as the percentage of whole cluster I/O time	
Total vacuum time	Total time of vacuuming tables of this database	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on tables of this database	delay_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Interrupts	Number of times vacuum operations performed on tables of this database were interrupted on any errors	interrupts

If the [pgpro_stats](#) extension supporting invalidation statistics was available during the report interval, the "Invalidation messages by database" report table provides per-database aggregated total invalidation message statistics. [Table F.32](#) lists columns of this report table.

Table F.32. Invalidation messages by database

Column	Description	Field/Calculation
Database	Database name	
Invalidation messages sent	Total number of invalidation messages sent by backends in this database. Statistics are provided for corresponding message	Fields of <code>pgpro_stats_totals.inval_msgs</code>

Column	Description	Field/Calculation
	types of pgpro_stats_inval_msgs	
Cache resets	Total number of shared cache resets	pgpro_stats_totals.cache_resets

If the [pgpro_stats](#) extension was available during the report interval, the “Statement statistics by database” report table provides per-database aggregated total statistics for the `pgpro_stats_statements` view data. [Table F.33](#) lists columns of this report table. Times are provided in seconds.

Table F.33. Statement statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Read Time	Time spent reading blocks by all statements in the database	Sum of blk_read_time
Write Time	Time spent writing blocks by all statements in the database	Sum of blk_write_time
Trg Time	Time spent executing trigger functions by all statements in the database	
Shared Fetched	Total number of shared blocks fetched by all statements in the database	Sum of (shared_blks_read + shared_blks_hit)
Local Fetched	Total number of local blocks fetched by all statements in the database	Sum of (local_blks_read + local_blks_hit)
Shared Dirtied	Total number of shared blocks dirtied by all statements in the database	Sum of shared_blks_dirtied
Local Dirtied	Total number of local blocks dirtied by all statements in the database	Sum of local_blks_dirtied
Read Temp	Total number of temp blocks read by all statements in the database	Sum of temp_blks_read
Write Temp	Total number of temp blocks written by all statements in the database	Sum of temp_blks_written
Read Local	Total number of local blocks read by all statements in the database	Sum of local_blks_read
Write Local	Total number of local blocks written by all statements in the database	Sum of local_blks_written

Column	Description	Field/Calculation
Statements	Total number of captured statements	
WAL Size	Total amount of WAL generated by all statements in the database	Sum of wal_bytes

If the JIT-related statistics was available in the statement statistics extension during the report interval, the “JIT statistics by database” report table provides per-database aggregated total statistics of JIT executions. [Table F.34](#) lists columns of this report table. Times are provided in seconds.

Table F.34. JIT statistics by database

Column	Description	Field/Calculation
Database	Database name	
Calls	Number of times all statements in the database were executed	calls
Plan Time	Time spent planning all statements in the database	Sum of total_plan_time
Exec Time	Time spent executing all statements in the database	Sum of total_exec_time
Generation count	Total number of functions JIT-compiled by the statements	Sum of jit_functions
Generation time	Total time spent by the statements on generating JIT code	Sum of jit_generation_time
Inlining count	Number of times functions have been inlined	Sum of jit_inlining_count
Inlining time	Total time spent by statements on inlining functions	Sum of jit_inlining_time
Optimization count	Number of times statements have been optimized	Sum of jit_optimization_count
Optimization time	Total time spent by statements on optimizing	Sum of jit_optimization_time
Emission count	Number of times code has been emitted	Sum of jit_emission_count
Emission time	Total time spent by statements on emitting code	Sum of jit_emission_time

The report table “Cluster statistics” provides data from the `pg_stat_bgwriter` view. [Table F.35](#) lists rows of this report table. Times are provided in seconds.

Table F.35. Cluster statistics

Row	Description	Field/Calculation
Scheduled checkpoints	Number of scheduled checkpoints that have been performed	checkpoints_timed
Requested checkpoints	Number of requested checkpoints that have been performed	checkpoints_req
Checkpoint write time (s)	Total amount of time that has been spent in the portion of checkpoint processing where files are written to disk	checkpoint_write_time
Checkpoint sync time (s)	Total amount of time that has been spent in the portion of	checkpoint_sync_time

Row	Description	Field/Calculation
	checkpoint processing where files are synchronized to disk	
Checkpoint buffers written	Number of buffers written during checkpoints	buffers_checkpoint
Background buffers written	Number of buffers written by the background writer	buffers_clean
Backend buffers written	Number of buffers written directly by a backend	buffers_backend
Backend fsync count	Number of times a backend had to execute its own fsync call (normally the background writer handles those even when the backend does its own write)	buffers_backend_fsync
Bgwriter interrupts (too many buffers)	Number of times the background writer stopped a cleaning scan because it had written too many buffers	maxwritten_clean
Number of buffers allocated	Total number of buffers allocated	buffers_alloc
WAL generated	Total amount of WAL generated	pg_current_wal_lsn() value increment
Start LSN	Log sequence number at the start of a report interval	pg_current_wal_lsn() at the first sample of a report
End LSN	Log sequence number at the end of a report interval	pg_current_wal_lsn() at the last sample of a report
WAL generated by vacuum	Total amount of WAL generated by vacuum	Based on the wal_bytes field of the pgpro_stats_vacuum_databases view.
WAL segments archived	Total number of archived WAL segments	Based on pg_stat_archiver.archived_count
WAL segments archive failed	Total number of WAL segment archiver failures	Based on pg_stat_archiver.failed_count .
Archiver performance	Average archiver process performance per second	Based on the active_time field of the pgpro_stats_archiver view.
Archive command performance	Average archive_command performance per second	Based on the archive_command_time field of the pgpro_stats_archiver view.

Table “WAL statistics” is available in the report for Postgres Pro databases starting with version 14. This table is based on the `pg_stat_wal` view of the [Statistics Collector](#). [Table F.36](#) lists columns of this report table. Times are provided in seconds.

Table F.36. WAL statistics

Row	Description	Field/Calculation
WAL generated	Total amount of WAL generated during the report interval	wal_bytes
WAL per second	Average amount of WAL generated per second during the report interval	wal_bytes / report_duration

Row	Description	Field/Calculation
WAL records	Total number of WAL records generated during the report interval	wal_records
WAL FPI	Total number of WAL full page images generated during the report interval	wal_fpi
WAL buffers full	Number of times WAL data was written to disk because WAL buffers became full during the report interval	wal_buffers_full
WAL writes	Number of times WAL buffers were written out to disk via XLogWrite request during the report interval	wal_write
WAL writes per second	Average number of times WAL buffers were written out to disk via XLogWrite request per second during the report interval	wal_write / report_duration
WAL sync	Number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>fsync</code> is on and <code>wal_sync_method</code> is either <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero). See Section 29.4 for more information about the internal WAL function <code>issue_xlog_fsync</code> .	wal_sync
WAL syncs per second	Average number of times WAL files were synced to disk via <code>issue_xlog_fsync</code> request per second during the report interval	wal_sync / report_duration
WAL write time	Total amount of time spent writing WAL buffers to disk via XLogWrite request during the report interval (if <code>track_wal_io_timing</code> is enabled, otherwise zero; for more details, see Section 19.9). This includes the sync time when <code>wal_sync_method</code> is either <code>open_datasync</code> or <code>open_sync</code> .	wal_write_time
WAL write duty	WAL write time as the percentage of the report interval duration	wal_write_time * 100 / report_duration
WAL sync time	Total amount of time spent syncing WAL files to disk via <code>issue_xlog_fsync</code> request during the report interval (if <code>track_wal_io_timing</code> is enabled, <code>fsync</code> is on, and <code>wal_sync_method</code> is ei-	wal_sync_time

Row	Description	Field/Calculation
	ther <code>fdatasync</code> , <code>fsync</code> or <code>fsync_writethrough</code> , otherwise zero).	
WAL sync duty	WAL sync time as the percentage of the report interval duration	<code>wal_sync_time</code> * 100 / <code>report_duration</code>

The report table “Tablespace statistics” provides information on the sizes and growth of tablespaces. [Table F.37](#) lists columns of this report table.

Table F.37. Tablespace statistics

Column	Description	Field/Calculation
Tablespace	Tablespace name	<code>pg_tablespace .spcname</code>
Path	Tablespace path	<code>pg_tablespace_location()</code>
Size	Tablespace size at the time of the last sample in the report interval	<code>pg_tablespace_size()</code>
Growth	Tablespace growth during the report interval	<code>pg_tablespace_size()</code> increment between interval bounds

If the [pgpro_stats](#) extension was available during the report interval, the report table “Wait statistics by database” shows the total wait time by wait event type and database. [Table F.38](#) lists columns of this report table.

Table F.38. Wait statistics by database

Column	Description
Database	Database name
Wait event type	Type of event for which the backends were waiting. Asterisk means aggregation of all wait event types in the database.
Waited (s)	Time spent waiting in events of <code>Wait event type</code> , in seconds
%Total	Percentage of wait time spent in the database events of <code>Wait event type</code> in all wait time for the cluster

If the [pgpro_stats](#) extension was available during the report interval, the report table “Top wait events” shows top wait events in the cluster by wait time. [Table F.39](#) lists columns of this report table.

Table F.39. Top wait events

Column	Description
Database	Database name
Wait event type	The type of event for which the backends were waiting
Wait event	Wait event name for which the backends were waiting
Waited	Total wait time spent in <code>Wait event</code> of the database, in seconds
%Total	Percentage of wait time spent in <code>Wait event</code> of the database in all wait time in the cluster

F.40.10.2. Load distribution

This section of a `pgpro_pwr` report is based on the `pgpro_stats_totals` view of the `pgpro_stats` extension if it was available during the report interval. Each table in this section provides data for the report interval on load distribution for a certain kind of objects for which aggregated statistics are collected, such as databases, applications, hosts, or users. Each table contains one row for each resource (for example, total time or shared blocks written), where load distribution is shown in graphics, as a stacked bar chart for top objects by load of this resource. If the bar chart area that corresponds to an object is too narrow to include captions, point that area to get a hint with the caption, value and percentage. The report tables “Load distribution among heavily loaded databases”, “Load distribution among heavily loaded applications”, “Load distribution among heavily loaded hosts” and “Load distribution among heavily loaded users” show load distribution for respective objects. [Table F.40](#) lists rows of these report tables.

Table F.40. Load distribution

Row	Description	Calculation
Total time (sec.)	Total time spent in the planning and execution of statements	<code>total_plan_time</code> + <code>total_exec_time</code>
Executed count	Number of queries executed	<code>queries_executed</code>
I/O time (sec.)	Total time the statements spent reading or writing blocks (if track_io_timing is enabled, otherwise zero)	<code>blk_read_time</code> + <code>blk_write_time</code>
Blocks fetched	Total number of shared block cache hits and shared blocks read by the statements	<code>shared_blks_hit</code> + <code>shared_blks_read</code>
Shared blocks read	Total number of shared blocks read by the statements	<code>shared_blks_read</code>
Shared blocks dirtied	Total number of shared blocks dirtied by the statements	<code>shared_blks_dirtied</code>
Shared blocks written	Total number of shared blocks written by the statements	<code>shared_blks_written</code>
WAL generated	Total amount of WAL generated by the statements	<code>wal_bytes</code>
Temp and Local blocks written	Total number of temporary and local blocks written by the statements	<code>temp_blks_written</code> + <code>local_blks_written</code>
Temp and Local blocks read	Total number of temp and local blocks read by the statements	<code>temp_blks_read</code> + <code>local_blks_read</code>
Invalidation messages sent	Total number of all invalidation messages sent by backends in this database	<code>(pgpro_stats_totals .invalid_msgs).all</code>
Cache resets	Total number of shared cache resets	<code>pgpro_stats_totals .cache_resets</code>

F.40.10.3. SQL query statistics

This section of a `pgpro_pwr` report provides data for the report interval on top statements by several important statistics. The data is mainly captured from views of the one of `pgpro_stats` and `pg_stat_statements` extensions that was available during the report interval, with the precedence of `pgpro_stats`. Each statement can be highlighted in all SQL-related sections with a single mouse click on it. This click will also show a query text preview just under the query statistics row. The query text preview can be hidden with a second click on a query.

Tables of this report section are described below.

The report table “Top SQL by elapsed time” shows top statements by the sum of `total_plan_time` and `total_exec_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.41](#) lists columns of this report table. Times are provided in seconds.

Table F.41. Top SQL by elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
%Total	Percentage of elapsed time of this statement plan in the total elapsed time of all statements in the cluster	
Elapsed Time (s)	Total time spent in planning and execution of the statement plan	<code>total_plan_time</code> + <code>total_exec_time</code>
Plan Time (s)	Total time spent in planning of the statement	<code>total_plan_time</code>
Exec Time (s)	Total time spent in execution of the statement plan	<code>total_exec_time</code>
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	<code>jit_generation_time</code> + <code>jit_inlining_time</code> + <code>jit_optimization_time</code> + <code>jit_emission_time</code>
Read I/O time (s)	Total time the statement spent reading blocks	<code>blk_read_time</code>
Write I/O time (s)	Total time the statement spent writing blocks	<code>blk_write_time</code>
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	<code>rusage.user_time</code>
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	<code>rusage.system_time</code>
Plans	Number of times the statement was planned	<code>plans</code>
Executions	Number of executions of the statement plan	<code>calls</code>

The report table “Top SQL by planning time” shows top statements by the value of the `total_plan_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.42](#) lists columns of this report table.

Table F.42. Top SQL by planning time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Plan elapsed(s)	Total time spent in planning of the statement, in seconds	<code>total_plan_time</code>
%Elapsed	Percentage of <code>total_plan_time</code> in the sum of <code>total_plan_time</code> and <code>total_exec_time</code> of this statement plan	
Mean plan time	Mean time spent planning the statement, in milliseconds	<code>mean_plan_time</code>
Min plan time	Minimum time spent planning the statement, in milliseconds	<code>min_plan_time</code>
Max plan time	Maximum time spent planning the statement, in milliseconds	<code>max_plan_time</code>
StdErr plan time	Population standard deviation of time spent planning the statement, in milliseconds	<code>stddev_plan_time</code>
Plans	Number of times the statement was planned	<code>plans</code>
Executions	Number of executions of the statement plan	<code>calls</code>

The report table “Top SQL by execution time” shows top statements by the value of the `total_time` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.43](#) lists columns of this report table.

Table F.43. Top SQL by execution time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>

Column	Description	Field/Calculation
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Exec (s)	Total time spent executing the statement plan, in seconds	total_exec_time
%Elapsed	Percentage of total_exec_time of this statement plan in this statement elapsed time	
%Total	Percentage of total_exec_time of this statement plan in the total elapsed time of all statements in the cluster	
JIT Time (s)	Total time spent by JIT executing this statement plan, in seconds	jit_generation_time + jit_inlining_time + jit_optimization_time + jit_emission_time
Read I/O time (s)	Total time spent in reading pages while executing the statement plan, in seconds	blk_read_time
Write I/O time (s)	Total time spent in writing pages while executing the statement plan, in seconds	blk_write_time
Usr CPU time (s)	Time spent on CPU in the user space, in seconds	rusage.user_time
Sys CPU time (s)	Time spent on CPU in the system space, in seconds	rusage.system_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean execution time	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min execution time	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max execution time	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr execution time	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_exec_time
Executions	Number of executions of this statement plan	calls

The report table “Top SQL by executions” shows top statements by the value of the `calls` field of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.44](#) lists columns of this report table.

Table F.44. Top SQL by executions

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, data-	

Column	Description	Field/Calculation
	base ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Executions	Number of executions of the statement plan	calls
%Total	Percentage of calls of this statement plan in the total calls of all statements in the cluster	
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Mean (ms)	Mean time spent executing the statement plan, in milliseconds	mean_exec_time
Min (ms)	Minimum time spent executing the statement plan, in milliseconds	min_exec_time
Max (ms)	Maximum time spent executing the statement plan, in milliseconds	max_exec_time
StdErr (ms)	Population standard deviation of time spent executing the statement plan, in milliseconds	stddev_time
Elapsed(s)	Total time spent executing the statement plan, in seconds	total_exec_time

The report table “Top SQL by I/O wait time” shows top statements by read and write time, i.e., sum of values of `blk_read_time` and `blk_write_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.45](#) lists columns of this report table. Times are provided in seconds.

Table F.45. Top SQL by I/O wait time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid

Column	Description	Field/Calculation
User	Name of the user executing the statement	Derived from <code>userid</code>
IO(s)	Total time spent in reading and writing while executing this statement plan, i.e., I/O time	<code>blk_read_time</code> + <code>blk_write_time</code>
R(s)	Total time spent in reading while executing this statement plan	<code>blk_read_time</code>
W(s)	Total time spent in writing while executing this statement plan	<code>blk_write_time</code>
%Total	Percentage of I/O time of this statement plan in the total I/O time of all statements in the cluster	
Shr Reads	Total number of shared blocks read while executing the statement plan	<code>shared_blks_read</code>
Loc Reads	Total number of local blocks read while executing the statement plan	<code>local_blks_read</code>
Tmp Reads	Total number of temp blocks read while executing the statement plan	<code>temp_blks_read</code>
Shr Writes	Total number of shared blocks written while executing the statement plan	<code>shared_blks_written</code>
Loc Writes	Total number of local blocks written while executing the statement plan	<code>local_blks_written</code>
Tmp Writes	Total number of temp blocks written while executing the statement plan	<code>temp_blks_written</code>
Elapsed(s)	Total time spent in execution of the statement plan	<code>total_plan_time</code> + <code>total_exec_time</code>
Executions	Number of executions of the statement plan	<code>calls</code>

The report table “Top SQL by shared blocks fetched” shows top statements by the number of read and hit blocks, which helps to detect the most data-intensive statements. [Table F.46](#) lists columns of this report table.

Table F.46. Top SQL by shared blocks fetched

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	

Column	Description	Field/Calculation
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Blks fetched	Number of blocks retrieved while executing the statement plan	shared_blks_hit + shared_blks_read
%Total	Percentage of blocks fetched while executing the statement plan in all blocks fetched for all statements in the cluster	
Hits(%)	Percentage of blocks got from buffers in all blocks got	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by shared blocks read” shows top statements by the number of shared reads, which helps to detect the most read-intensive statements. [Table F.47](#) lists columns of this report table.

Table F.47. Top SQL by shared blocks read

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Reads	Number of shared blocks read while executing this statement plan	shared_blks_read
%Total	Percentage of shared reads for this statement plan in all shared reads of all statements in the cluster	

Column	Description	Field/Calculation
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Executions	Number of executions of the statement plan	<code>calls</code>

The report table “Top SQL by shared blocks dirtied” shows top statements by the number of shared dirtied buffers, which helps to detect statements that do most data changes in the cluster. [Table F.48](#) lists columns of this report table.

Table F.48. Top SQL by shared blocks dirtied

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Dirtied	Number of shared buffers dirtied while executing this statement plan	<code>shared_blks_dirtied</code>
%Total	Percentage of dirtied shared buffers for this statement plan in all dirtied shared buffers of all statements in the cluster	
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
WAL	Total amount of WAL bytes generated by the statement plan	<code>wal_bytes</code>
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>

Column	Description	Field/Calculation
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by shared blocks written” shows top statements by the number of blocks written. [Table F.49](#) lists columns of this report table.

Table F.49. Top SQL by shared blocks written

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Written	Number of blocks written while executing this statement plan	<code>shared_blks_written</code>
%Total	Percentage of blocks written by this statement plan in all written blocks in the cluster	Percentage of <code>shared_blks_written</code> in <code>(pg_stat_bgwriter.buffer_checkpoint + pg_stat_bgwriter.buffer_clean + pg_stat_bgwriter.buffer_backend)</code>
%BackendW	Percentage of blocks written by this statement plan in all blocks in the cluster written by backends	Percentage of <code>shared_blks_written</code> in <code>pg_stat_bgwriter.buffer_backend</code>
Hits (%)	Percentage of blocks got from buffers in all blocks got while executing this statement plan	
Elapsed (s)	Total time spent in execution of the statement plan, in seconds	<code>total_plan_time</code> + <code>total_exec_time</code>
Rows	Number of rows retrieved or affected by execution of the statement plan	<code>rows</code>
Executions	Number of executions of the statement plan	<code>calls</code>

The report table “Top SQL by WAL size” shows top statements by the amount of WAL generated. [Table F.50](#) lists columns of this report table.

Table F.50. Top SQL by WAL size

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, data-	

Column	Description	Field/Calculation
	base ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
WAL	Total amount of WAL bytes generated by the statement plan	wal_bytes
%Total	Percentage of WAL bytes generated by the statement plan in total WAL generated in the cluster	
Dirtied	Number of shared buffers dirtied while executing this statement plan	shared_blks_dirtied
WAL FPI	Total number of WAL full page images generated by the statement plan	wal_fpi
WAL records	Total number of WAL records generated by the statement plan	wal_records

The report table “Top SQL by temp usage” shows top statements by temporary I/O, which is calculated as the sum of `temp_blks_read`, `temp_blks_written`, `local_blks_read` and `local_blks_written` fields. [Table F.51](#) lists columns of this report table.

Table F.51. Top SQL by temp usage

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	planid
Database	Database name for the statement	Derived from dbid
User	Name of the user executing the statement	Derived from userid
Local fetched	Number of local blocks retrieved	<code>local_blks_hit</code> + <code>local_blks_read</code>
Hits(%)	Percentage of local blocks got from buffers in all local blocks got	

Column	Description	Field/Calculation
Write Local (blk)	Number of blocks written by this statement plan that are used in temporary tables	local_blks_written
Write Local %Total	Percentage of local_blks_written of this statement plan in the total of local_blks_written for all statements in the cluster	
Read Local (blk)	Number of blocks read by this statement plan that are used in temporary tables	local_blks_read
Read Local %Total	Percentage of local_blks_read of this statement plan in the total of local_blks_read for all statements in the cluster	
Write Temp (blk)	Number of temp blocks written by this statement plan	temp_blks_written
Write Temp %Total	Percentage of temp_blks_written of this statement plan in the total of temp_blks_written for all statements in the cluster	
Read Temp (blk)	Number of temp blocks read by this statement plan	temp_blks_read
Read Temp %Total	Percentage of temp_blks_read of this statement plan in the total of temp_blks_read for all statements in the cluster	
Elapsed(s)	Total time spent in execution of the statement plan, in seconds	total_plan_time + total_exec_time
Rows	Number of rows retrieved or affected by execution of the statement plan	rows
Executions	Number of executions of the statement plan	calls

The report table “Top SQL by invalidation messages sent” shows top statements by the number of invalidation messages sent. [Table F.52](#) lists columns of this report table.

Table F.52. Top SQL by invalidation messages sent

Column	Description	Field/Calculation
Query ID	Hex representation of queryid. The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	queryid
Plan ID	Internal hash code, computed from the tree of the statement plan	planid

Column	Description	Field/Calculation
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Invalidation messages sent	Total number of invalidation messages sent by backends executing this statement. Statistics are provided for corresponding message types of <code>pgpro_stats_inval_msgs</code>	fields of <code>pgpro_stats_statements.inval_msgs</code>

F.40.10.3.1. rusage statistics

This section is included in the report only if the `pgpro_stats` or `pg_stat_kcache` extension was available during the report interval.

The report table “Top SQL by system and user time” shows top statements by the sum of `user_time` and `system_time` fields of `pg_stat_kcache` or of the `pgpro_stats_totals` view. Table F.53 lists columns of this report table.

Table F.53. Top SQL by system and user time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Plan User (s)	User CPU time elapsed during planning, in seconds	<code>plan_user_time</code>
Exec User (s)	User CPU time elapsed during execution, in seconds	<code>exec_user_time</code>
User %Total	Percentage of <code>plan_user_time</code> + <code>exec_user_time</code> in the total user CPU time for all statements	
Plan System (s)	System CPU time elapsed during planning, in seconds	<code>plan_system_time</code>
Exec System (s)	System CPU time elapsed during execution, in seconds	<code>exec_system_time</code>
System %Total	Percentage of <code>plan_system_time</code> + <code>exec_system_time</code> in the total system CPU time for all statements	

The report table “Top SQL by reads/writes done by filesystem layer” shows top statements by the sum of `reads` and `writes` fields of `pg_stat_kcache`. Table F.54 lists columns of this report table.

Table F.54. Top SQL by reads/writes done by filesystem layer

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
Plan Read Bytes	Bytes read during planning	<code>plan_reads</code>
Exec Read Bytes	Bytes read during execution	<code>exec_reads</code>
Read Bytes %Total	Percentage of <code>plan_reads</code> + <code>exec_reads</code> in the total number of bytes read by the filesystem layer for all statements	
Plan Writes	Bytes written during planning	<code>plan_writes</code>
Exec Writes	Bytes written during execution	<code>exec_writes</code>
Write %Total	Percentage of <code>plan_writes</code> + <code>exec_writes</code> in the total number of bytes written by the filesystem layer for all statements	

F.40.10.4. SQL query wait statistics

If the `pgpro_stats` extension was available during the report interval, this section of the report will contain a table that is split into sections, each showing top statements by overall wait time or by wait time for a certain [wait event type](#). Table sections related to specific wait events follow in the descending order of the total wait time in wait events of this type. [Table F.55](#) lists columns of this report table. Times are provided in seconds.

Table F.55. SQL query wait statistics

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Hash of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>

Column	Description	Field/Calculation
Waited	Total wait time for all wait events of this statement plan	
%Total	Percentage of the total wait time of this statement plan in all the wait time in the cluster	
Details	Waits of this statement plan by wait types	

If the JIT-related statistics was available in the statement statistics extension during the report interval, the report table “Top SQL by JIT elapsed time” shows top statements by the sum of `jit_*_time` fields of the `pgpro_stats_statements` or `pg_stat_statements` view. [Table F.56](#) lists columns of this report table. Times are provided in seconds.

Table F.56. Top SQL by JIT elapsed time

Column	Description	Field/Calculation
Query ID	Hex representation of <code>queryid</code> . The hash of the query ID, database ID and user ID is in square brackets. The (N) mark will appear here for nested statements (such as statements invoked within top-level statements).	
Plan ID	Internal hash code, computed from the tree of the statement plan	<code>planid</code>
Database	Database name for the statement	Derived from <code>dbid</code>
User	Name of the user executing the statement	Derived from <code>userid</code>
JIT Time (s)	Total time spent by JIT executing this statement plan	<code>jit_generation_time</code> + <code>jit_inlining_time</code> + <code>jit_optimization_time</code> + <code>jit_emission_time</code>
Generation count	Total number of functions JIT-compiled by this statement	Sum of <code>jit_functions</code>
Generation time	Total time spent by this statement on generating JIT code	Sum of <code>jit_generation_time</code>
Inlining count	Number of times functions have been inlined	Sum of <code>jit_inlining_count</code>
Inlining time	Total time spent by this statement on inlining functions	Sum of <code>jit_inlining_time</code>
Optimization count	Number of times this statement has been optimized	Sum of <code>jit_optimization_count</code>
Optimization time	Total time spent by this statement on optimizing	Sum of <code>jit_optimization_time</code>
Emission count	Number of times code has been emitted	Sum of <code>jit_emission_count</code>
Emission time	Total time spent by this statement on emitting code	Sum of <code>jit_emission_time</code>
Plan Time (s)	Total time spent in planning of the statement	<code>total_plan_time</code>

Column	Description	Field/Calculation
Exec Time (s)	Total time spent in execution of the statement plan	total_exec_time
Read I/O time (s)	Total time the statement spent reading blocks	blk_read_time
Write I/O time (s)	Total time the statement spent writing blocks	blk_write_time

F.40.10.5. Complete list of SQL texts

The “Complete list of SQL texts” section of the report contains a table that provides query and plan texts for all statements mentioned in the report. Use an appropriate `Query ID/Plan ID` link in any statistics table to see the corresponding query/plan text. [Table F.57](#) lists columns of this report table.

Table F.57. Complete list of SQL texts

Column	Description
ID	Hex representation of the query or plan identifier
Query/Plan Text	Text of the query or statement plan

F.40.10.6. Schema object statistics

Tables in this section of the report show top database objects by statistics from the Postgres Pro's [Statistics Collector](#) views.

The report table “Top tables by estimated sequentially scanned volume” shows top tables by estimated volume read by sequential scans. This can help you find database tables that possibly lack some index. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. The data is based on the `pg_stat_all_tables` view. [Table F.58](#) lists columns of this report table.

Table F.58. Top tables by estimated sequentially scanned volume

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
~SeqBytes	Estimated volume read by sequential scans	Sum of (<code>pg_relation_size()</code> * <code>seq_scan</code>)
SeqScan	Number of sequential scans performed on the table	<code>seq_scan</code>
IxScan	Number of index scans initiated on the table	<code>idx_scan</code>
IxFet	Number of live rows fetched by index scans	<code>idx_tup_fetch</code>
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

In the report table “Top tables by blocks fetched”, blocks fetched include blocks being processed from disk (read) and from shared buffers (hit). This report table shows top database tables by the sum of blocks

fetches for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive processing of blocks. The data is based on the [pg_statio_all_tables](#) view. [Table F.59](#) lists columns of this report table.

Table F.59. Top tables by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks fetched for the table's heap	heap_blks_read + heap_blks_hit
Heap Blks %Total	Percentage of blocks fetched for the table's heap in all blocks fetched in the cluster	
Ix Blks	Number of blocks fetched for table's indexes	idx_blks_read + idx_blks_hit
Ix Blks %Total	Percentage of blocks fetched for table's indexes in all blocks fetched in the cluster	
TOAST Blks	Number of blocks fetched for the table's TOAST table	toast_blks_read + toast_blks_hit
TOAST Blks %Total	Percentage of blocks fetched for the table's TOAST table in all blocks fetched in the cluster	
TOAST-Ix Blks	Number of blocks fetched for the table's TOAST index	tidx_blks_read + tidx_blks_hit
TOAST-Ix Blks %Total	Percentage of blocks fetched for the table's TOAST index in all blocks fetched in the cluster	

The report table "Top tables by blocks read" shows top database tables by the number of blocks read for the table's heap, indexes, TOAST table (if any) and TOAST table index (if any). This can help you focus on tables with excessive block readings. The data is based on the [pg_statio_all_tables](#) view. [Table F.60](#) lists columns of this report table.

Table F.60. Top tables by blocks read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Heap Blks	Number of blocks read for the table's heap	heap_blks_read
Heap Blks %Total	Percentage of blocks read from the table's heap in all blocks read in the cluster	

Column	Description	Field/Calculation
Ix Blks	Number of blocks read from table's indexes	idx_blks_read
Ix Blks %Total	Percentage of blocks read from table's indexes in all blocks read in the cluster	
TOAST Blks	Number of blocks read from the table's TOAST table	toast_blks_read
TOAST Blks %Total	Percentage of blocks read from the table's TOAST table in all blocks read in the cluster	
TOAST-Ix Blks	Number of blocks read from the table's TOAST index	tidx_blks_read
TOAST-Ix Blks %Total	Percentage of blocks read from the table's TOAST index in all blocks read in the cluster	
Hit (%)	Percentage of table, index, TOAST and TOAST index blocks got from buffers for this table in all blocks got for this table from either file system or buffers	

The report table “Top DML tables” shows top tables by the number of DML-affected rows, i.e., by the sum of `n_tup_ins`, `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the `pg_stat_all_tables` view. [Table F.61](#) lists columns of this report table.

Table F.61. Top DML tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>
SeqScan	Number of sequential scans performed on the table	<code>seq_scan</code>
SeqFet	Number of live rows fetched by sequential scans	<code>seq_tup_read</code>
IxScan	Number of index scans initiated on this table	<code>idx_scan</code>
IxFet	Number of live rows fetched by index scans	<code>idx_tup_fetch</code>

The report table “Top tables by updated/deleted tuples” shows top tables by tuples modified by UPDATE/DELETE operations, i.e., by the sum of `n_tup_upd` and `n_tup_del` (including TOAST tables). The data is based on the `pg_stat_all_tables` view. [Table F.62](#) lists columns of this report table.

Table F.62. Top tables by updated/deleted tuples

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Upd	Number of rows updated, including HOT	n_tup_upd
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd
Del	Number of rows deleted	n_tup_del
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Analyze	Number of times this table was manually analyzed	analyze_count
AutoAnalyze	Number of times this table was analyzed by the autovacuum daemon	autoanalyze_count

The report table “Top tables by removed all-visible marks” shows top tables by the number of times that the all-visible mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table F.63](#) lists columns of this report table.

Table F.63. Top tables by removed all-visible marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Visible marks cleared	Number of times that the all-visible mark was removed from the relation visibility map	rev_all_visible_pages
All-Visible marks set	Number of times that the all-visible mark was set in the relation visibility map	pages_all_visible
All-Visible marks %Set	Percentage of the number of times that the all-visible mark was set in the number of times that it was set or removed	$\text{pages\_all\_visible} * 100\% / (\text{rev\_all\_visible\_pages} + \text{pages\_all\_visible})$
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count

Column	Description	Field/Calculation
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by removed all-frozen marks” shows top tables by the number of times that the all-frozen mark was removed from the visibility map by any backend. This report section is only shown when corresponding statistics are available. [Table F.64](#) lists columns of this report table.

Table F.64. Top tables by removed all-frozen marks

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
All-Frozen marks cleared	Number of times that the all-frozen mark was removed from the relation visibility map	rev_all_frozen_pages
All-Frozen marks set	Number of times that the all-frozen mark was set in the relation visibility map	pages_frozen
All-Frozen marks %Set	Percentage of the number of times that the all-frozen mark was set in the number of times that it was set or removed	$\text{pages\_frozen} * 100\% / (\text{rev\_all\_frozen\_pages} + \text{pages\_frozen})$
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
AutoVacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by new-page updated tuples” shows top tables by the number of rows updated where the successor version goes onto a *new* heap page, leaving behind an original version with a `t_ctid` field that points to a different heap page. These are always non-HOT updates. [Table F.65](#) lists columns of this report table.

Table F.65. Top tables by new-page updated tuples

Column	Description
DB	Database name for the table
Tablespace	Name of the tablespace where the table is located
Schema	Schema name for the table
Table	Table name
NP Upd	Number of rows updated to a new heap page
%Upd	Number of new-page updated rows as the percentage of all rows updated
Upd	Number of rows updated, including HOT
Upd (HOT)	Number of rows HOT updated (i.e., with no separate index update required)

The report table “Top growing tables” shows top tables by growth. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.66 lists columns of this report table.

Table F.66. Top growing tables

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Size	Table size at the time of the last sample in the report interval	<code>pg_table_size()</code> - <code>pg_relation_size(toast)</code>
Growth	Table growth	
Ins	Number of rows inserted	<code>n_tup_ins</code>
Upd	Number of rows updated, including HOT	<code>n_tup_upd</code>
Del	Number of rows deleted	<code>n_tup_del</code>
Upd (HOT)	Number of rows HOT updated	<code>n_tup_hot_upd</code>

In the report table “Top indexes by blocks fetched”, blocks fetched include index blocks processed from disk (read) and from shared buffers (hit). The data is based on the `pg_statio_all_indexes` view. Table F.67 lists columns of this report table.

Table F.67. Top indexes by blocks fetched

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	<code>idx_scan</code>
Blks	Number of blocks fetched for this index	<code>idx_blks_read</code> + <code>idx_blks_hit</code>
%Total	Percentage of blocks fetched for this index in all blocks fetched in the cluster	

The report table “Top indexes by blocks read” is also based on the `pg_statio_all_indexes` and `pgstattat_all_indexes` views. Table F.68 lists columns of this report table.

Table F.68. Top indexes by blocks read

Column	Description	Field/Calculation
DB	Database name for the index	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Scans	Number of index scans initiated on this index	idx_scan
Blk Reads	Number of disk blocks read from this index	idx_blks_read
%Total	Percentage of disk blocks read from this index in all disk blocks read in the cluster	
Hits(%)	Percentage of index blocks got from buffers in all index blocks got for this index	

The report table “Top growing indexes” shows top indexes by growth. The table uses data from the `pg_stat_all_tables` and `pg_stat_all_indexes` views. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.69 lists columns of this report table.

Table F.69. Top growing indexes

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	<code>pg_relation_size()</code>
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	<code>n_tup_ins</code>
Table Upd	Number of rows updated in the underlying table, without HOT	<code>n_tup_upd - n_tup_hot_upd</code>
Table Del	Number of rows deleted from the underlying table	<code>n_tup_del</code>

The report table “Unused indexes” shows top non-scanned indexes (during the report interval) by DML operations on underlying tables that caused index support. Constraint indexes are not counted. The table uses data from the `pg_stat_all_tables` view. Table F.70 lists columns of this report table.

Table F.70. Unused indexes

Column	Description	Field/Calculation
DB	Database name for the index	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
Index Size	Index size at the time of the last sample in the report interval	pg_relation_size()
Index Growth	Index growth during the report interval	
Table Ins	Number of rows inserted into the underlying table	n_tup_ins
Table Upd	Number of rows updated in the underlying table, without HOT	n_tup_upd - n_tup_hot_upd
Table Del	Number of rows deleted from the underlying table	n_tup_del

F.40.10.7. User function statistics

Tables in this section of the report show top functions in the cluster by statistics from the `pg_stat_user_functions` view. Times in the tables are provided in seconds.

The report table “Top functions by total time” shows top functions by the total time elapsed. The report table “Top functions by executions” shows top functions by the number of executions. The report table “Top trigger functions by total time” shows top trigger functions by the total time elapsed. [Table F.71](#) lists columns of these report tables.

Table F.71. User function statistics

Column	Description	Field/Calculation
DB	Database name for the function	
Schema	Schema name for the function	
Function	Function name	
Executions	Number of times this function has been called	calls
Total Time (s)	Total time spent in this function and all other functions called by it	total_time
Self Time (s)	Total time spent in this function itself, not including other functions called by it	self_time
Mean Time (s)	Mean time of a single function execution	total_time /calls
Mean self Time (s)	Mean self time of a single function execution	self_time /calls

F.40.10.8. Vacuum-related statistics

The report table “Top tables by vacuum time spent” is available if `pgpro_stats` can provide extended vacuum statistics. This table shows top tables by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.72](#) lists columns of this report table.

Table F.72. Top tables by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Total vacuum time	Total time of vacuuming this table	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this table	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this table	blk_write_time
User CPU time	User CPU time of vacuuming tables of this database	user_time
System CPU time	System CPU time of vacuuming tables of this database	system_time
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by vacuum time spent” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by total time spent vacuuming them. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.73](#) lists columns of this report table.

Table F.73. Top indexes by vacuum time spent

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	

Column	Description	Field/Calculation
Index	Index name	
Total vacuum time	Total time of vacuuming this index	total_time
Delay vacuum time	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index	delay_time
Read I/O time	Time spent reading database blocks by vacuum operations performed on this index	blk_read_time
Write I/O time	Time spent writing database blocks by vacuum operations performed on this index	blk_write_time
User CPU time	User CPU time of vacuuming this index	user_time
System CPU time	System CPU time of vacuuming this index	system_time
Vacuum count	Number of times the underlying table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times the underlying table has been vacuumed by the autovacuum daemon	autovacuum_count
Total fetched	Total number of database blocks fetched by vacuum operations performed on the underlying table	total_blks_read + total_blks_hit
Index fetched	Total number of blocks fetched from this index by vacuum operations performed on it	rel_blks_read + rel_blks_hit

The report table “Top tables by blocks vacuum fetched” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks fetched vacuuming these tables. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.74](#) lists columns of this report table.

Table F.74. Top tables by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this table	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched in the cluster	

Column	Description	Field/Calculation
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
Heap fetched	Total number of blocks fetched from this table by vacuum operations performed on it	rel_blks_read + rel_blks_hit
%Rel	Total number of table blocks fetched by vacuum operations performed on this table as the percentage of all blocks fetched from this table	
Heap read	Total number of blocks read from this table by vacuum operations performed on it	rel_blks_read
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum fetched” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by blocks fetched vacuuming underlying tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.75](#) lists columns of this report table.

Table F.75. Top indexes by blocks vacuum fetched

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB fetched	Total number of database blocks fetched by vacuum operations performed on this index	total_blks_read + total_blks_hit
%Total	Total number of database blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched in the cluster	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read

Column	Description	Field/Calculation
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
Idx fetched	Total number of blocks fetched from this index by vacuum operations on it	rel_blks_read + rel_blks_hit
%Idx	Total number of index blocks fetched by vacuum operations performed on this index as the percentage of all blocks fetched from this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	

The report table “Top tables by blocks vacuum read” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by blocks read vacuuming these tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.76](#) lists columns of this report table.

Table F.76. Top tables by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
DB read	Total number of database blocks read by vacuum operations performed on this table	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this table as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this table as the percentage of all blocks fetched by vacuum operations performed on this table	
Heap read	Total number of database blocks vacuum operations read from this table	rel_blks_read

Column	Description	Field/Calculation
%Rel	Total number of table blocks read by vacuum operations performed on this table as the percentage of all blocks read from this table	
%Hit	Total number of table blocks found in shared buffers by vacuum operations performed on this table as the percentage of table blocks fetched by vacuum operations performed on this table	
Scanned	Number of pages examined by vacuum operations performed on this table	pages_scanned

The report table “Top indexes by blocks vacuum read” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top indexes by blocks read vacuuming underlying tables. The data is based on the `pgpro_stats_vacuum_indexes` view. [Table F.77](#) lists columns of this report table.

Table F.77. Top indexes by blocks vacuum read

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Index	Index name	
DB read	Total number of database blocks read by vacuum operations performed on this index	total_blks_read
%Total	Total number of database blocks read by vacuum operations performed on this index as the percentage of all blocks read in the cluster	
%Hit	Total number of database blocks found in shared buffers by vacuum operations performed on this index as the percentage of all database blocks fetched by vacuum operations performed on this index	
Idx read	Total number of blocks read from this index by vacuum operations performed on it	rel_blks_read
%Idx	Total number of index blocks read by vacuum operations performed on this index as the percentage of all blocks read from this index	

Column	Description	Field/Calculation
%Hit	Total number of index blocks found in shared buffers by vacuum operations performed on this index as the percentage of index blocks fetched by vacuum operations performed on this index	

The report table “Top tables by dead tuples vacuum left” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by the number of dead tuples left by vacuum due to their visibility in transactions. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.78](#) lists columns of this report table.

Table F.78. Top tables by dead tuples vacuum left

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Dead tuples left	Total number of dead tuples vacuum operations left in this table due to their visibility in transactions	<code>dead_tuples</code>
Dead tuples deleted	Total number of dead tuples vacuum operations deleted from this table	<code>tuples_deleted</code>
%Eff	Vacuum efficiency in terms of deleted tuples. This is the percentage of dead tuples deleted from this table in all dead tuples to be deleted from this table.	$\text{tuples\_deleted} * 100 / (\text{tuples\_deleted} + \text{dead\_tuples})$
Tuples del	Number of rows deleted	<code>pg_stat_all_tables .n_tup_del</code>
Tuples upd	Number of rows updated (includes HOT updated rows)	<code>pg_stat_all_tables .n_tup_upd</code>
Vacuum	Number of times this table has been manually vacuumed (not counting <code>VACUUM FULL</code>)	<code>vacuum_count</code>
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	<code>autovacuum_count</code>

The report table “Top tables by WAL size generated by vacuum” is available if [pgpro_stats](#) can provide extended vacuum statistics. This table shows top tables by the amount of WAL generated by vacuum operations performed on them. The data is based on the `pgpro_stats_vacuum_tables` view. [Table F.79](#) lists columns of this report table.

Table F.79. Top tables by WAL size generated by vacuum

Column	Description	Field/Calculation
DB	Database name for the table	

Column	Description	Field/Calculation
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
WAL size	Total amount of WAL bytes generated by vacuum operations performed on this table	wal_bytes
%Total	Total amount of WAL bytes generated by vacuum operations performed on this table as the percentage of all WAL generated in the cluster	
WAL FPI	Total number of WAL full page images generated by vacuum operations performed on this table	wal_fpi
Scanned blocks	Number of pages examined by vacuum operations performed on this table	pages_scanned
Dirtied blocks	Number of database blocks dirtied by vacuum operations performed on this table	total_blks_dirtied
Removed blocks	Number of pages removed by vacuum operations performed on this table	pages_removed
Vacuum	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count

The report table “Top tables by vacuum operations” shows top tables by the number of vacuum operations performed (`vacuum_count + autovacuum_count`). The data is based on the [pg_stat_all_tables](#) view. [Table F.80](#) lists columns of this report table.

Table F.80. Top tables by vacuum operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
Ins	Number of rows inserted	n_tup_ins

Column	Description	Field/Calculation
Upd	Number of rows updated (includes HOT updated rows)	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top tables by analyze operations” shows top tables by the number of analyze operations performed (`analyze_count + autoanalyze_count`). The data is based on the `pg_stat_all_tables` view. Table F.81 lists columns of this report table.

Table F.81. Top tables by analyze operations

Column	Description	Field/Calculation
DB	Database name for the table	
Tablespace	Name of the tablespace where the table is located	
Schema	Schema name for the table	
Table	Table name	
Analyze count	Number of times this table has been manually analyzed	analyze_count
Autoanalyze count	Number of times this table has been analyzed by the autovacuum daemon	autoanalyze_count
Ins	Number of rows inserted	n_tup_ins
Upd	Number of rows updated, including HOT	n_tup_upd
Del	Number of rows deleted	n_tup_del
Upd (HOT)	Number of rows HOT updated	n_tup_hot_upd

The report table “Top indexes by estimated vacuum load” shows top indexes by estimated implicit vacuum load. This load is calculated as the number of vacuum operations performed on the underlying table multiplied by the index size. The data is based on the `pg_stat_all_indexes` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.82 lists columns of this report table.

Table F.82. Top indexes by estimated vacuum load

Column	Description	Field/Calculation
DB	Database name for the index	
Tablespace	Name of the tablespace where the index is located	
Schema	Schema name for the underlying table	
Table	Underlying table name	
Index	Index name	
~Vacuum bytes	Vacuum load estimation	(vacuum_count + autovacuum_count) * index_size
Vacuum count	Number of times this table has been manually vacuumed (not counting VACUUM FULL)	vacuum_count

Column	Description	Field/Calculation
Autovacuum count	Number of times this table has been vacuumed by the autovacuum daemon	autovacuum_count
IX size	Average index size during the report interval	
Relsize	Average relation size during the report interval	

The report table “Top tables by dead tuples ratio” shows top tables larger than 5 MB by the ratio of dead tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.83 lists columns of this report table.

Table F.83. Top tables by dead tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
%Dead	Percentage of dead rows in all table rows	
Last AV	Last time at which this table was vacuumed by the autovacuum daemon	last_autovacuum
Size	Table size	pg_table_size() - pg_relation_size(toast)

The report table “Top tables by modified tuples ratio” shows top tables larger than 5 MB by the ratio of modified tuples. Statistics are valid for the last sample in the report interval. The data is based on the `pg_stat_all_tables` view. When there are no relation sizes collected with `pg_relation_size()`, relation-size estimates are based on the `pg_class.relpages` field. Since such values are less accurate, they are shown in square brackets. Table F.84 lists columns of this report table.

Table F.84. Top tables by modified tuples ratio

Column	Description	Field/Calculation
DB	Database name for the table	
Schema	Schema name for the table	
Table	Table name	
Live	Estimated number of live rows	n_live_tup
Dead	Estimated number of dead rows	n_dead_tup
Mod	Estimated number of rows modified since this table was last analyzed	n_mod_since_analyze
%Mod	Percentage of modified rows in all table rows	

Column	Description	Field/Calculation
Last AA	Last time at which this table was analyzed by the autovacuum daemon	last_autoanalyze
Size	Table size	pg_table_size() - pg_relation_size(toast)

F.40.10.9. Cluster settings during the report interval

This section of the report contains a table with Postgres Pro GUC parameters, values of functions `version()`, `pg_postmaster_start_time()`, `pg_conf_load_time()` and the `system_identifier` field of the `pg_control_system()` function during the report interval. The data in the table is grouped under `Defined settings` and `Default settings`. [Table F.85](#) lists columns of this report table.

Table F.85. Cluster settings during the report interval

Column	Description
Setting	Name of the parameter
reset_val	<code>reset_val</code> field of the <code>pg_settings</code> view. Settings changed during the report interval are shown in bold font.
Unit	Unit of the setting
Source	Configuration file where this setting is defined, semicolon, line number
Notes	Timestamp of the sample where this value was first observed

F.40.11. pgpro_pwr Diagnostic Tools

`pgpro_pwr` provides self-diagnostic tools.

F.40.11.1. Collecting Detailed Timing Statistics for Sampling Procedures

`pgpro_pwr` collects detailed timing statistics of taking samples when the `pgpro_pwr.track_sample_timings` parameter is on. You can get the results from the `v_sample_timings` view. [Table F.86](#) lists columns of this view.

Table F.86. v_sample_timings View

Column	Description
server_name	Name of the server
sample_id	Sample identifier
sample_time	Time when the sample was taken
sampling_event	Sampling stage. See Table F.87 for descriptions of sampling stages.
time_spent	Time spent in the event

Table F.87. sampling_event Description

Event	Description
total	Taking the sample (all stages)
connect	Making dblink connection to the server
get server environment	Getting server GUC parameters, available extensions, etc.

Event	Description
collect database stats	Querying the <code>pg_stat_database</code> view for statistics on databases
calculate database stats	Calculating differential statistics on databases since the previous sample
collect tablespace stats	Querying the <code>pg_tablespace</code> view for statistics on tablespaces
collect statement stats	Collecting statistics on statements using the <code>pg-pro_stats</code> and <code>pg_stat_kcache</code> extensions
query pg_stat_bgwriter	Collecting cluster statistics using the <code>pg_stat_bgwriter</code> view
query pg_stat_archiver	Collecting cluster statistics using the <code>pg_stat_archiver</code> view
collect object stats	Collecting statistics on database objects. Includes events from Table F.88.
maintain repository	Executing support routines
calculate tablespace stats	Calculating differential statistics on tablespaces
calculate object stats	Calculating differential statistics on database objects. Includes events from Table F.89.
calculate cluster stats	Calculating cluster differential statistics
calculate archiver stats	Calculating archiver differential statistics
delete obsolete samples	Deleting obsolete baselines and samples

Table F.88. Events of Collecting Statistics on Database Objects

Event	Description
<code>db:dbname collect tables stats</code>	Collecting statistics on tables for the <i>dbname</i> database
<code>db:dbname collect indexes stats</code>	Collecting statistics on indexes for the <i>dbname</i> database
<code>db:dbname collect functions stats</code>	Collecting statistics on functions for the <i>dbname</i> database

Table F.89. Events of Calculating Differences of Statistics on Database Objects

Event	Description
calculate tables stats	Calculating differential statistics on tables of all databases
calculate indexes stats	Calculating differential statistics on indexes of all databases
calculate functions stats	Calculating differential statistics on functions of all databases

F.40.12. Important Notes

When using the `pgpro_pwr` extension, be aware of the following:

- Postgres Pro collects execution statistics *after* the execution is complete. If a single execution of a statement lasts for several samples, it will only affect statistics of the last sample (in which the execution completed). Besides, statistics on statements that are still running are unavailable. Maintenance processes, such as vacuum and checkpoint, will update the statistics only on completion.

- Resetting any Postgres Pro statistics may affect the accuracy of the next sample.
- Exclusive locks on relations conflict with calculation of the relation size. If the `take_sample()` function is unable to acquire a lock for a short period of time (3 seconds), it will fail and no sample will be generated.

F.41. pg_prewarm

The `pg_prewarm` module provides a convenient way to load relation data into either the operating system buffer cache or the Postgres Pro buffer cache. Prewarming can be performed manually using the `pg_prewarm` function, or can be performed automatically by including `pg_prewarm` in [shared_preload_libraries](#). In the latter case, the system will run a background worker which periodically records the contents of shared buffers in a file called `autoprewarm.blocks` and will, using 2 background workers, reload those same blocks after a restart.

F.41.1. Functions

```
pg_prewarm(regclass, mode text default 'buffer', fork text default 'main',  
           first_block int8 default null,  
           last_block int8 default null) RETURNS int8
```

The first argument is the relation to be prewarmed. The second argument is the prewarming method to be used, as further discussed below; the third is the relation fork to be prewarmed, usually `main`. The fourth argument is the first block number to prewarm (`NULL` is accepted as a synonym for zero). The fifth argument is the last block number to prewarm (`NULL` means prewarm through the last block in the relation). The return value is the number of blocks prewarmed.

There are three available prewarming methods. `prefetch` issues asynchronous prefetch requests to the operating system, if this is supported, or throws an error otherwise. `read` reads the requested range of blocks; unlike `prefetch`, this is synchronous and supported on all platforms and builds, but may be slower. `buffer` reads the requested range of blocks into the database buffer cache.

Note that with any of these methods, attempting to prewarm more blocks than can be cached — by the OS when using `prefetch` or `read`, or by Postgres Pro when using `buffer` — will likely result in lower-numbered blocks being evicted as higher numbered blocks are read in. Prewarmed data also enjoys no special protection from cache evictions, so it is possible that other system activity may evict the newly prewarmed blocks shortly after they are read; conversely, prewarming may also evict other data from cache. For these reasons, prewarming is typically most useful at startup, when caches are largely empty.

```
autoprewarm_start_worker() RETURNS void
```

Launch the main autoprewarm worker. This will normally happen automatically, but is useful if automatic prewarm was not configured at server startup time and you wish to start up the worker at a later time.

```
autoprewarm_dump_now() RETURNS int8
```

Update `autoprewarm.blocks` immediately. This may be useful if the autoprewarm worker is not running but you anticipate running it after the next restart. The return value is the number of records written to `autoprewarm.blocks`.

F.41.2. Configuration Parameters

```
pg_prewarm.autoprewarm (boolean)
```

Controls whether the server should run the autoprewarm worker. This is on by default. This parameter can only be set at server start.

```
pg_prewarm.autoprewarm_interval (int)
```

This is the interval between updates to `autoprewarm.blocks`. The default is 300 seconds. If set to 0, the file will not be dumped at regular intervals, but only when the server is shut down.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_prewarm'

pg_prewarm.autoprewarm = true
pg_prewarm.autoprewarm_interval = 300s
```

F.41.3. Author

Robert Haas <rahas@postgresql.org>

F.42. pgpro_scheduler

`pgpro_scheduler` is a built-in Postgres Pro Enterprise extension for scheduling, monitoring, and managing job execution within the Postgres Pro Enterprise database. With `pgpro_scheduler`, you can:

- Set advanced schedules using `jsonb` objects or `crontab` strings.
- Dynamically calculate the next execution time for repeated jobs.
- Execute SQL commands of the job in a single transaction or in sequential transactions, if required.
- Submit jobs for immediate or delayed one-time execution in parallel with the scheduled jobs.

Unlike external scheduling daemons, `pgpro_scheduler` offers the following benefits:

- Any user can schedule jobs independently.
- Job scheduling can be managed on the fly without restarting the database.
- Scheduling is very lightweight since `pgpro_scheduler` uses background workers to schedule, monitor, and manage job execution. At the same time, `pgpro_scheduler` does not require any client connections for scheduling.
- For enhanced stability, each database has its own supervisor scheduler, with each scheduled job executed by a separate background worker.

Note

`pgpro_scheduler` waits in the suspended state on a standby server to be started when the standby is promoted to a master server.

Note

Note that for all the executed jobs, the `pg_stat_activity` view will still show the name of the database superuser, which is used by the background worker.

F.42.1. Installation and Setup

The `pgpro_scheduler` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `pgpro_scheduler`:

1. Add `pgpro_scheduler` to the `shared_preload_libraries` parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_scheduler'
```

2. Create the `pgpro_scheduler` extension using the following query:

```
CREATE EXTENSION pgpro_scheduler;
```

Make sure to create the `pgpro_scheduler` extension for each database you are planning to use.

Once you complete the installation and setup, configure `pgpro_scheduler` for your database.

F.42.2. Configuration

You must have superuser rights to configure `pgpro_scheduler`.

To configure `pgpro_scheduler`, modify the following settings in the `postgresql.conf` file:

1. Specify the names of the databases for which you need to schedule jobs, in the comma-separated format:

```
schedule.database = 'database1,database2'
```

2. To control the workload in your system, set the maximum number of background workers that can run simultaneously on each database:

```
schedule.max_workers = 5
```

3. Optionally, set the number of background workers available for one-time job execution:

```
schedule.max_parallel_workers = 3
```

By default, two background workers for one-time jobs are available. These workers are not included into the `schedule.max_workers` number. Thus, one-time jobs can run in parallel with the scheduled jobs even if all the `schedule.max_workers` workers are busy.

4. Run `pg_reload_conf()` for the changes to take effect:

```
SELECT pg_reload_conf();
```

Important

When setting the `schedule.max_workers` variable, make sure to leave enough workers for the rest of the system as other subsystems may also use background workers. The `schedule.max_workers` value cannot exceed the total number of workers enabled by the `max_worker_processes` PostgreSQL Pro variable.

The `pgpro_scheduler` extension starts a separate background worker for the system, each database, and each executed job. For example, if you work with two databases and set the maximum number of workers and parallel workers to 5 and 3, respectively, `pgpro_scheduler` can use up to 19 workers at peak times: one worker is supervising the system, two workers are monitoring the two databases, and each database uses five workers for job scheduling and three workers for running one-time jobs. If all background workers are busy, the jobs will wait for the next available worker. Scheduled and one-time jobs have separate job queues.

If required, you can later change the number of workers. The running jobs will not be affected.

You can also dynamically configure `pgpro_scheduler` from the command line. In this case, you can set different number of workers for different databases:

```
ALTER SYSTEM SET schedule.database = 'database1,database2';
ALTER DATABASE database1 SET schedule.max_workers = 5;
ALTER DATABASE database2 SET schedule.max_workers = 3;
ALTER SYSTEM SET schedule.max_parallel_workers = 3;
SELECT pg_reload_conf();
```

Once `pgpro_scheduler` is configured, enable it on your system, as follows:

```
SELECT schedule.enable();
```

If this function returns `true`, `pgpro_scheduler` is ready to use, and you can start scheduling jobs as explained in [Section F.42.3.1](#) and [Section F.42.3.2](#).

Note

If you restart the server, `pgpro_scheduler` is not automatically restarted by default. To change this behavior, you can set the `schedule.auto_enabled` parameter to `on`.

[Section F.42.4.1](#)

F.42.3. Usage

F.42.3.1. Creating Scheduled Jobs

To create and schedule a job, run the `create_job()` function that takes scheduling options as a `jsonb` object:

```
schedule.create_job(options jsonb)
```

In the `jsonb` object, you must specify one or more SQL commands in the `commands` key, and set the job schedule with at least one of the following keys:

- `dates` — a single date or an array of dates, in the `timestamp with time zone` format
- `cron` — a string, in the `crontab` format. A traditional five-field `crontab` format is used. The first field stands for minute, the second — for hour, the third — for day of the month, the fourth — for month, and the fifth — for day of the week. A six-field `crontab` format can be used alongside the traditional five-field format. In this case the first field stands for second. When you use the six-field format and do not want to specify a second you have to put 0 in the first field.

Alternatively, the following keywords can be used instead of a `crontab` string to specify when the job will be started:

- `@every_second` — each second
- `@hourly` — at the beginning of each hour
- `@daily` — at the beginning of each day
- `@midnight` — at the beginning of each day
- `@weekly` — at the beginning of each week
- `@monthly` — at the beginning of each month
- `@yearly` — at the beginning of each year
- `@annually` — at the beginning of each year
- `rule` — a `jsonb` object that includes one or more of the following keys:
 - `seconds` — seconds; an array of integers in range [0, 59]
 - `minutes` — minutes; an array of integers in range [0, 59]
 - `hours` — hours; an array of integers in range [0, 23]
 - `days` — days of the month; an array of integers in range [1, 31]
 - `months` — months; an array of integers in range [1, 12]
 - `wdays` — days of the week; an array of integers in range [0, 6], where 0 is Sunday.

- `onstart` — integer value 0 or 1. If `onstart` is set to 1, the job is executed only once when `pgpro_scheduler` is started.

You can combine `dates`, `cron`, and `rule` scheduling keys for advanced use cases.

As a result, `pgpro_scheduler` creates an active job with the specified schedule and returns the job ID.

Tip

For simple job schedules, you can use the following shortcut syntax:

```
schedule.create_job(cron, commands)
schedule.create_job(dates, commands)
```

For details, see [schedule.create_job\(\)](#) function description.

If required, you can later modify one or more scheduling options with the `set_job_attribute()` or `set_job_attributes()` functions, respectively.

If all background workers are busy at the specified time, the job waits for the next available worker. By default, the job can wait forever. You can limit the maximum wait time by setting the `last_start_available` key, in the [time interval](#) format. If the timeout is reached, `pgpro_scheduler` cancels the job execution.

Examples:

To run the job every day at 3pm, and, additionally, on December 31, 2017 at 7pm , and on April 4, 2020 at 1pm:

```
SELECT schedule.create_job('{ "commands": "SELECT 15", "cron": "0 15 * * *", "dates":
[ "2017-12-31 19:00", "2020-04-04 13:00" ] }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * *
*", "last_start_available": "30 seconds" }');
```

F.42.3.1.1. Specifying the Time Window for Job Execution

In addition to the general schedule, you can specify the timeframe during which the scheduled job can be executed. To ensure that `pgpro_scheduler` only executes the job within the specified time window, define the `start_date` and `end_date` keys, in the timestamp with time zone format. You can set one of these keys only to limit the start or the end time, respectively. If you define a time window for the job, `pgpro_scheduler` will only schedule this job within this time window. If the started job is incomplete when the specified time window ends, `pgpro_scheduler` completes the job and then excludes the job from further scheduling.

Examples:

To start scheduling the job only after 11am on May 1, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00" }');
```

To schedule the job in the timeframe from 11am on May 1 to 3pm on June 4, 2017:

```
SELECT schedule.create_job('{ "commands": "SELECT now()", "cron": "2 17 * * *",
"start_date": "2017-05-01 11:00", "end_date": "2017-06-04 15:00" }');
```

F.42.3.1.2. Running SQL Commands in Separate Transactions

The `commands` key can have values of text and array types. If you specify several SQL commands as text separated by semicolons, the whole job is executed in a single transaction. If it is critical to perform

each SQL command in a separate transaction, pass the SQL commands as an array. You can modify this behavior by setting the `use_same_transaction` key to `true`. In this case, SQL commands in the array are executed in a single transaction.

Examples:

To run the whole job in a single transaction:

```
SELECT schedule.create_job('{ "commands": "SELECT 1; SELECT 2; SELECT 3;", "cron": "23
23 */2 * *" }');
```

To run commands in separate transactions:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
"cron": "23 23 */2 * *" }');
```

To run the whole job in a single transaction when passing the commands as an array:

```
SELECT schedule.create_job('{ "commands": [ "SELECT 1", "SELECT 2", "SELECT 3" ],
"cron": "23 23 */2 * *", "use_same_transaction": true }');
```

F.42.3.1.3. Calculating the Next Start Time of the Scheduled Job

For repeated jobs, the next start time can be computed by an SQL statement specified in the `next_time_statement` key. In this case, the first job starts on schedule, while all the successive job runs occur at the computed times.

After the job run completes, `pgpro_scheduler` executes the SQL statement in the `next_time_statement` key to calculate the next start time and returns the result, in the `timestamp with time zone` type. If the return value is of a different type or an error occurs, `pgpro_scheduler` marks the job as broken and cancels any further execution. This process is repeated for each successive job run.

Tip

When the job run completes, `pgpro_scheduler` sets the transaction state in the `schedule.transaction_state` variable, in the `text` format. You can use this variable in your `next_time_statement` to dynamically calculate the next start time depending on the transaction state. At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values for the main transaction. Other values may indicate an internal `pgpro_scheduler` error.

Examples:

To run the job first at 10:45, and then in a day after the job completes:

```
SELECT schedule.create_job('{ "commands": "SELECT random()", "cron": "45 10 * * *",
"next_time_statement": "SELECT now() + '1 day'::interval" }');
```

F.42.3.1.4. Setting Additional Conditions for Job Execution

The `pgpro_scheduler` extension enables you to define additional conditions for task execution:

- Set time limits for job execution with the `max_run_time` key. If the execution time is exceeded, `pgpro_scheduler` cancels the job.
- Define the maximum time a scheduled job can wait for execution using the `last_start_available` key. If the timeout is reached, `pgpro_scheduler` cancels the job.
- Schedule a job to be executed with the rights of another user by specifying the `run_as` key. You must have superuser rights to use this key.
- Define an SQL command to execute if the main command fails using the `onrollback` key.

Examples:

To limit job execution to 5 seconds:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(10)", "cron": "15 */10 * * *", "max_run_time": "5 seconds" }');
```

To limit the wait time for job execution to 30 seconds after the scheduled time:

```
SELECT schedule.create_job('{ "commands": "SELECT pg_sleep(100)", "cron": "15 */2 * * *", "last_start_available": "30 seconds" }');
```

To start the job with the rights of the `robot` user:

```
SELECT schedule.create_job('{ "commands": "SELECT session_user", "cron": "5 */5 * * *", "run_as": "robot" }');
```

To define a fallback SQL command in case the main command fails:

```
SELECT schedule.create_job('{ "commands": "SELECT ''zzz''", "cron": "55 */12 * * *", "onrollback": "SELECT ''Cannot select zzz''" }');
```

F.42.3.2. Submitting One-Time Jobs

You can submit jobs for one-time execution using the `schedule.submit_job()` function. Such jobs use a separate pool of background workers defined by the `schedule.max_parallel_workers` variable, and can run in parallel with the scheduled jobs. By default, two one-time jobs can run concurrently. If you submit more jobs, they will wait in the queue for the next available background worker.

To execute a one-time job immediately, pass SQL commands in the `query` argument. For example:

```
schedule.submit_job(query := 'select 1');
```

Instead of passing SQL query parameters directly, you can define numbered placeholders in the `query` argument, such as `$1` and `$2`, and pass an array of parameters in the `params` argument, with each array element corresponding to a placeholder. For brevity, you can omit the `query` and `params` names:

```
schedule.submit_job(query := 'select $1, $2', params := '{"text 1", "text 2"}')
```

To start a one-time job at the specified time, use the `run_after` argument:

```
schedule.submit_job('select ''flowers''', run_after := '2017-03-08 08:00:01');
```

Alternatively, you can delay the job start until the specified jobs are complete using the `depends_on` argument. For example, to run a job after completing the jobs with 23, 15, and 334 IDs, run:

```
schedule.submit_job('select ''well done''', depends_on := '{23, 15, 334}')
```

If required, you can repeat the job execution by passing the `schedule.resubmit()` function as part of the `query` argument. For example:

```
schedule.submit_job('select 1, schedule.resubmit(run_after := ''5'')');
```

The `run_after` argument specifies the time interval before the job is restarted, in seconds. By default, the interval is 1 second.

The resubmitted job cannot be executed more than the number of times set in the `resubmit_limit` argument. If this limit is reached, the job receives the `done` status, with the corresponding error message.

If you want to cancel a resubmitted job, run:

```
schedule.cancel_job(job_id bigint);
```

To monitor one-time jobs, use the [job_status](#) and [all_job_status](#) `pgpro_scheduler` views.

For details on all the functions available for managing one-time jobs, see [Section F.42.4.6.3](#).

F.42.3.3. Changing and Removing Scheduled Jobs

When you create a new job with the `create_job()` function, the job becomes active and waits for execution based on the specified schedule. Using the job ID returned by the `create_job()` function, you can change the scheduling settings or remove the job from the schedule. To change the specified schedule for the jobs, use `set_job_attribute()` or `set_job_attributes()` functions:

- To modify a single property of the job, run the `set_job_attribute()` function with the job ID, the property name to change, and the new value for this property.
- To modify more than one property of the job, run the `set_job_attributes()` function instead. In this case, you can specify all the job properties at once in a `jsonb` object. For details on all the keys available for job scheduling, see the `create_job()` function description.

To temporarily exclude the job from scheduling, run the `deactivate_job()` function:

```
schedule.deactivate_job(job_id integer)
```

You can re-activate the job later by running the `activate_job()` function:

```
schedule.activate_job(job_id integer)
```

To permanently remove the job from the schedule, run the `drop_job()` function:

```
schedule.drop_job(job_id integer)
```

F.42.3.4. Monitoring Scheduled Jobs

You must have superuser rights to monitor job execution for the whole system. Otherwise, you can only monitor the jobs that you own. To monitor scheduled jobs, `pgpro_scheduler` provides multiple functions that return `cron_rec` or `cron_job` records:

- `get_job()` — retrieves information about the job.
- `get_owned_cron()` — retrieves the list of jobs owned by user.
- `get_cron()` — retrieves the list of jobs executed by user.
- `get_active_jobs()` — returns the list of jobs executed at the moment of the function call.
- `get_log()` — returns the list of all completed jobs.
- `get_user_log()` — returns list of the completed jobs executed by the specified user.
- `clean_log()` — deletes all records with information about completed jobs.

To learn more about each function, see [Section F.42.4.6](#).

F.42.3.5. Auditing Job Scheduling

`pgpro_scheduler` enables you to audit job scheduling to rule out human error if you observe unexpected changes in scheduled job execution.

By default, `pgpro_scheduler` does not store information on schedule changes. To enable this feature, set the `schedule.enable_history` parameter to `true`. Once this parameter is enabled, `pgpro_scheduler` stores schedule modifications in the `schedule.cron__history` table, and logs all deleted jobs in the `schedule.cron__deleted` table. Logged history is never deleted from these tables, so a superuser can review schedule changes introduced by all users at any time.

For details on logged information, see [Section F.42.4.5](#).

F.42.3.6. Scheduling Jobs on a Multi-Master Cluster

Using `pgpro_scheduler`, you can manage scheduled and one-time jobs on a cluster configured with `multimaster`. `pgpro_scheduler` can only manage jobs on the node on which it is installed. Thus, you

must install and enable `pgpro_scheduler` on all nodes on which you would like to schedule jobs. `pgpro_scheduler` instances will manage jobs on different nodes independently, but the executed jobs will be replicated to other nodes.

Even if you are planning to schedule jobs on a single node only, it is recommended to enable `pgpro_scheduler` on several nodes. In this case, if a node with scheduled jobs fails, another `pgpro_scheduler` instance picks up these jobs. If `pgpro_scheduler` is running on more than one node, the node with the smallest node ID is selected. The naming pattern of node IDs is defined by the [schedule.nodename](#) GUC variable.

F.42.4. Reference

F.42.4.1. GUC Variables

`schedule.enabled` (boolean)

Deprecated. Specifies whether `pgpro_scheduler` is enabled on your system.

Default: `false`.

For `pgpro_scheduler` 2.5 or higher, you can set the [schedule.auto_enabled](#) parameter to control whether `pgpro_scheduler` is enabled at the server start, or use `schedule.enable()/schedule.disable()` functions to enable/disable `pgpro_scheduler` on demand. To check if `pgpro_scheduler` is currently running, use the `schedule.is_enabled()` function.

`schedule.auto_enabled` (boolean)

Specifies whether to enable `pgpro_scheduler` at the server start.

Default: `false`.

`schedule.database` (text)

Specifies the databases for which `pgpro_scheduler` is enabled. Database names must be separated by commas.

Default: empty string.

`schedule.database_to_connect` (text)

The database to which `pgpro_scheduler` gets connected to receive Postgres Pro Enterprise cluster metadata. The specified database cannot be dropped while `pgpro_scheduler` is running. You can change this parameter only when restarting the server.

Default: `postgres`.

`schedule.schema` (text)

Deprecated. Specifies the name of a schema where the scheduler stores its tables and functions. If you need to change the default schema, use [ALTER EXTENSION](#).

Default: `schedule`.

`schedule.nodename` (text)

Specifies the name of the cluster node on which `pgpro_scheduler` is running. Do not change or use this variable if you run a single-server cluster configuration.

On a cluster configured with `multimaster`, the node name is derived from the node ID provided by `multimaster`. For example, if the node ID is 3, the `schedule.nodename` variable is set to `mtm-node-3`. However, if you explicitly set the `schedule.nodename` variable by editing the `postgresql.conf` file

or running the `ALTER` command, `pgpro_scheduler` will ignore the node ID and use the provided value instead.

Default: `master`.

`schedule.max_workers` (integer)

Specifies the maximum number of simultaneously running scheduled jobs in one database.

Default: 2.

`schedule.max_parallel_workers` (integer)

Specifies the maximum number of parallel threads that can be used for executing one-time jobs.

Default: 2.

`schedule.transaction_state` (text)

An internal variable containing the state of the executed job. `pgpro_scheduler` uses this variable when calculating the next job start time. Possible values are:

- `success` — transaction has finished successfully.
- `failure` — transaction has failed to finish.
- `running` — transaction is in progress.
- `undefined` — transaction has not started yet.

At the time of the `next_time_statement` execution, the `schedule.transaction_state` variable must contain either `success` or `failure` state values. Other values may indicate an internal `pgpro_scheduler` error.

`schedule.enable_history` (boolean)

Log all schedule changes, including the name of the user who initiated the change and the time when this change occurred. If a new job is added, or the schedule of an existing job is modified, this information is stored in the `schedule.cron__history` table. If a job is deleted, this information is stored in the `schedule.cron__deleted` table. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

Default: `false`

F.42.4.2. SQL Schema

To store its internal tables and functions, `pgpro_scheduler` uses the `schedule` SQL schema. Direct access to tables is not recommended and should not be attempted. To manage job scheduling, use the functions defined by the `pgpro_scheduler` extension.

F.42.4.3. SQL Types

`pgpro_scheduler` defines the following types that are used by some of the `pgpro_scheduler` functions.

F.42.4.3.1. `cron_rec`

This type contains information about the scheduled job.

```
CREATE TYPE schedule.cron_rec AS (  
    id integer,           -- job ID  
    node text,            -- name of the node  
                        -- on which to execute the job  
    name text,            -- job name  
    comments text,        -- comments about the job
```

```

rule jsonb,           -- scheduling rules
commands text[],      -- SQL commands to be executed
run_as text,          -- username of the job executor
owner text,           -- username of the job owner
start_date timestamptz, -- lower bound of the execution window;
                      -- NULL if unbound
end_date timestamptz, -- upper bound of the execution window;
                      -- NULL if unbound
use_same_transaction boolean, -- true if an array of SQL
                              -- commands will be executed
                              -- in a single transaction
last_start_available interval, -- maximum wait time for
                              -- the scheduled job if all
                              -- allowed workers are busy
max_run_time interval, -- maximum execution time
onrollback text,       -- SQL statement to execute
                      -- if the main transaction fails
max_instances int,     -- maximum number of simultaneously
                      -- running job instances
next_time_statement text, -- SQL statement to calculate
                      -- the next start time
active boolean,        -- true if job is scheduled
                      -- successfully
broken boolean         -- true if job has errors in
                      -- configuration that prevented
                      -- its further execution
);

```

F.42.4.3.2. cron_job

This type contains information about a particular job execution.

```

CREATE TYPE schedule.cron_job AS(
  cron integer,           -- job id
  node text,              -- name of the node
                      -- on which to execute the job
  scheduled_at timestamptz, -- scheduled execution time
  name text,              -- job name
  comments text,          -- comments about the job
  commands text[],        -- SQL statement to be executed
  run_as text,            -- username of the job executor
  owner text,             -- username of the job owner
  use_same_transaction boolean, -- true if an array of SQL
                              -- commands will be executed
                              -- in a single transaction
  started timestamptz,     -- timestamp of the job execution start
  last_start_available timestamp, -- maximum wait time for
                              -- the scheduled job if all
                              -- allowed workers are busy
  finished timestamptz,    -- timestamp of the job
                              -- execution finish
  max_run_time interval,  -- maximum execution time
  onrollback text,        -- SQL statement to execute if the main
                              -- transaction fails
  next_time_statement text, -- SQL statement to calculate
                              -- the next start time
  max_instances int,       -- the number of simultaneously
                              -- running job instances
  status job_status_t,     -- status of the task:

```

```
message text          -- working, done, or error
);                    -- error message
```

F.42.4.3.3. `job_status_t`

Enumerated type. Can take the following values:

- `working` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.

F.42.4.3.4. `job_at_status_t`

Enumerated type. Can take the following values:

- `submitted` — the job is submitted into the queue, but the execution has not started yet.
- `processing` — the job is being executed.
- `done` — job execution is complete.

F.42.4.3.5. `timetable_job_type_t`

Enumerated type. Can take the following values:

- `periodical` — a scheduled job.
- `onetime` — a one-time job.

F.42.4.3.6. `timetable_job_status_t`

Enumerated type. Can take the following values:

- `inprogress` — the job is being executed.
- `done` — job execution is complete.
- `error` — job execution has failed.
- `submitted` — the job is submitted into the queue, but the execution has not started yet.

F.42.4.4. Views

`pgpro_scheduler` provides several views for monitoring execution status of one-time jobs.

F.42.4.4.1. `job_status` View

Shows the status of one-time jobs belonging to the current user.

Table F.90. `job_status` View

Column Name	Column Type	Description
<code>id</code>	<code>bigint</code>	Job ID.
<code>node</code>	<code>text</code>	Name of the node on which the job is being executed.
<code>name</code>	<code>text</code>	Name of the job.
<code>comments</code>	<code>text</code>	Comments about the job.
<code>run_after</code>	<code>timestamp with time zone</code>	Timestamp after which the job execution must start.
<code>query</code>	<code>text</code>	SQL commands executed by the job.

Column Name	Column Type	Description
params	text []	An array of parameters for the SQL query.
depends_on	bigint []	An array of job IDs on which the job execution depends.
run_as	text	User or role whose rights are used to execute the job.
attempt	bigint	The number of execution attempts.
resubmit_limit	bigint	The maximum number of allowed job resubmissions.
max_wait_interval	interval	The maximum time interval to postpone the job execution if all background workers are busy at the scheduled moment.
max_duration	interval	Time interval during which the job can be executed.
submit_time	timestamp with time zone	Time when the job was submitted to the execution queue.
canceled	boolean	Specifies whether the job was canceled by user.
start_time	timestamp with time zone	Job execution start time.
is_success	boolean	• true — job execution completed successfully. • false — job execution completed with errors.
error	text	Error message.
done_time	timestamp with time zone	Time when the job execution completed.
status	job_at_status_t	Job status. See the Section F.42.4.3.4 for details.

F.42.4.4.2. all_job_status View

Shows the status of all one-time jobs. You must have superuser rights to access this view.

Table F.91. all_job_status View

Column Name	Column Type	Description
id	bigint	Job ID.
node	text	Name of the node on which the job is being executed.
name	text	Name of the job.
comments	text	Comments about the job.
run_after	timestamp with time zone	Timestamp after which the job execution must start.
query	text	SQL commands executed by the job.
params	text []	An array of parameters for the SQL query.

Column Name	Column Type	Description
depends_on	bigint[]	An array of job IDs on which the job execution depends.
run_as	text	User or role whose rights are used to execute the job.
owner	text	The user who created the job.
attempt	bigint	The number of execution attempts.
resubmit_limit	bigint	The maximum number of allowed job resubmissions.
max_wait_interval	interval	The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment.
max_duration	interval	Time interval during which the job can be executed.
submit_time	timestamp with time zone	Time when the job was submitted to the execution queue.
canceled	boolean	Specifies whether the job was canceled by user.
start_time	timestamp with time zone	Job execution start time.
is_success	boolean	• <code>true</code> — job execution completed successfully. • <code>false</code> — job execution completed with errors.
error	text	Error message.
done_time	timestamp with time zone	Time when the job execution completed.
status	job_at_status_t	Job status. See the Section F.42.4.3.4 for details.

F.42.4.5. Audit Tables

The following tables store all schedule changes if the `schedule.enable_history` parameter is set to `true`. If you later disable the `schedule.enable_history` parameter, the history of the already recorded changes is preserved.

F.42.4.5.1. `schedule.cron_history` Table

Registers job scheduling changes. Whenever a new job is scheduled, or the schedule for an existing job is changed, a new row is inserted into this table to record the following information:

- All details about the scheduled job, as defined by the `cron_rec` data type. For details on the `cron_rec` type, see [Section F.42.4.3](#).
- `submitter` — name of the user who updated the schedule.
- `version_id` — a unique ID for each registered change in the schedule.
- `submit_time` — time when the schedule was updated.

F.42.4.5.2. `schedule.cron_deleted` Table

Registers all jobs that were removed from the schedule:

- `cron` — ID of the deleted job.

- `submitter` — name of the user who deleted the job.
- `submit_time` — time when the job was deleted.

F.42.4.6. Functions

`pgpro_scheduler` provides two separate sets of functions for managing scheduled and one-time jobs, as well as several common functions that can toggle `pgpro_scheduler` on and off for your database and show the current status of the extension:

- [Section F.42.4.6.1](#)
- [Section F.42.4.6.2](#)
- [Section F.42.4.6.3](#)
- [Section F.42.4.6.4](#)

Important

With each job, you can only use the function specifically tailored for this job type.

F.42.4.6.1. Common Functions

These functions facilitate `pgpro_scheduler` management.

`schedule.enable()`

Enables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if the command has failed.

`schedule.is_enabled()`

Checks whether `pgpro_scheduler` is enabled.

Return values:

- `true` if `pgpro_scheduler` is enabled and ready to use.
- `false` if `pgpro_scheduler` is not currently running.

`schedule.disable()`

Disables `pgpro_scheduler` for the current Postgres Pro Enterprise instance.

Return values:

- `true` if `pgpro_scheduler` is disabled.
- `false` if the command has failed.

`schedule.start()`

Launches `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` started successfully.
- `false` — if the command has failed, or `pgpro_scheduler` is already started.

`schedule.stop()`

Stops `pgpro_scheduler` for the currently connected database.

Return values:

- `true` — `pgpro_scheduler` is stopped.
- `false` — if the command has failed, or `pgpro_scheduler` is not running.

`schedule.status()`

Returns the status of `pgpro_scheduler` background workers:

- `pid` — process ID of the background worker. If the process ID is `NULL`, the background worker is not running.
- `database` — name of the database to which the background worker is connected.
- `type` — type of the background worker:
 - `supervisor` — distributes the scheduled jobs between the databases.
 - `database manager` distributes the scheduled jobs within the database.
 - `cron job executor` executes a scheduled job.
 - `at job executor` executes a one-time job.

`schedule.version()`

Returns `pgpro_scheduler` version.

F.42.4.6.2. Functions for Managing Scheduled Jobs

`schedule.create_job(options jsonb)`

Creates an active job and returns the job ID.

Alternative Syntax:

```
schedule.create_job(cron text, commands text [, node text])
schedule.create_job(cron text, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone, commands text [, node text])
schedule.create_job(dates timestamp with time zone, commands text[] [, node text])
schedule.create_job(dates timestamp with time zone[], commands text [, node text])
schedule.create_job(dates timestamp with time zone[], commands text[] [, node text])
```

Arguments:

- `options` — a `jsonb` object defining all the job properties. You do not need to define other parameters if the `data` is set. All the available `jsonb` keys are listed in [Table F.92](#).

Type: `jsonb`

- `cron` — a crontab-like string defining the job schedule.

Type: `text`

- `dates` — the exact date or an array of dates for job execution.

Type: `timestamp with time zone, timestamp with time zone[]`

- `commands` — SQL statement to execute. You can pass one or more SQL commands separated by semicolons, or an array of SQL commands. When passed as an array, SQL commands are executed in separate transactions.

Type: `text, text[]`

- `node` — the name of the node on which the scheduled jobs run. Optional. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.

Type: `text`

Return values:

- ID of the created job.

Table F.92. jsonb Keys for Job Scheduling

Key	Type	Description
cron	text	A crontab-like string defining the job schedule. A traditional five-field or nonstandard six-field (seconds in the first field) crontab format may be used. You can combine <code>cron</code> with <code>rule</code> and <code>dates</code> keys, but at least one of them is mandatory. Alternatively, the following keywords can be used instead of a crontab string to specify when the job will be started: • <code>@every_second</code> — each second • <code>@hourly</code> — at the beginning of each hour • <code>@daily</code> — at the beginning of each day • <code>@midnight</code> — at the beginning of each day • <code>@weekly</code> — at the beginning of each week • <code>@monthly</code> — at the beginning of each month • <code>@yearly</code> — at the beginning of each year • <code>@annually</code> — at the beginning of each year
dates	timestamp with time zone, timestamp with time zone[]	The exact date or an array of dates when the scheduled job will be executed. You can combine <code>dates</code> with <code>rule</code> and <code>cron</code> keys, but at least one of them is mandatory.
rule	jsonb	A jsonb object defining the job schedule. Mandatory, if both <code>cron</code> and <code>dates</code> keys are undefined. The <code>rule</code> object includes one or more of the following keys: • <code>seconds</code> — seconds; an array of integers in range [0, 59] • <code>minutes</code> — minutes; an array of integers in range [0, 59] • <code>hours</code> — hours; an array of integers in range [0, 23]

Key	Type	Description
		<code>days</code> — days of the month; an array of integers in range [1, 31] <code>months</code> — months; an array of integers in range [1, 12] <code>wdays</code> — days of the week; an array of integers in range [0, 6], where 0 is Sunday. <code>onstart</code> — integer value 0 or 1. If <code>onstart</code> is set to 1, the job is executed only once when <code>pgpro_scheduler</code> is started.
<code>commands</code>	<code>text, text[]</code>	SQL statements to execute. You can pass one or more SQL statements separated by semicolons, or an array of SQL statements. When passed as an array, SQL statements are executed in separate transactions by default. You can change this behavior by setting the <code>use_same_transaction</code> key.
<code>name</code>	<code>text</code>	Optional. Job name.
<code>node</code>	<code>text</code>	Optional. The name of the node on which the scheduled jobs run. You may need to specify this argument if you are scheduling jobs on a multi-master cluster.
<code>comments</code>	<code>text</code>	Optional. Comments about the scheduled job.
<code>run_as</code>	<code>text</code>	Optional. The user whose rights are used to execute the job.
<code>start_date</code>	<code>timestamp with time zone</code>	Optional. The start of the time-frame when the scheduled job can be executed. This key can be <code>NULL</code> .
<code>end_date</code>	<code>timestamp with time zone</code>	Optional. The end of the time-frame when the scheduled job can be executed. This key can be <code>NULL</code> .
<code>use_same_transaction</code>	<code>boolean</code>	Optional. If set to <code>true</code> , forces an array of SQL statements to be executed in a single transaction. Default: <code>false</code>
<code>last_start_available</code>	<code>interval</code>	Optional. The maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if

Key	Type	Description
		this key is set to '00:02:34', the job will wait for 2 minutes 34 seconds. If this key is <code>NULL</code> or not set, the job can wait forever. Default: <code>NULL</code> .
<code>max_instances</code>	<code>integer</code>	Optional. The maximum number of job instances that can be executed simultaneously. Default: 1.
<code>max_run_time</code>	<code>interval</code>	Optional. The maximum time interval during which the scheduled job can be executed. If this key is <code>NULL</code> or not set, there are no time limits. Default: <code>NULL</code> .
<code>onrollback</code>	<code>text</code>	Optional. SQL statement to be executed if the main transaction fails.
<code>next_time_statement</code>	<code>text</code>	Optional. SQL statement to calculate the start time for the next job execution. For details, see Section F.42.3.1.3 .

```
schedule.set_job_attributes(job_id integer, data jsonb)
```

Updates properties of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `data` — a `jsonb` object with properties to be edited. For the list of keys and their structure, see [Table F.92](#).

Return values:

- `true` — job properties were updated successfully.
- `false` — job properties were not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

```
schedule.set_job_attribute(job_id integer, name text, value text || anyarray)
```

Updates a property of the existing job.

Arguments:

- `job_id` — identifier of the existing job.
- `name` — property name.
- `value` — property value.

See [Table F.92](#) for the list of job properties you can update. Some values are of array types. They should be passed as an array. If a value of a wrong type is passed, an exception is raised.

Return values:

- `true` — job property was updated successfully.

- *false* — job property was not updated.

To update the job properties, you must be the owner of the job or have superuser rights.

`schedule.deactivate_job(job_id integer)`

Deactivates the job and suspends its further scheduling and execution.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- *true* — the job is deactivated successfully.
- *false* — job deactivation failed.

`schedule.activate_job(job_id integer)`

Activates a job and starts its scheduling and execution.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- *true* — the job was activated successfully.
- *false* — job activation failed.

`schedule.drop_job(job_id integer)`

Deletes a job.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- *true* — the job was deleted successfully.
- *false* — job was not deleted.

`schedule.get_job(job_id integer)`

Returns information about the specified job.

Arguments:

- *job_id* — identifier of the existing job.

Return values:

- An object of type `cron_rec`.

For details on the `cron_rec` type, see [Section F.42.4.3](#).

`schedule.get_owned_cron(username text)`

Retrieves the list of jobs owned by the specified user.

Arguments:

- *username* — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs owned by the specified user. If the `username` is omitted, the session username is used. You must have superuser rights to retrieve jobs owned by another user.

For details on the `cron_rec` type, see [Section F.42.4.3](#).

```
schedule.get_cron(username text)
```

Retrieves the list of jobs executed by the specified user.

Arguments:

- `username` — username, optional.

Return values:

- A set of records of type `cron_rec`. These records contain information about all jobs executed by the specified user. If `username` is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

For details on the `cron_rec` type, see [Section F.42.4.3](#).

```
schedule.get_active_jobs(username text)
```

Returns the list of jobs currently being executed by the specified user.

Arguments:

- `username` — username, optional.

If `username` is omitted, the session username is used. You must have superuser rights to retrieve jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.42.4.3](#).

```
schedule.get_active_jobs()
```

Returns the list of jobs being currently executed. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.42.4.3](#).

```
schedule.get_log()
```

Returns the list of all completed jobs. You must have superuser rights to call this function.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.42.4.3](#).

```
schedule.get_user_log(username text)
```

Returns the list of completed jobs executed by the specified user.

Arguments:

- *username* — username, optional.

If *username* is omitted, the session username is used. You must have superuser rights to retrieve the list of jobs executed by another user.

Return values:

- A set of records of type `cron_job`.

For details on the `cron_job` type, see [Section F.42.4.3](#).

```
schedule.clean_log()
```

Deletes all records with information about the completed jobs. You must have superuser rights to call this function.

Return values:

- The number of records deleted.

```
schedule.nodename()
```

Returns the current node name.

F.42.4.6.3. Functions for Managing One-Time Jobs

```
schedule.submit_job(query text [options...])
```

Submits a job for immediate or delayed one-time execution. By default, the job is scheduled for immediate execution and can run in parallel with other scheduled jobs. To submit a job with a delayed start, you can set the execution start time using the *run_after* argument, or pass an array of job IDs in the *depends_on* argument to schedule job execution right after these jobs are complete.

Arguments:

- *query* — SQL commands to execute.

Type: text

- *params* — an array of parameters for the SQL query that can substitute numbered placeholders in the *query* argument, such as \$1, \$2, etc. Default: NULL

Type: text[]

- *run_after* — a timestamp after which the job execution starts. If this argument is set to NULL, the job is scheduled for immediate execution. You can also use the *depends_on* argument to delay the job start. Default: NULL

Type: timestamp with time zone

- *node* — the name of the node on which to execute the job. Default: NULL

Type: text

- *max_duration* — the maximum time interval during which the job can be executed. If this time is exceeded, the job is forced to stop. If this argument is NULL or not set, there are no time limits. Default: NULL

Type: interval

- *max_wait_interval* — the maximum time interval to postpone the job execution for if all background workers are busy at the scheduled moment. For example, if this key is set to '00:02:34',

the job will wait for 2 minutes 34 seconds. If this key is `NULL` or not set, the job can wait forever.
Default: `NULL`

Type: `interval`

- *run_as* — user or role whose rights are used to execute the job. If *run_as* is set to `NULL`, the job is executed with the rights of the current user. You must have superuser rights to set this argument. Default: `NULL`

Type: `text`

- *depends_on* — an array of job IDs. The created job starts immediately after the specified jobs complete the execution. This argument is an alternative to *run_after*. Default: `NULL`

Type: `bigint[]`

- *name* — name of the job. Default: `NULL`

Type: `text`

- *comments* — comments about the job.

Type: `text`

- *resubmit_limit* — maximum number of times the job can be resubmitted for execution. See the `schedule.resubmit()` function for details. Default: 100

Type: `bigint`

Return values:

- ID of the created job.

Type: `bigint`

`schedule.get_self_id()`

Returns the ID of the job, in the context of which it was called. The returned ID is of the `bigint` type. This function must be called inside the *query* of the `schedule.submit_job()` function. Otherwise, an exception is raised.

Return values:

- Job ID.

`schedule.cancel_job(job_id bigint)`

Cancels all subsequent runs of the specified job. If the job is currently being executed, it will not be interrupted, but cannot be resubmitted. You must have superuser rights or be the owner of the job to call this function.

Arguments:

- *job_id* — identifier of the job to cancel.

Return values:

- `true` if the operation completed successfully.
- `false` if the operation failed.

`schedule.resubmit(run_after interval default NULL)`

Sets the start time for the next execution of the job, without interrupting the current job run. This function must be called inside the *query* argument of the `schedule.submit_job()` function. Other-

wise, an exception is raised. If this function is called several times within a single job execution, only the last function call is taken into account.

Arguments:

- *run_after* — time interval after which the job will be resubmitted for execution. If the time interval is less than a second but greater than zero, it is rounded to 1 second. Intervals longer than 1 second are rounded to integral values. If 0 is passed, the job is resubmitted immediately after execution. Default: 1 second

Type: `interval`

Return values:

- The number of seconds after which the job will be resubmitted for execution.

F.42.4.6.4. Functions for Managing Scheduled and One-Time Jobs

```
schedule.timetable(start_time timestamp with time zone, end_time timestamp with time zone)
```

Returns a table, which describes all the jobs, both repeated and one-time, that are scheduled to execute within the specified time interval.

Table F.93. `schedule.timetable` Columns

Column Name	Column Type	Description
<code>id</code>	<code>bigint</code>	Job ID, which is unique for the jobs of this type.
<code>type</code>	<code>timetable_job_type_t</code>	Job type. See Section F.42.4.3.5 for details.
<code>node</code>	<code>text</code>	Name of the node on which the job is being executed.
<code>name</code>	<code>text</code>	Name of the job.
<code>comments</code>	<code>text</code>	Comments about the job.
<code>commands</code>	<code>text[]</code>	An array of SQL commands executed by the job.
<code>scheduled_at</code>	<code>timestamp with time zone</code>	Scheduled job execution time.
<code>start_time</code>	<code>timestamp with time zone</code>	Job execution start time.
<code>done_time</code>	<code>timestamp with time zone</code>	Time when the job execution completed.
<code>status</code>	<code>timetable_job_status_t</code>	Job status. See Section F.42.4.3.6 for details.
<code>error</code>	<code>text</code>	Error message.

F.42.5. Authors

Postgres Professional, Moscow, Russia

F.43. `pgpro_stats`

The `pgpro_stats` extension provides a means for tracking planning and execution statistics of all SQL statements executed by a server. It is based on the [pg_stat_statements](#) module and provides the following additional functionality:

- Storing query plans in addition to query statements.
- Configuring sample rate for statistics collection to reduce overhead.

- Calculating wait event statistics for executed queries.
- Calculating resource usage statistics of statement planning and execution.
- Calculating cache invalidation statistics.
- Calculating additional archiver statistics.
- Providing an interface to statistics about vacuuming databases, tables, and indexes collected by the core system.
- Tracing of application sessions.
- Creating views that emulate other extensions.

The background information, along with views and types, related to calculating cache invalidation statistics is provided in a separate section [Section F.43.8](#).

F.43.1. Limitations

- `pgpro_stats` can sometimes fail to match identical parameters in the query statement and the corresponding query plan.
- Some SPI queries are not included into statistics.
- Texts and plans of some SPI queries are not normalized.
- `pgpro_stats` is incompatible with [pg_stat_statements](#), as well as other extensions that use parser, planner, or executor hooks to modify parse and plan trees and execution of the queries. Note also that in order to dump the final versions of the queries and plans, `pgpro_stats` should be the last on the list of `shared_preload_libraries`, but some existing extensions, such as `pg_pathman`, will not work at all unless they are the last on this list.
- `pgpro_stats` may not work correctly with third-party extensions that produce `CustomScan` and `ForeignScan` nodes.

F.43.2. Installation and Setup

The `pgpro_stats` extension is included into Postgres Pro Enterprise, but has to be installed separately. Once you have `pgpro_stats` installed, complete the following steps to enable `pgpro_stats`:

1. Add `pgpro_stats` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'pgpro_stats'
```

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.

Once the server is reloaded, `pgpro_stats` starts tracking statistics across all databases of the cluster. If required, you can change the scope of statistics collection or disable it altogether using `pgpro_stats` [configuration parameters](#).

3. To access the collected statistics, you have to create `pgpro_stats` extension:

```
CREATE EXTENSION pgpro_stats;
```

F.43.3. Usage

- [Collecting Statistics on Query Statements and Plans](#)
- [Monitoring Custom Metrics](#)

F.43.3.1. Collecting Statistics on Query Statements and Plans

Once installed, the `pgpro_stats` extension starts collecting statistics on the executed statements. The collected data is similar to the one provided by [pg_stat_statements](#), but also includes information on

query plans and wait events for each query type. The statistics is saved into an in-memory ring buffer and is accessible through the `pgpro_stats_statements` view.

By default, `pgpro_stats` collects statistics on all the executed statements that satisfy the `pgpro_stats.track` and `pgpro_stats.track_utility` settings. If performance is a concern, you can set a sample rate for queries using the `pgpro_stats.query_sample_rate` parameter, and `pgpro_stats` will randomly select queries for statistics calculation at the specified rate.

To collect statistics on wait events, `pgpro_stats` uses time-based sampling. Wait events are sampled at the time interval specified by the `pgpro_stats.profile_period` parameter, which is set to 10ms by default. If the sampling shows that the process is waiting, the `pgpro_stats.profile_period` value is added to the wait event duration. Thus, time estimation for each wait event remains valid even if the `pgpro_stats.profile_period` parameter value has changed. If you are not interested in wait event statistics, you can disable wait event sampling by setting the `pgpro_stats.enable_profile` parameter to `false`.

`pgpro_stats_statements.plans` and `pgpro_stats_statements.calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

As an example, let's create a table with some random data and build an index on this table:

```
CREATE TABLE test AS (SELECT i, random() x FROM generate_series(1,1000000) i);
CREATE INDEX test_x_idx ON test (x);
```

Now run the following query several times using different values for `:x_min` and `:x_max`:

```
select * from test where x >= :x_min and x <= :x_max;
```

The collected statistics should appear in the `pgpro_stats_statements` view:

```
SELECT queryid, query, planid, plan, wait_stats FROM pgpro_stats_statements WHERE query
LIKE 'select * from test where%';
```

```
-[ RECORD
```

```
1 ]-----
queryid      | 1109491335754870054
query        | select * from test where x >= $1 and x <= $2
planid       | 8287793242828473388
plan         | Gather
              |   Output: i, x
              |   Workers Planned: 2
              |   -> Parallel Seq Scan on public.test
              |       Output: i, x
              |       Filter: ((test.x >= $3) AND (test.x <= $4))
              |
```

```

wait_stats   | NULL

```

F.43.3.2. Monitoring Custom Metrics

With `pgpro_stats`, you can define custom metrics to be monitored. The collected data will be saved into an in-memory ring buffer and then sent to a monitoring system. Unlike direct polling of a database by a monitoring system that can lose some data if the connection is interrupted, this approach allows to get all the collected data regardless of connection issues, as long as this data is still available in the ring buffer.

To set up a custom metric to collect, do the following:

1. For each metric, define all configuration parameters listed in [Section F.43.7.2](#). You must specify a unique numeric identifier of each metric in the parameter names.

For example, to monitor index bloating each 60 seconds, you can define a new metric by setting metrics-related parameters as follows:

```

pgpro_stats.metric_1_name = index_bloat
pgpro_stats.metric_1_query = 'select iname, ibloat, ipages from bloat'
pgpro_stats.metric_1_db = 'postgres'
pgpro_stats.metric_1_user = postgres
pgpro_stats.metric_1_period = '60s'

```

2. Restart the server.

`pgpro_stats` starts collecting statistics on executed statements and saves it into the ring buffer, and the collected data appears in the `pgpro_stats_metrics` view:

```
SELECT * FROM pgpro_stats_metrics;
```

Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

3. If required, set up data export to a monitoring system of your choice.

F.43.4. Views

F.43.4.1. The `pgpro_stats_statements` View

The statistics gathered by the module are made available via a view named `pgpro_stats_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.94](#).

Table F.94. pgpro_stats_statements Columns

Name	Type	References	Description
userid	oid	pg_authid .oid	OID of user who executed the statement
dbid	oid	pg_database .oid	OID of database in which the statement was executed
toplevel	bool		True if the query was executed as a top-level statement (always true if pgpro_stats.track is set to <code>top</code>)
queryid	bigint		Internal hash code, computed from the statement's parse tree
planid	bigint		Internal hash code, computed from the statement's plan tree
query	text		Text of a representative statement
plan	text		The text of the query plan, in the format defined by the pgpro_stats.plan_format configuration parameter
plans	int8		Number of times the statement was planned (if pgpro_stats.track_planning is enabled, otherwise zero)
total_plan_time	float8		Total time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero).
min_plan_time	float8		Minimum time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
max_plan_time	float8		Maximum time spent planning the statement, in milliseconds (if pgpro_stats.track_planning is enabled, otherwise zero)
mean_plan_time	float8		Mean time spent planning the statement, in milliseconds (if pgpro_stats.track_planning

Name	Type	References	Description
			is enabled, otherwise zero)
stddev_plan_time	float8		Population standard deviation of time spent planning the statement, in milliseconds (if <code>pgpro_stats.track_planning</code> is enabled, otherwise zero)
plan_rusage	pgpro_stats_rusage		Resource usage statistics of the statement planning.
calls	int8		Number of times the statement was executed
total_exec_time	float8		Total time spent executing the statement, in milliseconds
min_exec_time	float8		Minimum time spent executing the statement, in milliseconds
max_exec_time	float8		Maximum time spent executing the statement, in milliseconds
mean_exec_time	float8		Mean time spent executing the statement, in milliseconds
stddev_exec_time	float8		Population standard deviation of time spent executing the statement, in milliseconds
exec_rusage	pgpro_stats_rusage		Resource usage statistics of the statement execution.
rows	int8		Total number of rows retrieved or affected by the statement
shared_blks_hit	int8		Total number of shared block cache hits by the statement
shared_blks_read	int8		Total number of shared blocks read by the statement
shared_blks_dirtied	int8		Total number of shared blocks dirtied by the statement
shared_blks_written	int8		Total number of shared blocks written by the statement

Name	Type	References	Description
local_blks_hit	int8		Total number of local block cache hits by the statement
local_blks_read	int8		Total number of local blocks read by the statement
local_blks_dirtied	int8		Total number of local blocks dirtied by the statement
local_blks_written	int8		Total number of local blocks written by the statement
temp_blks_read	int8		Total number of temp blocks read by the statement
temp_blks_written	int8		Total number of temp blocks written by the statement
blk_read_time	float8		Total time the statement spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8		Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_read_time	float8		Total time the statement spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8		Total time the statement spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8		Total number of WAL records generated by the statement
wal_fpi	int8		Total number of WAL full page images generated by the statement

Name	Type	References	Description
wal_bytes	numeric		Total amount of WAL bytes generated by the statement
jit_functions	int8		Total number of functions JIT-compiled by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8		Total time spent by the statement on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8		Number of times functions used in the statement have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8		Total time spent by the statement on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8		Number of times the statement has been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8		Total time spent by the statement on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8		Number of times code has been emitted by the statement. In Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8		Total time spent by the statement on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
wait_stats	jsonb		A jsonb object containing statistics on wait events, for each execution of the query that uses the corresponding plan. Each statistic is

Name	Type	References	Description
			provided in milliseconds and is a multiple of the pgpro_stats.profile_period configuration parameter.
inval_msgs	pgpro_stats_inval_msgs		Number of cache invalidation messages by type generated by the statement (if this is supported by the server, otherwise zero).

Take into account that like [pg_stat_statements](#), `pgpro_stats` normalizes into one record those DML queries (containing `SELECT`, `INSERT`, `UPDATE`, `DELETE` and `MERGE` commands) that have equivalent structures according to some internal hash value. Being compared this way, two queries are normally considered equal if they are semantically equivalent up to constants included in the queries. All the other commands are, however, compared strictly as query texts. When the value of a constant in a query is ignored for comparison with other queries, this constant is replaced in the `pgpro_stats` output with a symbol of a parameter, such as, `$k`, where `k` is a positive integer. If a query already contains parameters, the initial value of `k` equals the number following the last number of a `$n` parameter in the original query text. If there are no parameters, the initial value of `k` equals 1. Note that sometimes hidden parameter symbols affect this numbering. For example, PL/pgSQL uses such hidden symbols to insert values of function local variables into queries, so a PL/pgSQL statement `SELECT i + 1 INTO j` will be represented as `SELECT i + $2` in the normalized query text.

`pgpro_stats` uses a similar technique to normalize plan texts. When doing so, an attempt is made to associate numbers of constants in the plan text with the corresponding numbers of constants in the query text. If such an attempt appears unsuccessful for a certain constant in the plan text, it is assigned the number following the maximum number of a constant replaced in the query text. For example, consider the query:

```
SELECT 1::int, 'abc'::VARCHAR(3), 2::int;
```

`pgpro_stats` will replace numbers of constants in the query text and in the text of the corresponding plan as follows:

```
postgres=# SELECT query, plan FROM pgpro_stats_statements;
               query                               |                               plan
-----
+-----
SELECT $1::int, $2::VARCHAR(3), $3::int          | Result
      +                                           |
                                           |   Output: $1, $4, $3
      +                                           |
```

In this plan text, it appeared possible to associate constants numbered 1 and 3 from the query text, but not the constant numbered 2, and the latter was replaced with the number following the maximum number in the query text, that is, number 4.

Replacement of numbers in plan texts has an exception for version numbers of XML documents. If in the original query such a number is represented with a constant, e.g., `'1.0'`, it is retained as is in the plan text rather than replaced with `$k`. If the version number of an XML document is represented with an expression, replacement of constants follows usual rules.

F.43.4.2. The `pgpro_stats_totals` View

The aggregate statistics gathered by the module are made available via a view named `pgpro_stats_totals`. This view contains one row for each distinct object (up to the maximum number of distinct objects that the module can track). The columns of the view are shown in [Table F.95](#).

Table F.95. pgpro_stats_totals Columns

Name	Type	Description
object_type	text	Type of the object for which aggregated statistics are collected: "cluster", "database", "user", "client_addr", "application", "backend", "session"
object_id	bigint	ID of the object: oid for databases and users, pid for backends, sid for sessions, NULL for others
object_name	text	Textual name of the object or NULL
queries_planned	int8	Number of queries planned
total_plan_time	float8	Total time spent in the planning of statements, in milliseconds
total_plan_rusage	pgpro_stats_rusage	Aggregate resource usage statistics of the statement planning
queries_executed	int8	Number of queries executed
total_exec_time	float8	Total time spent in the execution of statements, in milliseconds
total_exec_rusage	pgpro_stats_rusage	Aggregate resource usage statistics of the statement execution
rows	int8	Total number of rows retrieved or affected by the statements
shared_blks_hit	int8	Total number of shared block cache hits by the statements
shared_blks_read	int8	Total number of shared blocks read by the statements
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statements
shared_blks_written	int8	Total number of shared blocks written by the statements
local_blks_hit	int8	Total number of local block cache hits by the statements
local_blks_read	int8	Total number of local blocks read by the statements
local_blks_dirtied	int8	Total number of local blocks dirtied by the statements
local_blks_written	int8	Total number of local blocks written by the statements
temp_blks_read	int8	Total number of temp blocks read by the statements
temp_blks_written	int8	Total number of temp blocks written by the statements
blk_read_time	float8	Total time the statements spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)

Name	Type	Description
blk_write_time	float8	Total time the statements spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
temp_blk_read_time	float8	Total time the statements spent reading temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
temp_blk_write_time	float8	Total time the statements spent writing temp blocks, in milliseconds (if track_io_timing is enabled, otherwise zero). In Postgres Pro versions lower than 15, contains zero.
wal_records	int8	Total number of WAL records generated by the statements
wal_fpi	int8	Total number of WAL full page images generated by the statements
wal_bytes	numeric	Total amount of WAL bytes generated by the statements
jit_functions	int8	Total number of functions JIT-compiled by the statements. In Postgres Pro versions lower than 15, contains zero.
jit_generation_time	float8	Total time spent by the statements on generating JIT code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_count	int8	Number of times functions used in the statements have been inlined. In Postgres Pro versions lower than 15, contains zero.
jit_inlining_time	float8	Total time spent by the statements on inlining functions, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_count	int8	Number of times the statements have been optimized. In Postgres Pro versions lower than 15, contains zero.
jit_optimization_time	float8	Total time spent by the statements on optimizing, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
jit_emission_count	int8	Number of times code has been emitted by the statements. In

Name	Type	Description
		Postgres Pro versions lower than 15, contains zero.
jit_emission_time	float8	Total time spent by the statements on emitting code, in milliseconds. In Postgres Pro versions lower than 15, contains zero.
wait_stats	jsonb	A <code>jsonb</code> object containing statistics on wait events for each execution of the queries. Each statistic is provided in milliseconds and is a multiple of the <code>pgpro_stats.profile_period</code> configuration parameter.
inval_msgs	pgpro_stats_inval_msgs	Number of cache invalidation messages by type generated by the statements (if this is supported by the server, otherwise zero).
cache_resets	int4	Number of shared cache resets (only for cluster, databases and backends). Gets incremented for a backend when it receives a full cache reset message.

F.43.4.3. The `pgpro_stats_metrics` View

The metrics gathered by `pgpro_stats` are displayed in the `pgpro_stats_metrics` view. The table below describes the columns of the view.

Table F.96. `pgpro_stats_metrics` Columns

Name	Type	Description
metric_number	int4	A unique ID of the collected metric assigned by user. This ID is included into parameter names that define the metric.
metric_name	text	The name of the metric defined by the <code>pgpro_stats.metric_N_name</code> parameter
db_name	text	The name of the database for which a particular metric was collected
ts	timestampz	The time when the metric value got calculated
value	jsonb	The result of the query used for metric measurement. It is serialized in <code>jsonb</code> as an array of objects received via <code>to_jsonb(resulting_row)</code> . If an error occurs, a single object is returned that contains <code>code</code> , <code>message</code> , <code>detail</code> , and <code>hint</code> fields.

F.43.4.4. The `pgpro_stats_archiver` View

The `pgpro_stats_archiver` view will contain one row showing data about the archiver process of the cluster.

Table F.97. `pgpro_stat_archiver` Columns

Column	Type	Description
<code>archived_count</code>	<code>bigint</code>	Number of WAL files that have been successfully archived
<code>last_archived_wal</code>	<code>text</code>	Name of the last WAL file successfully archived
<code>last_archived_time</code>	<code>timestamp with time zone</code>	Time of the last successful archive operation
<code>failed_count</code>	<code>bigint</code>	Number of failed attempts for archiving WAL files
<code>last_failed_wal</code>	<code>text</code>	Name of the WAL file of the last failed archival operation
<code>last_failed_time</code>	<code>timestamp with time zone</code>	Time of the last failed archival operation
<code>active_time</code>	<code>int8</code>	Overall time that the archiver process was active
<code>archive_command_time</code>	<code>int8</code>	Overall execution time of the archive command
<code>stats_reset</code>	<code>timestamp with time zone</code>	Time at which these statistics were last reset

F.43.4.5. The `pgpro_stats_vacuum_database` View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_database` (see [System Views](#) for details).

The `pgpro_stats_vacuum_database` view will contain one row for each database in the current cluster, showing statistics about vacuuming that database. These statistics are collected by the core system as explained in [Section 27.2](#). The table below describes the columns of the view.

Table F.98. `pgpro_stats_vacuum_database` Columns

Column	Type	Description
<code>dbid</code>	<code>oid</code>	OID of a database
<code>total_blks_read</code>	<code>int8</code>	Number of database blocks read by vacuum operations performed on this database
<code>total_blks_hit</code>	<code>int8</code>	Number of times database blocks were found in the buffer cache by vacuum operations performed on this database
<code>total_blks_dirtied</code>	<code>int8</code>	Number of database blocks dirtied by vacuum operations performed on this database

Column	Type	Description
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this database
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this database
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this database
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this database
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this database, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this database, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this database, in milliseconds
user_time	float8	User CPU time of vacuuming this database, in milliseconds
total_time	float8	Total time of vacuuming this database, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this database were interrupted on any errors

F.43.4.6. The pgpro_stats_vacuum_tables View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_tables` (see [System Views](#) for details).

The `pgpro_stats_vacuum_tables` view will contain one row for each table in the current database (including TOAST tables), showing statistics about vacuuming that specific table. These statistics are collected by the core system as explained in [Section 27.2](#). The table below describes the columns of the view.

Table F.99. pgpro_stats_vacuum_tables Columns

Column	Type	Description
relid	oid	OID of a table
schema	name	Name of the schema this table is in
relname	name	Name of this table
total_blks_read	int8	Number of database blocks read by vacuum operations performed on this table
total_blks_hit	int8	Number of times database blocks were found in the buffer cache by vacuum operations performed on this table
total_blks_dirtied	int8	Number of database blocks dirtied by vacuum operations performed on this table
total_blks_written	int8	Number of database blocks written by vacuum operations performed on this table
rel_blks_read	int8	Number of blocks vacuum operations read from this table
rel_blks_hit	int8	Number of times blocks of this table were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
pages_scanned	int8	Number of pages examined by vacuum operations performed on this table
pages_removed	int8	Number of pages removed from the physical storage by vacuum operations performed on this table
pages_frozen	int8	Number of times vacuum operations marked pages of this table as all-frozen in the visibility map
pages_all_visible	int8	Number of times vacuum operations marked pages of this table as all-visible in the visibility map
tuples_deleted	int8	Number of dead tuples vacuum operations deleted from this table
tuples_frozen	int8	Number of tuples of this table that vacuum operations marked as frozen
dead_tuples	int8	Number of dead tuples vacuum operations left in this table due to their visibility in transactions

Column	Type	Description
index_vacuum_count	int8	Number of times indexes on this table were vacuumed
rev_all_frozen_pages	int8	Number of times the all-frozen mark in the visibility map was removed for pages of this table
rev_all_visible_pages	int8	Number of times the all-visible mark in the visibility map was removed for pages of this table
wal_records	int8	Total number of WAL records generated by vacuum operations performed on this table
wal_fpi	int8	Total number of WAL full page images generated by vacuum operations performed on this table
wal_bytes	numeric	Total amount of WAL bytes generated by vacuum operations performed on this table
blk_read_time	float8	Time spent reading database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this table, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this table, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this table, in milliseconds
user_time	float8	User CPU time of vacuuming this table, in milliseconds
total_time	float8	Total time of vacuuming this table, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this table were interrupted on any errors

Columns `total_*`, `wal_*` and `blk_*` include data on vacuuming indexes on this table, while columns `system_time` and `user_time` only include data on vacuuming the heap.

F.43.4.7. The `pgpro_stats_vacuum_indexes` View

Important

Starting with Postgres Pro 16, this view contains no data because the statistics to be displayed are available through the catalog view `pg_stats_vacuum_indexes` (see [System Views](#) for details).

The `pgpro_stats_vacuum_indexes` view will contain one row for each index in the current database (including TOAST table indexes), showing statistics about vacuuming that specific index. These statistics are collected by the core system as explained in [Section 27.2](#). The table below describes the columns of the view.

Table F.100. `pgpro_stats_vacuum_indexes` Columns

Column	Type	Description
<code>relid</code>	<code>oid</code>	OID of an index
<code>schema</code>	<code>name</code>	Name of the schema this index is in
<code>relname</code>	<code>name</code>	Name of this index
<code>total_blks_read</code>	<code>int8</code>	Number of database blocks read by vacuum operations performed on this index
<code>total_blks_hit</code>	<code>int8</code>	Number of times database blocks were found in the buffer cache by vacuum operations performed on this index
<code>total_blks_dirtied</code>	<code>int8</code>	Number of database blocks dirtied by vacuum operations performed on this index
<code>total_blks_written</code>	<code>int8</code>	Number of database blocks written by vacuum operations performed on this index
<code>rel_blks_read</code>	<code>int8</code>	Number of blocks vacuum operations read from this index
<code>rel_blks_hit</code>	<code>int8</code>	Number of times blocks of this index were already found in the buffer cache by vacuum operations, so that a read was not necessary (this only includes hits in the Postgres Pro buffer cache, not the operating system's file system cache)
<code>pages_deleted</code>	<code>int8</code>	Number of pages deleted by vacuum operations performed on this index
<code>tuples_deleted</code>	<code>int8</code>	Number of dead tuples vacuum operations deleted from this index
<code>wal_records</code>	<code>int8</code>	Total number of WAL records generated by vacuum operations performed on this index
<code>wal_fpi</code>	<code>int8</code>	Total number of WAL full page images generated by vacuum operations performed on this index
<code>wal_bytes</code>	<code>numeric</code>	Total amount of WAL bytes generated by vacuum operations performed on this index
<code>blk_read_time</code>	<code>float8</code>	Time spent reading database blocks by vacuum operations performed on this index, in mil-

Column	Type	Description
		liseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time	float8	Time spent writing database blocks by vacuum operations performed on this index, in milliseconds (if track_io_timing is enabled, otherwise zero)
delay_time	float8	Time spent sleeping in a vacuum delay point by vacuum operations performed on this index, in milliseconds (see Section 19.4.4 for details)
system_time	float8	System CPU time of vacuuming this index, in milliseconds
user_time	float8	User CPU time of vacuuming this index, in milliseconds
total_time	float8	Total time of vacuuming this index, in milliseconds
interrupts	int4	Number of times vacuum operations performed on this index were interrupted on any errors

F.43.5. Data Types

F.43.5.1. The `pgpro_stats_rusage` Type

`pgpro_stats_rusage` is a record type that contains resource usage statistics of statement planning/execution. The fields of this type are shown in [Table F.101](#).

Table F.101. `pgpro_stats_rusage` Fields

Name	Type	Description
reads	bigint	Number of bytes read by the filesystem layer
writes	bigint	Number of bytes written by the filesystem layer
user_time	double precision	User CPU time used
system_time	double precision	System CPU time used
minflts	bigint	Number of page reclaims (soft page faults)
majflts	bigint	Number of page faults (hard page faults)
nswaps	bigint	Number of swaps
msgsnds	bigint	Number of IPC messages sent
msgrcv	bigint	Number of IPC messages received
nsignals	bigint	Number of signals received
nvcsws	bigint	Number of voluntary context switches
nivcsws	bigint	Number of involuntary context switches

F.43.6. Functions

`pgpro_stats_statements_reset(userid Oid, dbid Oid, queryid bigint, planid bigint)` returns `void`

`pgpro_stats_statements_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified `userid`, `dbid`, `queryid`, and `planid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

Note

As statistics in the `pgpro_stats_vacuum_database`, `pgpro_stats_vacuum_tables`, and `pgpro_stats_vacuum_indexes` views are collected by the core system, to reset them, call the `pg_stat_reset()` function (see [Section 27.2.23](#) for details).

`pgpro_stats_statements(showtext boolean)` returns `setof record`

The `pgpro_stats_statements` view is defined in terms of a function also named `pgpro_stats_statements`. Users can also call the `pgpro_stats_statements` function directly, and by specifying `showtext := false` make query text be omitted (that is, the `OUT` argument that corresponds to the view's `query` column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pgpro_stats` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pgpro_stats_statements` data.

`pgpro_stats_totals_reset(type text, id bigint)` returns `void`

`pgpro_stats_totals_reset` discards statistics gathered so far by `pgpro_stats` corresponding to the specified object `type` and `id`. If no parameter is specified or the `type` parameter is set to 0, all statistics will be discarded. If `type` is set to a valid object type, then if `id` is specified, then statistics will be discarded only for the specified object, else, statistics will be discarded for all objects of the specified type. Otherwise, no statistics will be discarded. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pgpro_stats_totals()` returns `setof record`

The `pgpro_stats_totals` view is defined in terms of a function also named `pgpro_stats_totals`. Users can also call the `pgpro_stats_totals` function directly.

`pgpro_stats_metrics(showtext boolean)` returns `setof record`

Defines the `pgpro_stats_metrics` view, which is described in detail in [Table F.96](#).

`pgpro_stats_wal_sender_crc_errors()` returns `bigint`

`pgpro_stats_wal_sender_crc_errors` returns the number of errors detected by the WAL sender process when the [wal_sender_check_crc](#) parameter is on. Note that this counter is reset to zero when the cluster restarts.

`pgpro_stats_vacuum_tables(dboid oid, relid oid)` returns `setof record`

Defines the row of the `pgpro_stats_vacuum_tables` view, which is described in detail in [Table F.99](#), for the database specified by `dboid` and table specified by `relid`. If `relid = 0`, the statistics for each table in the specified database are returned.

`pgpro_stats_vacuum_indexes(dboid oid, relid oid)` returns setof record

Defines the row of the `pgpro_stats_vacuum_indexes` view, which is described in detail in [Table F.100](#), for the database specified by `dboid` and index specified by `relid`. If `relid = 0`, the statistics for each index in the specified database are returned.

F.43.6.1. Session-Tracing Functions

In `pgpro_stats`, tracing of application sessions is implemented. It is based on filters, which trigger logging the execution of queries that match filtering conditions. Queries and their plans are logged in so called *trace files* specified by the user or in the system log file (if the trace file is not specified). Filters are stored in a table located in the shared memory. The rows of this table are filters, and the columns contain filtering conditions. You should fill this table with filters to start tracing queries.

Once a database administrator adds a filter in any session, all subsequent executions of queries that match the filter conditions will be traced by all sessions of the instance without a need in the server restart. In other words, filters can be added, deleted or updated “on the fly”, and tracing with these filters immediately starts for existing and future sessions.

Each filter includes:

- Identification fields, such as `username`, `client_addr`, `database_name`, `pid` or `application_name` (see [Table F.102](#) for details). Execution of a statement will be traced if its characteristics in the current session are the same as the values of the respective filter identification fields.
- Resource fields, from `duration` to `total_inval_msgs` in [Table F.102](#). Execution of a statement will be traced if the resource statistics of the statement execution in the current session are not less than the limits specified in the respective filter resource fields.
- Fields specifying `EXPLAIN` options. They allow you to control the `EXPLAIN` output to the trace file or system log file.

Warning

Although when specifying a filter, you can assign values to any combination of filter fields, bear in mind that a too general filter will lead to an excessive size of the trace file and will affect the performance more than desired as the main performance overhead is associated with writing to the trace file rather than with checking the filter conditions.

Specialized functions enable creation, update and deletion of query filters:

`pgpro_stats_trace_insert(VARIADIC "any")` returns integer

Adds a filter to the list of session-tracing filters. A filter must be passed as a sequence of alternating key and value pairs. For example:

```
pgpro_stats_trace_insert('pid', 42, 'database', 'main', 'explain_analyze', true)
```

See [Table F.102](#) for the list of available filters. NULL values are not allowed, so just omit fields that can take any value. Returns → `filter_id` of the added filter.

`pgpro_stats_trace_update(filter_id integer, VARIADIC "any")` returns boolean

Updates a session-tracing filter defined by `filter_id`. Filter fields to update must be passed as a sequence of alternating key and value pairs. NULL values are accepted. See [Table F.102](#) for the list of available filters. Returns true on success, false otherwise.

`pgpro_stats_trace_delete(filter_id integer)` returns boolean

Deletes a session-tracing filter defined by `filter_id`. Returns true on success, false otherwise.

`pgpro_stats_trace_reset()` returns integer

Removes all session-tracing filters. Returns the number of removed filters.

`pgpro_stats_trace_show()` returns setof record

Displays all the query filters that the user added for tracing. These filters are shown in [Table F.102](#).

Table F.102. `pgpro_stats_trace_show()` Output

Name	Type	Description
<code>filter_id</code>	integer	Filter ID, numbered from 1.
<code>active</code>	boolean	True if the filter is active. Default: true.
<code>alias</code>	name	Filter name
<code>tracefile</code>	name	Name of the trace file. Trace files are created in <code>PGDATA/pg_stat</code> directory and have <code>trace</code> extensions.
<code>pid</code>	integer	Process ID of the backend that executes a particular statement
<code>database_name</code>	name	Name of the database where a particular statement is executed
<code>client_addr</code>	name	IP address of the client connected to this backend
<code>application_name</code>	name	Name of the application that invoked execution of the statement
<code>username</code>	name	Name of the user who executes the statement
<code>queryid</code>	bigint	Internal hash code, computed from the statement's parse tree
<code>planid</code>	bigint	Internal hash code, computed from the statement's plan tree
<code>duration</code>	float8	Time spent in the planning and execution of the statement, in milliseconds
<code>plan_time</code>	float8	Time spent in the planning of the statement, in milliseconds
<code>exec_time</code>	float8	Time spent in the execution of the statement, in milliseconds
<code>user_time</code>	float8	User CPU time used in planning and execution of the statement
<code>system_time</code>	float8	System CPU time used in planning and execution of the statement
<code>rows</code>	int8	Total number of rows retrieved or affected by the statement
<code>shared_blks_hit</code>	int8	Total number of shared block cache hits by the statement
<code>shared_blks_read</code>	int8	Total number of shared blocks read by the statement
<code>shared_blks_fetched</code>	int8	Total number of shared blocks fetched from buffers by the statement

Name	Type	Description
shared_blks_dirtied	int8	Total number of shared blocks dirtied by the statement
shared_blks_written	int8	Total number of shared blocks written by the statement
local_blks_hit	int8	Total number of local block cache hits by the statement
local_blks_read	int8	Total number of local blocks read by the statement
local_blks_fetched	int8	Total number of local blocks fetched from buffers by the statement
local_blks_dirtied	int8	Total number of local blocks dirtied by the statement
local_blks_written	int8	Total number of local blocks written by the statement
temp_blks_read	int8	Total number of temp blocks read by the statement
temp_blks_written	int8	Total number of temp blocks written by the statement
wal_bytes	numeric	Total amount of WAL bytes generated by the statement
total_wait_time	float8	Total time execution of this statement spent waiting
total_inval_msgs	bigint	Total number of cache invalidation messages generated by the statement (if this is supported by the server)
explain_analyze	boolean	If true, EXPLAIN output will be logged with ANALYZE parameter. Default: false.
explain_verbose	boolean	If true, EXPLAIN output will be logged with VERBOSE parameter. Default: false.
explain_costs	boolean	If true, EXPLAIN output will be logged with COSTS parameter. Default: true.
explain_settings	boolean	If true, EXPLAIN output will be logged with SETTINGS parameter. Default: false.
explain_buffers	boolean	If true, EXPLAIN output will be logged with BUFFERS parameter. Default: false.
explain_wal	boolean	If true, EXPLAIN output will be logged with WAL parameter. Default: false.
explain_timing	boolean	If true, EXPLAIN output will be logged with TIMING parameter. Default: false.

Name	Type	Description
explain_format	text	The value of <code>FORMAT</code> parameter of <code>EXPLAIN</code> to be logged, which can be TEXT, XML, JSON, or YAML. Default: TEXT

Example F.4. Usage of Session-Tracing Functions

Let's add the filter first:

```
SELECT pgpro_stats_trace_insert('alias', 'first', 'pid', pg_backend_pid(),
    'explain_analyze', true);
```

Let's add the filter second and specify logging to the trace file `second_tf.trace`:

```
SELECT pgpro_stats_trace_insert('alias', 'second', 'database_name', current_database(),
    'explain_costs', false, 'tracefile', 'second_tf');
```

You can view the table with filters as follows:

```
\x auto
SELECT * from pgpro_stats_trace_show();
```

```
-[ RECORD 1 ]-----+-----
filter_id      | 1
active         | t
alias          | first
tracefile      |
pid            | 243183
database_name  |
client_addr    |
application_name |
username       |
queryid        |
planid         |
duration       |
plan_time      |
exec_time      |
user_time      |
system_time    |
rows           |
shared_blks_hit |
shared_blks_read |
shared_blks_fetched |
shared_blks_dirtied |
shared_blks_written |
local_blks_hit |
local_blks_read |
local_blks_fetched |
local_blks_dirtied |
local_blks_written |
temp_blks_read |
temp_blks_written |
wal_bytes      |
total_wait_time |
total_inval_msgs |
explain_analyze | t
explain_verbose | f
explain_costs   | t
explain_settings | f
```

explain_buffers	f
explain_wal	f
explain_timing	t
explain_format	text
-[RECORD 2]-----+-----	
filter_id	2
active	t
alias	second
tracefile	second_tf
pid	
database_name	postgres
client_addr	
application_name	
username	
queryid	
planid	
duration	
plan_time	
exec_time	
user_time	
system_time	
rows	
shared_blks_hit	
shared_blks_read	
shared_blks_fetched	
shared_blks_dirtied	
shared_blks_written	
local_blks_hit	
local_blks_read	
local_blks_fetched	
local_blks_dirtied	
local_blks_written	
temp_blks_read	
temp_blks_written	
wal_bytes	
total_wait_time	
total_inval_msgs	
explain_analyze	f
explain_verbose	f
explain_costs	f
explain_settings	f
explain_buffers	f
explain_wal	f
explain_timing	f
explain_format	text

The following query matches the conditions of both filters, so it must be logged in the system log file and in the specified trace file:

```
SELECT 1 as result;
```

The following is the output to the system log file:

```
2023-04-18 04:52:53.242 MSK [63112] LOG:  Filter 1 triggered explain of the plan:
Query Text: SELECT 1 as result;
Result  (cost=0.00..0.01 rows=1 width=4) (actual time=0.003..0.003 rows=1 loops=1)
```

And the following is the output to the `second_tf.trace` trace file:

```
Query Text: SELECT 1 as result;
Result
```

Let's delete the first filter:

```
SELECT pgpro_stats_trace_delete(1);
```

Let's also change `pid` to 2 for the second filter

```
SELECT pgpro_stats_trace_update(2, 'pid', 2);
```

When you execute the query

```
SELECT 2 as result;
```

it does not get logged to `second_tf.trace`.

Now let's remove all filters from the table:

```
SELECT pgpro_stats_trace_reset();
```

F.43.6.2. Functions for Creating Views that Emulate Other Extensions

`pgpro_stats` can create views similar to those available in [pg_stat_statements](#) and [pg_stat_kcache](#) extensions. Specifically, [pg_stat_statements](#), `pg_stat_statements_info`, `pg_stat_kcache` and `pg_stat_kcache_detail` views can be created. Each view is only created in a Postgres Pro version if it is available in `pg_stat_statements/pg_stat_kcache` extension for the same version of Postgres Pro/PostgreSQL. For example, the `pg_stat_statements_info` view is only created in Postgres Pro versions starting with 14. The following functions enable creating these views:

```
pgpro_stats_create_pg_stat_statements_compatible_views() returns void
```

Creates `pg_stat_statements` and `pg_stat_statements_info` views.

```
pgpro_stats_create_pg_stat_kcache_compatible_views() returns void
```

Creates `pg_stat_kcache` and `pg_stat_kcache_detail` views.

Only superuser can call these functions.

To create `pg_stat_statements*` views, drop the `pg_stat_statements` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_statements_compatible_views();
```

To create `pg_stat_kcache*` views, drop the `pg_stat_kcache` extension if it was previously installed and call the function:

```
select pgpro_stats_create_pg_stat_kcache_compatible_views();
```

Once the views are created, you can work with them as if the `pg_stat_statements/pg_stat_kcache` extension is installed.

If you need to remove the views created earlier, do it in a regular way:

```
drop view pg_stat_statements;
drop view pg_stat_statements_info;
drop view pg_stat_kcache;
drop view pg_stat_kcache_detail;
```

F.43.7. Configuration Parameters

F.43.7.1. General Settings

`pgpro_stats.max (integer)`

`pgpro_stats.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_statements` view). If more distinct statements than that are

observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`pgpro_stats.max_totals` (integer)

`pgpro_stats.max_totals` is the maximum number of objects tracked by the module (i.e., the maximum number of rows in the `pgpro_stats_totals` view). If more distinct objects than that are observed, information about least-used objects is discarded. The default value is 1000. This parameter can only be set at server start.

`pgpro_stats.track` (enum)

`pgpro_stats.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions) with nesting level not greater than 100, or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pgpro_stats.track_utility` (boolean)

`pgpro_stats.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_planning` (boolean)

`pgpro_stats.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pgpro_stats.track_totals` (boolean)

`pgpro_stats.track_totals` controls whether aggregate statistics for objects (cluster, users, databases etc.) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_cluster` (boolean)

`pgpro_stats.track_cluster` controls whether aggregate statistics for the cluster are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_databases` (boolean)

`pgpro_stats.track_databases` controls whether aggregate statistics for the databases are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_users` (boolean)

`pgpro_stats.track_users` controls whether aggregate statistics for the users are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_applications` (boolean)

`pgpro_stats.track_applications` controls whether aggregate statistics for the applications (whose names are set by [application_name](#)) are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_client_addr` (boolean)

`pgpro_stats.track_client_addr` controls whether aggregate statistics for the client IP addresses are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_backends` (boolean)

`pgpro_stats.track_backends` controls whether aggregate statistics for the backends are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.track_sessions` (boolean)

`pgpro_stats.track_sessions` controls whether aggregate statistics for the sessions are tracked by the module. The default value is `on`. Only superusers can change this setting.

`pgpro_stats.save` (boolean)

`pgpro_stats.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are neither saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

`pgpro_stats.plan_format` (text)

`pgpro_stats.plan_format` selects the `EXPLAIN` format for the query plan. Possible values are `text`, `xml`, `json`, and `yaml`. The default value is `text`. Changing this parameter requires a server restart.

`pgpro_stats.enable_profile` (boolean)

`pgpro_stats.enable_profile` enables sampling of wait events for separate statements. The default value is `true`. Changing this parameter requires a server restart.

`pgpro_stats.query_sample_rate` (float)

`pgpro_stats.query_sample_rate` specifies the fraction of queries that are randomly selected for statistics calculation. Possible values lie between `0.0` (no queries) and `1.0` (all queries). The default value is `1.0`. Changing this parameter requires a server restart.

`pgpro_stats.profile_period` (integer)

`pgpro_stats.profile_period` specifies the period, in milliseconds, during which to sample wait events. The default value is `10`. Only superusers can change this setting.

`pgpro_stats.metrics_buffer_size` (integer)

`pgpro_stats.metrics_buffer_size` specifies the size of the ring buffer used for collecting statistical metrics. The default value is `16kB`. Changing this parameter requires a server restart.

`pgpro_stats.metrics_workers` (integer)

`pgpro_stats.metrics_workers` specifies the number of workers used to collect statistical metrics. If this parameter is set to `2` or higher, one of the workers serves as the master worker distributing queries to other workers. If only one worker is available, it gets reloaded to connect to different databases. Setting this parameter to `0` disables metrics collection. The default value is `2`. Changing this parameter requires a server restart.

`pgpro_stats.stats_temp_directory` (string)

`pgpro_stats.stats_temp_directory` specifies the directory with the external file to store query texts. This can be a path relative to the data directory or an absolute path. Changing this parameter requires a server restart.

F.43.7.2. Metrics Settings

The following parameters can be used to define a custom metric to collect. The `N` placeholder in the parameter name serves as a unique identifier of the metric to which this setting should apply; it must be set to a non-negative integer for each metric.

When you add these parameters for a new metric, you have to restart the server for the changes to take effect. Once the new metric is added, its parameters can be changed without a server restart by simply reloading the `postgresql.conf` configuration file.

`pgpro_stats.metric_N_name` (text)

The name of metric *N*. This name will be displayed in the `metric_name` column of the `pgpro_stats_metrics` view.

`pgpro_stats.metric_N_query` (text)

The query statement that defines the metric to collect.

`pgpro_stats.metric_N_period` (integer)

The time interval at which to collect metric *N*, in milliseconds. Default: 60000 ms

`pgpro_stats.metric_N_db` (text)

The list of databases for which to collect metric *N*. Database names must be separated by commas. You can specify the `*` character to select all databases in the cluster except the template databases. If you need to analyze the template databases as well, you have to specify them explicitly.

`pgpro_stats.metric_N_user` (text)

The name of the user on behalf of which to collect metric *N*. This user must have access to the database for which the metric is collected.

F.43.8. Cache Invalidation Metrics

Among the rest, `pgpro_stats` can collect cache invalidation statistics. This section provides some background information needed to better understand related metrics.

Each backend has its local cache, which allows you to minimize accesses for meta information on tables, for example, to the system catalogs. If a backend changes the meta information, this information must be updated in other backends' caches. This is implemented by sending invalidation messages through a queue: the backend that changed the meta information on some object sends an appropriate message to the queue.

All backends get invalidation messages from the queue. Depending on whether the object for which the invalidation message was received is cached, the backend either ignores the message (when the object is not cached) or updates its cache (when the object is cached). In `pgpro_stats`, most invalidation message counters, unless explicitly stated otherwise for certain counters, are incremented when backends just generate messages, which will only be sent to the queue upon commit of the appropriate transaction. Note that the counters will remain incremented if the transaction is rolled back, although the message will not be sent to the queue.

When a backend that is adding messages to the queue figures out that the queue size reached a certain limit, it starts a cleanup by deleting messages already processed by all backends, and if backends are found that heavily fall behind and thus delay the cleanup, they get a reset signal, which forces them to reset all their caches.

F.43.8.1. The `pgpro_stats_inval_status` View

The `pgpro_stats_inval_status` view shows one row with the current status of the cache invalidation global queue. The columns of the view are shown in [Table F.103](#).

Table F.103. `pgpro_stats_inval_status` Columns

Name	Type	Description
<code>num_inval_messages</code>	<code>int8</code>	Current number of invalidation messages in the queue
<code>num_inval_queue_cleanups</code>	<code>int8</code>	Number of invalidation queue cleanups done to prevent its overflow

Name	Type	Description
num_inval_queue_resets	int4	Number of cache resets for backends that fail to process messages fast enough

In a working system, `num_inval_messages` usually approximately equals 4000, which means that the queue is pretty full. The speed of the `num_inval_queue_cleanups` growth is determined by how fast invalidation messages are generated. Growth of `num_inval_queue_resets` is normally zero, and non-zero growth indicates either too fast generation of messages or delays in processing messages by backends. Monitoring `num_inval_queue_cleanups` and `num_inval_queue_resets` may in some cases allow you to detect problematic backend/backends as described below.

If for a certain time interval, `num_inval_queue_cleanups` considerably increased, while `num_inval_queue_resets` did not, this indicates that invalidation messages are generated faster and/or backends process them more slowly, but backends still manage to process messages before the queue overflows.

If for a time interval, `num_inval_queue_cleanups` did not considerably increase, while `num_inval_queue_resets` did, this definitely indicates a delay in processing messages by backend(s), and the `cache_resets` column of the `pgpro_stats_totals` view allows you to figure out which backend(s) to blame.

If for a time interval, both counters considerably increased, this also indicates that invalidation messages are generated faster and/or backends process them more slowly, but this time backends fail to process messages before the queue overflows. The `cache_resets` column of the `pgpro_stats_totals` view allows you detect which backend(s) delay message processing. In this case, it is not possible to definitely conclude whether too fast generation of messages or a delay in message processing accounts for the growth of `num_inval_queue_resets`. However, the `totals` counter of the `pgpro_stats_inval_msgs` view may help here. If the change of this counter for that interval is pretty the same as for a previous interval of the same length, you can definitely conclude that the growth is caused by backend delays.

F.43.8.2. The `pgpro_stats_inval_msgs` Type

The `pgpro_stats_statements` and `pgpro_stats_totals` views for each corresponding object, show a record of the `pgpro_stats_inval_msgs` record type containing counters for cache invalidation messages. The fields of the type are shown in Table F.104.

Table F.104. `pgpro_stats_inval_msgs` Fields

Name	Type	Description
total	bigint	Total number of invalidation messages
catcache	bigint	Number of selective catalog cache invalidation messages
catalog	bigint	Number of whole catalog cache invalidation messages
relcache	bigint	Number of selective relation cache invalidation messages
relcache_all	bigint	Number of whole relation cache invalidation messages
smgr	bigint	Number of invalidation messages of open relation files. Gets incremented when the messages are sent to the queue.
relmap	bigint	Number of relation map cache invalidation messages. Gets in-

Name	Type	Description
		cremented when the messages are sent to the queue.
snapshot	bigint	Number of catalog snapshot invalidation messages

Postgres Professional, Moscow, Russia

F.44. pg_query_state

The `pg_query_state` module provides facility to know the current state of query execution on working backend.

F.44.1. Overview

Each non-utility query statement (SELECT/INSERT/UPDATE/DELETE) after optimization/planning stage is translated into plan tree, which is kind of imperative representation of declarative SQL query. EXPLAIN ANALYZE request allows to demonstrate execution statistics gathered from each node of plan tree (full time of execution, number of rows emitted to upper nodes, etc). But this statistics is collected after execution of query. This module allows to show actual statistics of query running on external backend. At that, format of resulting output is almost identical to ordinal EXPLAIN ANALYZE. Thus users are able to track of query execution in progress. In fact, this module is able to explore external backend and determine its actual state. Particularly it's helpful when backend executes a heavy query or gets stuck.

F.44.2. Use cases

Using this module there can help in the following things:

- detect a long query (along with other monitoring tools);
- supervise query execution.

F.44.3. Installation

To install `pg_query_state` run in `psql`:

```
CREATE EXTENSION pg_query_state;
```

Then modify `shared_preload_libraries` parameter in `postgres.conf` as following:

```
shared_preload_libraries = 'pg_query_state'
```

It will require to restart the Postgres Pro instance.

F.44.4. Function `pg_query_state`

```
pg_query_state(integer pid,
                verbose boolean DEFAULT FALSE,
                costs   boolean DEFAULT FALSE,
                timing   boolean DEFAULT FALSE,
                buffers  boolean DEFAULT FALSE,
                triggers boolean DEFAULT FALSE,
                format   text    DEFAULT 'text')
returns TABLE (pid integer,
                frame_number integer,
                query_text text,
```

```
plan text,  
leader_pid integer)
```

Extract current query state from backend with specified `pid`. Since parallel query can spawn multiple workers and function call causes nested subqueries so that state of execution may be viewed as stack of running queries, return value of `pg_query_state` has type `TABLE (pid integer, frame_number integer, query_text text, plan text, leader_pid integer)`. It represents tree structure consisting of leader process and its spawned workers identified by `pid`. Each worker refers to leader through `leader_pid` column. For leader process the value of this column is `null`. The state of each process is represented as stack of function calls. Each frame of that stack is specified as correspondence between `frame_number` starting from zero, `query_text` and `plan` with online statistics columns.

Thus, user can see the states of main query and queries generated from function calls for leader process and all workers spawned from it.

In process of execution some nodes of plan tree can take loops of full execution. Therefore statistics for each node consists of two parts: average statistics for previous loops just like in `EXPLAIN ANALYZE` output and statistics for current loop if node have not finished.

Optional arguments:

- `verbose` - use `EXPLAIN VERBOSE` for plan printing;
- `costs` - costs for each node;
- `timing` - print timing data for each node, if collecting of timing statistics is turned off on called side resulting output will contain `WARNING message timing statistics disabled`;
- `buffers` - print buffers usage, if collecting of buffers statistics is turned off on called side resulting output will contain `WARNING message buffers statistics disabled`;
- `triggers` - include triggers statistics in result plan trees;
- `format` - `EXPLAIN` format to be used for plans printing, possible values: `text`, `xml`, `json`, `yaml`.

If callable backend is not executing any query the function prints `INFO` message about backend's state taken from `pg_stat_activity` view if it exists there.

Calling role have to be superuser or member of the role whose backend is being called. Otherwise function prints `ERROR` message `permission denied`.

F.44.5. Configuration settings

There are several user-accessible GUC variables designed to toggle the whole module and the collecting of specific statistic parameters while query is running:

- `pg_query_state.enable` - disable (or enable) `pg_query_state` completely, default value is `true`
- `pg_query_state.enable_timing` - collect timing data for each node, default value is `false`
- `pg_query_state.enable_buffers` - collect buffers usage, default value is `false`

These parameters are set on called side before running any queries whose states are attempted to extract. `WARNING`: if `pg_query_state.enable_timing` is turned off the calling side cannot get time statistics, similarly for `pg_query_state.enable_buffers` parameter.

F.44.6. Examples

Set maximum number of parallel workers on `gather` node equals 2:

```
postgres=# set max_parallel_workers_per_gather = 2;
```

Assume one backend with `pid = 49265` performs a simple query:

```
postgres=# select pg_backend_pid();
```

pg_backend_pid

```
-----
      49265
(1 row)
postgres=# select count(*) from foo join bar on foo.c1=bar.c1;
```

Other backend can extract intermediate state of execution that query:

```
postgres=# \x
postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select count(*) from foo join bar on foo.c1=bar.c1;
plan         | Finalize Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |   -> Gather (Current loop: actual rows=0, loop number=1)
              |
              |         Workers Planned: 2
              |
              |         Workers Launched: 2
              |
              |   -> Partial Aggregate (Current loop: actual rows=0, loop
number=1)          |
              |         -> Nested Loop (Current loop: actual rows=12, loop
number=1)          |
              |               Join Filter: (foo.c1 = bar.c1)
              |               Rows Removed by Join Filter: 5673232
              |   -> Parallel Seq Scan on foo (Current loop: actual
rows=12, loop number=1)
              |   -> Seq Scan on bar (actual rows=500000 loops=11)
              | (Current loop: actual rows=173244, loop number=12)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
pid          | 49324
frame_number | 0
query_text   | <parallel query>
plan         | Partial Aggregate (Current loop: actual rows=0, loop number=1)
              |
              |   -> Nested Loop (Current loop: actual rows=10, loop number=1)
              |
              |         Join Filter: (foo.c1 = bar.c1)
              |         Rows Removed by Join Filter: 4896779
              |   -> Parallel Seq Scan on foo (Current loop: actual rows=10, loop
number=1)          |
              |   -> Seq Scan on bar (actual rows=500000 loops=9) (Current loop:
actual rows=396789, loop number=10)
leader_pid   | 49265
-[ RECORD
  3 ]+-----
pid          | 49323
frame_number | 0
```

```

query_text | <parallel query>
plan       | Partial Aggregate (Current loop: actual rows=0, loop number=1)
          +
          | -> Nested Loop (Current loop: actual rows=11, loop number=1)
          +
          |         Join Filter: (foo.c1 = bar.c1)
          +
          |         Rows Removed by Join Filter: 5268783
          +
          |         -> Parallel Seq Scan on foo (Current loop: actual rows=11, loop
number=1)
          +
          |         -> Seq Scan on bar (actual rows=500000 loops=10) (Current loop:
actual rows=268794, loop number=11)
leader_pid | 49265

```

In example above working backend spawns two parallel workers with pids 49324 and 49323. Their leader_pid column's values clarify that these workers belong to the main backend. Seq Scan node has statistics on passed loops (average number of rows delivered to Nested Loop and number of passed loops are shown) and statistics on current loop. Other nodes has statistics only for current loop as this loop is first (loop number = 1).

Assume first backend executes some function:

```
postgres=# select n_join_foo_bar();
```

Other backend can get the follow output:

```

postgres=# select * from pg_query_state(49265);
-[ RECORD
  1 ]+-----
pid          | 49265
frame_number | 0
query_text   | select n_join_foo_bar();
plan         | Result (Current loop: actual rows=0, loop number=1)
leader_pid   | (null)
-[ RECORD
  2 ]+-----
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | Result (Current loop: actual rows=0, loop number=1)
          +
          |   InitPlan 1 (returns $0)
          +
          |   -> Aggregate (Current loop: actual rows=0, loop number=1)
          +
          |   -> Nested Loop (Current loop: actual rows=51, loop number=1)
          +
          |         Join Filter: (foo.c1 = bar.c1)
          +
          |         Rows Removed by Join Filter: 51636304
          +
          |         -> Seq Scan on bar (Current loop: actual rows=52, loop
number=1)
          +
          |         -> Materialize (actual rows=1000000 loops=51) (Current
loop: actual rows=636355, loop number=52)+
          |         -> Seq Scan on foo (Current loop: actual
rows=1000000, loop number=1)

```

```
leader_pid    | (null)
```

First row corresponds to function call, second - to query which is in the body of that function.

We can get result plans in different format (e.g. json):

```
postgres=# select * from pg_query_state(pid := 49265, format := 'json');
-[ RECORD 1 ]+-----+
pid          | 49265
frame_number | 0
query_text   | select * from n_join_foo_bar();
plan         | {
              |   "Plan": {
              |     "Node Type": "Function Scan",
              |     "Parallel Aware": false,
              |     "Function Name": "n_join_foo_bar",
              |     "Alias": "n_join_foo_bar",
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     }
              |   }
              | }
leader_pid   | (null)
-[ RECORD 2 ]+-----+
pid          | 49265
frame_number | 1
query_text   | SELECT (select count(*) from foo join bar on foo.c1=bar.c1)
plan         | {
              |   "Plan": {
              |     "Node Type": "Result",
              |     "Parallel Aware": false,
              |     "Current loop": {
              |       "Actual Loop Number": 1,
              |       "Actual Rows": 0
              |     },
              |   "Plans": [
              |     {
              |       "Node Type": "Aggregate",
              |       "Strategy": "Plain",
              |       "Partial Mode": "Simple",
              |       "Parent Relationship": "InitPlan",
              |       "Subplan Name": "InitPlan 1 (returns $0)",
              |       "Parallel Aware": false,
              |       "Current loop": {
              |         "Actual Loop Number": 1,
              |         "Actual Rows": 0
              |       },
              |     },
              |     "Plans": [
              |       {
              |         "Node Type": "Nested Loop",
              |         "Parent Relationship": "Outer",
              |         "Parallel Aware": false,
              |         "Join Type": "Inner",
              |         "Current loop": {
              |           "Actual Loop Number": 1,
              |           "Actual Rows": 610
              |         }
              |       }
              |     ]
              |   }
              | }
```

The parameter is the name of a table. The result is a set of records, with one row for each locked row within the table. The output columns are shown in [Table F.105](#).

Table F.105. pgrowlocks Output Columns

Name	Type	Description
locked_row	tid	Tuple ID (TID) of locked row
locker	xid	Transaction ID of locker, or multixact ID if multitransaction
multi	boolean	True if locker is a multitransaction
xids	xid[]	Transaction IDs of lockers (more than one if multitransaction)
modes	text[]	Lock mode of lockers (more than one if multitransaction), an array of Key Share, Share, For No Key Update, No Key Update, For Update, Update.
pids	integer[]	Process IDs of locking backends (more than one if multitransaction)

`pgrowlocks` takes `AccessShareLock` for the target table and reads each row one by one to collect the row locking information. This is not very speedy for a large table. Note that:

1. If an `ACCESS EXCLUSIVE` lock is taken on the table, `pgrowlocks` will be blocked.
2. `pgrowlocks` is not guaranteed to produce a self-consistent snapshot. It is possible that a new row lock is taken, or an old lock is freed, during its execution.

`pgrowlocks` does not show the contents of locked rows. If you want to take a look at the row contents at the same time, you could do something like this:

```
SELECT * FROM accounts AS a, pgrowlocks('accounts') AS p
WHERE p.locked_row = a.ctid;
```

Be aware however that such a query will be very inefficient.

F.45.2. Sample Output

```
=# SELECT * FROM pgrowlocks('t1');
locked_row | locker | multi | xids | modes | pids
-----+-----+-----+-----+-----+-----
(0,1)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,2)      | 609   | f     | {609} | {"For Share"} | {3161}
(0,3)      | 607   | f     | {607} | {"For Update"} | {3107}
(0,4)      | 607   | f     | {607} | {"For Update"} | {3107}
(4 rows)
```

F.46. pg_stat_statements

The `pg_stat_statements` module provides a means for tracking planning and execution statistics of all SQL statements executed by a server.

The module must be loaded by adding `pg_stat_statements` to `shared_preload_libraries` in `postgresql.conf`, because it requires additional shared memory. This means that a server restart is needed to add or remove the module.

When `pg_stat_statements` is loaded, it tracks statistics across all databases of the server. To access and manipulate these statistics, the module provides a view, `pg_stat_statements`, and the utility functions `pg_stat_statements_reset` and `pg_stat_statements`. These are not available globally but can be enabled for a specific database with `CREATE EXTENSION pg_stat_statements`.

F.46.1. The `pg_stat_statements` View

The statistics gathered by the module are made available via a view named `pg_stat_statements`. This view contains one row for each distinct database ID, user ID and query ID (up to the maximum number of distinct statements that the module can track). The columns of the view are shown in [Table F.106](#).

Table F.106. `pg_stat_statements` Columns

Column Type	Description
<code>userid oid</code> (references <code>pg_authid .oid</code>)	OID of user who executed the statement
<code>dbid oid</code> (references <code>pg_database .oid</code>)	OID of database in which the statement was executed
<code>queryid bigint</code>	Internal hash code, computed from the statement's parse tree
<code>query text</code>	Text of a representative statement
<code>plans bigint</code>	Number of times the statement was planned (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>total_plan_time double precision</code>	Total time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>min_plan_time double precision</code>	Minimum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>max_plan_time double precision</code>	Maximum time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>mean_plan_time double precision</code>	Mean time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>stddev_plan_time double precision</code>	Population standard deviation of time spent planning the statement, in milliseconds (if <code>pg_stat_statements.track_planning</code> is enabled, otherwise zero)
<code>calls bigint</code>	Number of times the statement was executed
<code>total_exec_time double precision</code>	Total time spent executing the statement, in milliseconds
<code>min_exec_time double precision</code>	Minimum time spent executing the statement, in milliseconds
<code>max_exec_time double precision</code>	Maximum time spent executing the statement, in milliseconds

Column Type	Description
mean_exec_time double precision	Mean time spent executing the statement, in milliseconds
stddev_exec_time double precision	Population standard deviation of time spent executing the statement, in milliseconds
rows bigint	Total number of rows retrieved or affected by the statement
shared_blks_hit bigint	Total number of shared block cache hits by the statement
shared_blks_read bigint	Total number of shared blocks read by the statement
shared_blks_dirtied bigint	Total number of shared blocks dirtied by the statement
shared_blks_written bigint	Total number of shared blocks written by the statement
local_blks_hit bigint	Total number of local block cache hits by the statement
local_blks_read bigint	Total number of local blocks read by the statement
local_blks_dirtied bigint	Total number of local blocks dirtied by the statement
local_blks_written bigint	Total number of local blocks written by the statement
temp_blks_read bigint	Total number of temp blocks read by the statement
temp_blks_written bigint	Total number of temp blocks written by the statement
blk_read_time double precision	Total time the statement spent reading blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
blk_write_time double precision	Total time the statement spent writing blocks, in milliseconds (if track_io_timing is enabled, otherwise zero)
wal_records bigint	Total number of WAL records generated by the statement
wal_fpi bigint	Total number of WAL full page images generated by the statement
wal_bytes numeric	Total amount of WAL generated by the statement in bytes

For security reasons, only superusers and members of the `pg_read_all_stats` role are allowed to see the SQL text and `queryid` of queries executed by other users. Other users can see the statistics, however, if the view has been installed in their database.

Plannable queries (that is, `SELECT`, `INSERT`, `UPDATE`, and `DELETE`) are combined into a single `pg_stat_statements` entry whenever they have identical query structures according to an internal hash calculation. Typically, two queries will be considered the same for this purpose if they are semantically equivalent except for the values of literal constants appearing in the query. Utility commands (that is, all other commands) are compared strictly on the basis of their textual query strings, however.

When a constant's value has been ignored for purposes of matching the query to other queries, the constant is replaced by a parameter symbol, such as `$1`, in the `pg_stat_statements` display. The rest of the query text is that of the first query that had the particular `queryid` hash value associated with the `pg_stat_statements` entry.

In some cases, queries with visibly different texts might get merged into a single `pg_stat_statements` entry. Normally this will happen only for semantically equivalent queries, but there is a small chance of hash collisions causing unrelated queries to be merged into one entry. (This cannot happen for queries belonging to different users or databases, however.)

Since the `queryid` hash value is computed on the post-parse-analysis representation of the queries, the opposite is also possible: queries with identical texts might appear as separate entries, if they have different meanings as a result of factors such as different `search_path` settings.

Consumers of `pg_stat_statements` may wish to use `queryid` (perhaps in combination with `dbid` and `userid`) as a more stable and reliable identifier for each entry than its query text. However, it is important to understand that there are only limited guarantees around the stability of the `queryid` hash value. Since the identifier is derived from the post-parse-analysis tree, its value is a function of, among other things, the internal object identifiers appearing in this representation. This has some counterintuitive implications. For example, `pg_stat_statements` will consider two apparently-identical queries to be distinct, if they reference a table that was dropped and recreated between the executions of the two queries. The hashing process is also sensitive to differences in machine architecture and other facets of the platform. Furthermore, it is not safe to assume that `queryid` will be stable across major versions of Postgres Pro.

Two servers participating in replication based on physical WAL replay can be expected to have identical `queryid` values for the same query. However, logical replication schemes do not promise to keep replicas identical in all relevant details, so `queryid` will not be a useful identifier for accumulating costs across a set of logical replicas. If in doubt, direct testing is recommended.

Generally, it can be assumed that `queryid` values are stable between minor version releases of PostgreSQL, providing that instances are running on the same machine architecture and the catalog meta-data details match. Compatibility will only be broken between minor versions as a last resort.

The parameter symbols used to replace constants in representative query texts start from the next number after the highest `$n` parameter in the original query text, or `$1` if there was none. It's worth noting that in some cases there may be hidden parameter symbols that affect this numbering. For example, PL/pgSQL uses hidden parameter symbols to insert values of function local variables into queries, so that a PL/pgSQL statement like `SELECT i + 1 INTO j` would have representative text like `SELECT i + $2`.

The representative query texts are kept in an external disk file, and do not consume shared memory. Therefore, even very lengthy query texts can be stored successfully. However, if many long query texts are accumulated, the external file might grow unmanageably large. As a recovery method if that happens, `pg_stat_statements` may choose to discard the query texts, whereupon all existing entries in the `pg_stat_statements` view will show null `query` fields, though the statistics associated with each `queryid` are preserved. If this happens, consider reducing `pg_stat_statements.max` to prevent recurrences.

`plans` and `calls` aren't always expected to match because planning and execution statistics are updated at their respective end phase, and only for successful operations. For example, if a statement is successfully planned but fails during the execution phase, only its planning statistics will be updated. If planning is skipped because a cached plan is used, only its execution statistics will be updated.

F.46.2. Functions

`pg_stat_statements_reset(userid Oid, dbid Oid, queryid bigint)` returns void

`pg_stat_statements_reset` discards statistics gathered so far by `pg_stat_statements` corresponding to the specified `userid`, `dbid` and `queryid`. If any of the parameters are not specified, the default value 0 (invalid) is used for each of them and the statistics that match with other parameters will be

reset. If no parameter is specified or all the specified parameters are 0 (invalid), it will discard all statistics. By default, this function can only be executed by superusers. Access may be granted to others using `GRANT`.

`pg_stat_statements(showtext boolean)` returns setof record

The `pg_stat_statements` view is defined in terms of a function also named `pg_stat_statements`. It is possible for clients to call the `pg_stat_statements` function directly, and by specifying `showtext := false` have query text be omitted (that is, the `OUT` argument that corresponds to the view's query column will return nulls). This feature is intended to support external tools that might wish to avoid the overhead of repeatedly retrieving query texts of indeterminate length. Such tools can instead cache the first query text observed for each entry themselves, since that is all `pg_stat_statements` itself does, and then retrieve query texts only as needed. Since the server stores query texts in a file, this approach may reduce physical I/O for repeated examination of the `pg_stat_statements` data.

F.46.3. Configuration Parameters

`pg_stat_statements.max (integer)`

`pg_stat_statements.max` is the maximum number of statements tracked by the module (i.e., the maximum number of rows in the `pg_stat_statements` view). If more distinct statements than that are observed, information about the least-executed statements is discarded. The default value is 5000. This parameter can only be set at server start.

`pg_stat_statements.track (enum)`

`pg_stat_statements.track` controls which statements are counted by the module. Specify `top` to track top-level statements (those issued directly by clients), `all` to also track nested statements (such as statements invoked within functions), or `none` to disable statement statistics collection. The default value is `top`. Only superusers can change this setting.

`pg_stat_statements.track_utility (boolean)`

`pg_stat_statements.track_utility` controls whether utility commands are tracked by the module. Utility commands are all those other than `SELECT`, `INSERT`, `UPDATE` and `DELETE`. The default value is `on`. Only superusers can change this setting.

`pg_stat_statements.track_planning (boolean)`

`pg_stat_statements.track_planning` controls whether planning operations and duration are tracked by the module. Enabling this parameter may incur a noticeable performance penalty, especially when statements with identical query structure are executed by many concurrent connections which compete to update a small number of `pg_stat_statements` entries. The default value is `off`. Only superusers can change this setting.

`pg_stat_statements.save (boolean)`

`pg_stat_statements.save` specifies whether to save statement statistics across server shutdowns. If it is `off` then statistics are not saved at shutdown nor reloaded at server start. The default value is `on`. This parameter can only be set in the `postgresql.conf` file or on the server command line.

The module requires additional shared memory proportional to `pg_stat_statements.max`. Note that this memory is consumed whenever the module is loaded, even if `pg_stat_statements.track` is set to `none`.

These parameters must be set in `postgresql.conf`. Typical usage might be:

```
# postgresql.conf
shared_preload_libraries = 'pg_stat_statements'

pg_stat_statements.max = 10000
```

```
pg_stat_statements.track = all
```

F.46.4. Sample Output

```
bench=# SELECT pg_stat_statements_reset();

F.46.5. Authors

Takahiro Itagaki <itagaki.takahiro@oss.ntt.co.jp>. Query normalization added by Peter Geoghegan <peter@2ndquadrant.com>.

F.47. pgstattuple

The `pgstattuple` module provides various functions to obtain tuple-level statistics.

Because these functions return detailed page-level information, access is restricted by default. By default, only the role `pg_stat_scan_tables` has `EXECUTE` privilege. Superusers of course bypass this restriction. After the extension has been installed, users may issue `GRANT` commands to change the privileges on the functions to allow others to execute them. However, it might be preferable to add those users to the `pg_stat_scan_tables` role instead.

F.47.1. Functions

`pgstattuple(regclass)` returns record

`pgstattuple` returns a relation's physical length, percentage of “dead” tuples, and other info. This may help users to determine whether vacuum is necessary or not. The argument is the target relation's name (optionally schema-qualified) or OID. For example:

```
test=> SELECT * FROM pgstattuple('pg_catalog.pg_proc');
-[ RECORD 1 ]-----+-----
table_len          | 458752
tuple_count        | 1470
tuple_len          | 438896
tuple_percent      | 95.67
dead_tuple_count   | 11
dead_tuple_len     | 3157
dead_tuple_percent | 0.69
free_space         | 8932
free_percent       | 1.95
```

The output columns are described in [Table F.107](#).

Table F.107. `pgstattuple` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes
<code>tuple_count</code>	<code>bigint</code>	Number of live tuples
<code>tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes
<code>tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>free_space</code>	<code>bigint</code>	Total free space in bytes
<code>free_percent</code>	<code>float8</code>	Percentage of free space

Note

The `table_len` will always be greater than the sum of the `tuple_len`, `dead_tuple_len` and `free_space`. The difference is accounted for by fixed page overhead, the per-page table of pointers to tuples, and padding to ensure that tuples are correctly aligned.

`pgstattuple` acquires only a read lock on the relation. So the results do not reflect an instantaneous snapshot; concurrent updates will affect them.

`pgstattuple` judges a tuple is “dead” if `HeapTupleSatisfiesDirty` returns false.

`pgstattuple(text)` returns record

This is the same as `pgstattuple(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatindex(regclass)` returns record

`pgstatindex` returns a record showing information about a B-tree index. For example:

```
test=> SELECT * FROM pgstatindex('pg_cast_oid_index');
-[ RECORD 1 ]-----+-----
version          | 2
tree_level       | 0
index_size       | 16384
root_block_no    | 1
internal_pages   | 0
leaf_pages       | 1
empty_pages      | 0
deleted_pages    | 0
avg_leaf_density | 54.27
leaf_fragmentation | 0
```

The output columns are:

Column	Type	Description
version	integer	B-tree version number
tree_level	integer	Tree level of the root page
index_size	bigint	Total index size in bytes
root_block_no	bigint	Location of root page (zero if none)
internal_pages	bigint	Number of “internal” (upper-level) pages
leaf_pages	bigint	Number of leaf pages
empty_pages	bigint	Number of empty pages
deleted_pages	bigint	Number of deleted pages
avg_leaf_density	float8	Average density of leaf pages
leaf_fragmentation	float8	Leaf page fragmentation

The reported `index_size` will normally correspond to one more page than is accounted for by `internal_pages` + `leaf_pages` + `empty_pages` + `deleted_pages`, because it also includes the index's metapage.

As with `pgstattuple`, the results are accumulated page-by-page, and should not be expected to represent an instantaneous snapshot of the whole index.

`pgstatindex(text)` returns record

This is the same as `pgstatindex(regclass)`, except that the target index is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstatginindex(regclass)` returns record

`pgstatginindex` returns a record showing information about a GIN index. For example:

```
test=> SELECT * FROM pgstatginindex('test_gin_index');
-[ RECORD 1 ]--+-
```

```
version          | 1
pending_pages    | 0
pending_tuples   | 0
```

The output columns are:

Column	Type	Description
version	integer	GIN version number
pending_pages	integer	Number of pages in the pending list
pending_tuples	bigint	Number of tuples in the pending list

`pgstathashindex(regclass)` returns record

`pgstathashindex` returns a record showing information about a HASH index. For example:

```
test=> select * from pgstathashindex('con_hash_index');
-[ RECORD 1 ]--+-+-----
version          | 4
bucket_pages     | 33081
overflow_pages   | 0
bitmap_pages     | 1
unused_pages     | 32455
live_items       | 10204006
dead_items       | 0
free_percent     | 61.8005949100872
```

The output columns are:

Column	Type	Description
version	integer	HASH version number
bucket_pages	bigint	Number of bucket pages
overflow_pages	bigint	Number of overflow pages
bitmap_pages	bigint	Number of bitmap pages
unused_pages	bigint	Number of unused pages
live_items	bigint	Number of live tuples
dead_tuples	bigint	Number of dead tuples
free_percent	float	Percentage of free space

`pg_relpages(regclass)` returns bigint

`pg_relpages` returns the number of pages in the relation.

`pg_relpages(text)` returns bigint

This is the same as `pg_relpages(regclass)`, except that the target relation is specified as TEXT. This function is kept because of backward-compatibility so far, and will be deprecated in some future release.

`pgstattuple_approx(regclass)` returns record

`pgstattuple_approx` is a faster alternative to `pgstattuple` that returns approximate results. The argument is the target relation's name or OID. For example:

```
test=> SELECT * FROM pgstattuple_approx('pg_catalog.pg_proc'::regclass);
-[ RECORD 1 ]-----+-----
table_len          | 573440
```

```

scanned_percent      | 2
approx_tuple_count   | 2740
approx_tuple_len      | 561210
approx_tuple_percent  | 97.87
dead_tuple_count      | 0
dead_tuple_len        | 0
dead_tuple_percent    | 0
approx_free_space     | 11996
approx_free_percent   | 2.09

```

The output columns are described in [Table F.108](#).

Whereas `pgstattuple` always performs a full-table scan and returns an exact count of live and dead tuples (and their sizes) and free space, `pgstattuple_approx` tries to avoid the full-table scan and returns exact dead tuple statistics along with an approximation of the number and size of live tuples and free space.

It does this by skipping pages that have only visible tuples according to the visibility map (if a page has the corresponding VM bit set, then it is assumed to contain no dead tuples). For such pages, it derives the free space value from the free space map, and assumes that the rest of the space on the page is taken up by live tuples.

For pages that cannot be skipped, it scans each tuple, recording its presence and size in the appropriate counters, and adding up the free space on the page. At the end, it estimates the total number of live tuples based on the number of pages and tuples scanned (in the same way that `VACUUM` estimates `pg_class.relpages`).

Table F.108. `pgstattuple_approx` Output Columns

Column	Type	Description
<code>table_len</code>	<code>bigint</code>	Physical relation length in bytes (exact)
<code>scanned_percent</code>	<code>float8</code>	Percentage of table scanned
<code>approx_tuple_count</code>	<code>bigint</code>	Number of live tuples (estimated)
<code>approx_tuple_len</code>	<code>bigint</code>	Total length of live tuples in bytes (estimated)
<code>approx_tuple_percent</code>	<code>float8</code>	Percentage of live tuples
<code>dead_tuple_count</code>	<code>bigint</code>	Number of dead tuples (exact)
<code>dead_tuple_len</code>	<code>bigint</code>	Total length of dead tuples in bytes (exact)
<code>dead_tuple_percent</code>	<code>float8</code>	Percentage of dead tuples
<code>approx_free_space</code>	<code>bigint</code>	Total free space in bytes (estimated)
<code>approx_free_percent</code>	<code>float8</code>	Percentage of free space

In the above output, the free space figures may not match the `pgstattuple` output exactly, because the free space map gives us an exact figure, but is not guaranteed to be accurate to the byte.

F.47.2. Authors

Tatsuo Ishii, Satoshi Nagayasu and Abhijit Menon-Sen

F.48. `pg_transfer`

The `pg_transfer` extension enables quick transfer of tables between Postgres Pro Enterprise instances.

It may sometimes be required to load large volumes of data into a database, for example, when consolidating data from regional servers into a central one. If your data needs to be uploaded to a server under heavy load, you can use a temporary database on another server to accumulate the data and then transfer it all at once when the main server load is minimal.

If you use `pg_dump` and `pg_restore` applications to transfer data, the load on the receiving server is usually higher than that on the sending server. Since the data is loaded using `INSERT` or `COPY` commands, it creates a significant impact on the disk subsystem. Besides, you will have to re-build indexes in the target database once all the data is loaded, which will also contribute to the server load.

To achieve a much higher load speed for read-only data, you can use the `pg_transfer` extension while doing dump/restore, which allows to copy data files directly, without using `COPY/INSERT` commands. `pg_transfer` also provides auxiliary functions for `pg_dump` and `pg_restore` to transfer tables together with pre-built indexes and collected statistics, so you can avoid extra load on the target server incurred by statistics re-collection.

Note

Postgres Pro Enterprise configuration and the architectures of source and target servers must provide binary-compatible file formats. When restoring data, `pg_transfer` checks that source and target servers have the same alignment, page and segment sizes, etc.

F.48.1. Installation

`pg_transfer` is included into Postgres Pro Enterprise. To enable `pg_transfer`, create its extension in your database using the following SQL command:

```
CREATE EXTENSION pg_transfer;
```

You must create `pg_transfer` extension in both source and target databases.

F.48.2. Usage

To transfer data using the `pg_transfer` module, do the following:

1. Prepare source and target systems for data transfer

Before the actual data transfer, you first need to transfer data schema to the target server:

1. In the source database, mark the table to be transferred as read-only:

```
ALTER TABLE table_name SET CONSTANT;
```

2. Run the `VACUUM (ANALYZE)` command to remove dead tuples and refresh statistics:

```
VACUUM (ANALYZE) table_name;
```

3. Take a logical dump of the data schema on the source server and restore it on the target server:

```
pg_dump -Fc -t table_name --schema-only -f transfer_dir/archive.out old_database  
pg_restore -d new_database --schema-only transfer_dir/archive.out
```

2. Prepare TOAST identifiers for the transfer

This step is only required if the tables to be transferred have toasted values.

1. Determine TOAST identifiers (`reltoastid`) in the new database:

```
psql new_database -c "SELECT reltoastrelid FROM pg_class WHERE  
relname='table_name';"
```

2. Using the received `reltoastid` identifiers, prepare the table for the transfer and force data flush to disk:

```
psql -d old_database -c "SELECT
pg_transfer_freeze('table_name'::regclass::oid, reltoastrelid::oid);"
```

3. Transfer the data to the target system

1. Copy the data into a separate directory using `pg_dump` utility:

```
pg_dump -Fc -t table_name --transfer-dir transfer_dir/ -f transfer_dir/
archive.out old_database
```

2. Restore the data in the target database:

```
pg_restore -d new_database --data-only --transfer-dir transfer_dir/ --copy-mode-
transfer transfer_dir/archive.out
```

When source and target databases are located in the same file system, the `--copy-mode-transfer` option must be specified at least once (for either `pg_dump` or `pg_restore` command) to get an independent copy of data. When restoring data on the primary server, `--generate-wal` option must be specified for `pg_restore` for changes to be replicated to a standby server.

F.48.3. Compatibility

The `pg_transfer` extension is only supported on Linux systems.

F.48.4. Authors

Postgres Professional, Moscow, Russia

F.49. pg_trgm

The `pg_trgm` module provides functions and operators for determining the similarity of alphanumeric text based on trigram matching, as well as index operator classes that support fast searching for similar strings.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.49.1. Trigram (or Trigraph) Concepts

A trigram is a group of three consecutive characters taken from a string. We can measure the similarity of two strings by counting the number of trigrams they share. This simple idea turns out to be very effective for measuring the similarity of words in many natural languages.

Note

`pg_trgm` ignores non-word characters (non-alphanumerics) when extracting trigrams from a string. Each word is considered to have two spaces prefixed and one space suffixed when determining the set of trigrams contained in the string. For example, the set of trigrams in the string “cat” is “ c”, “ ca”, “cat”, and “at ”. The set of trigrams in the string “foo|bar” is “ f”, “ fo”, “foo”, “oo ”, “ b”, “ ba”, “bar”, and “ar ”.

F.49.2. Functions and Operators

The functions provided by the `pg_trgm` module are shown in [Table F.109](#), the operators in [Table F.110](#).

Table F.109. `pg_trgm` Functions

Function	Description
<code>similarity (text, text) → real</code>	

Function	Description
	Returns a number that indicates how similar the two arguments are. The range of the result is zero (indicating that the two strings are completely dissimilar) to one (indicating that the two strings are identical).
<code>show_trgm (text) → text[]</code>	Returns an array of all the trigrams in the given string. (In practice this is seldom useful except for debugging.)
<code>word_similarity (text, text) → real</code>	Returns a number that indicates the greatest similarity between the set of trigrams in the first string and any continuous extent of an ordered set of trigrams in the second string. For details, see the explanation below.
<code>strict_word_similarity (text, text) → real</code>	Same as <code>word_similarity</code> , but forces extent boundaries to match word boundaries. Since we don't have cross-word trigrams, this function actually returns greatest similarity between first string and any continuous extent of words of the second string.
<code>show_limit () → real</code>	Returns the current similarity threshold used by the <code>%</code> operator. This sets the minimum similarity between two words for them to be considered similar enough to be misspellings of each other, for example. (<i>Deprecated</i> ; instead use <code>SHOW pg_trgm.similarity_threshold .</code>)
<code>set_limit (real) → real</code>	Sets the current similarity threshold that is used by the <code>%</code> operator. The threshold must be between 0 and 1 (default is 0.3). Returns the same value passed in. (<i>Deprecated</i> ; instead use <code>SET pg_trgm.similarity_threshold .</code>)

Consider the following example:

```
# SELECT word_similarity('word', 'two words');
word_similarity
-----
0.8
(1 row)
```

In the first string, the set of trigrams is {" w", " wo", "wor", "ord", "rd "}. In the second string, the ordered set of trigrams is {" t", " tw", "two", "wo ", " w", " wo", "wor", "ord", "rds", "ds "}. The most similar extent of an ordered set of trigrams in the second string is {" w", " wo", "wor", "ord"}, and the similarity is 0.8.

This function returns a value that can be approximately understood as the greatest similarity between the first string and any substring of the second string. However, this function does not add padding to the boundaries of the extent. Thus, the number of additional characters present in the second string is not considered, except for the mismatched word boundaries.

At the same time, `strict_word_similarity` selects an extent of words in the second string. In the example above, `strict_word_similarity` would select the extent of a single word 'words', whose set of trigrams is {" w", " wo", "wor", "ord", "rds", "ds "}.

```
# SELECT strict_word_similarity('word', 'two words'), similarity('word', 'words');
strict_word_similarity | similarity
-----+-----
0.571429 | 0.571429
(1 row)
```

Thus, the `strict_word_similarity` function is useful for finding the similarity to whole words, while `word_similarity` is more suitable for finding the similarity for parts of words.

Table F.110. pg_trgm Operators

Operator	Description
<code>text % text → boolean</code>	Returns <code>true</code> if its arguments have a similarity that is greater than the current similarity threshold set by <code>pg_trgm.similarity_threshold</code> .
<code>text <% text → boolean</code>	Returns <code>true</code> if the similarity between the trigram set in the first argument and a continuous extent of an ordered trigram set in the second argument is greater than the current word similarity threshold set by <code>pg_trgm.word_similarity_threshold</code> parameter.
<code>text %> text → boolean</code>	Commutator of the <code><%</code> operator.
<code>text <<% text → boolean</code>	Returns <code>true</code> if its second argument has a continuous extent of an ordered trigram set that matches word boundaries, and its similarity to the trigram set of the first argument is greater than the current strict word similarity threshold set by the <code>pg_trgm.strict_word_similarity_threshold</code> parameter.
<code>text %>> text → boolean</code>	Commutator of the <code><<%</code> operator.
<code>text <-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>similarity()</code> value.
<code>text <<-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>word_similarity()</code> value.
<code>text <->> text → real</code>	Commutator of the <code><<-></code> operator.
<code>text <<<-> text → real</code>	Returns the “distance” between the arguments, that is one minus the <code>strict_word_similarity()</code> value.
<code>text <->>> text → real</code>	Commutator of the <code><<<-></code> operator.

F.49.3. GUC Parameters

`pg_trgm.similarity_threshold (real)`

Sets the current similarity threshold that is used by the `%` operator. The threshold must be between 0 and 1 (default is 0.3).

`pg_trgm.word_similarity_threshold (real)`

Sets the current word similarity threshold that is used by the `<%` and `%>` operators. The threshold must be between 0 and 1 (default is 0.6).

`pg_trgm.strict_word_similarity_threshold (real)`

Sets the current strict word similarity threshold that is used by the `<<%` and `%>>` operators. The threshold must be between 0 and 1 (default is 0.5).

F.49.4. Index Support

The `pg_trgm` module provides GiST and GIN index operator classes that allow you to create an index over a text column for the purpose of very fast similarity searches. These index types support the above-

described similarity operators, and additionally support trigram-based index searches for `LIKE`, `ILIKE`, `~` and `~*` queries. (These indexes do not support equality nor simple comparison operators, so you may need a regular B-tree index too.)

Example:

```
CREATE TABLE test_trgm (t text);
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops);
```

or

```
CREATE INDEX trgm_idx ON test_trgm USING GIN (t gin_trgm_ops);
```

`gist_trgm_ops` GiST opclass approximates a set of trigrams as a bitmap signature. Its optional integer parameter `siglen` determines the signature length in bytes. The default length is 12 bytes. Valid values of signature length are between 1 and 2024 bytes. Longer signatures lead to a more precise search (scanning a smaller fraction of the index and fewer heap pages), at the cost of a larger index.

Example of creating such an index with a signature length of 32 bytes:

```
CREATE INDEX trgm_idx ON test_trgm USING GIST (t gist_trgm_ops(siglen=32));
```

At this point, you will have an index on the `t` column that you can use for similarity searching. A typical query is

```
SELECT t, similarity(t, 'word') AS sml
FROM test_trgm
WHERE t % 'word'
ORDER BY sml DESC, t;
```

This will return all values in the text column that are sufficiently similar to *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

A variant of the above query is

```
SELECT t, t <-> 'word' AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes. It will usually beat the first formulation when only a small number of the closest matches is wanted.

Also you can use an index on the `t` column for word similarity or strict word similarity. Typical queries are:

```
SELECT t, word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <% t
ORDER BY sml DESC, t;
```

and

```
SELECT t, strict_word_similarity('word', t) AS sml
FROM test_trgm
WHERE 'word' <<% t
ORDER BY sml DESC, t;
```

This will return all values in the text column for which there is a continuous extent in the corresponding ordered trigram set that is sufficiently similar to the trigram set of *word*, sorted from best match to worst. The index will be used to make this a fast operation even over very large data sets.

Possible variants of the above queries are:

```
SELECT t, 'word' <<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

and

```
SELECT t, 'word' <<<-> t AS dist
FROM test_trgm
ORDER BY dist LIMIT 10;
```

This can be implemented quite efficiently by GiST indexes, but not by GIN indexes.

Beginning in PostgreSQL 9.1, these index types also support index searches for `LIKE` and `ILIKE`, for example

```
SELECT * FROM test_trgm WHERE t LIKE '%foo%bar';
```

The index search works by extracting trigrams from the search string and then looking these up in the index. The more trigrams in the search string, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

Beginning in PostgreSQL 9.3, these index types also support index searches for regular-expression matches (`~` and `~*` operators), for example

```
SELECT * FROM test_trgm WHERE t ~ '(foo|bar)';
```

The index search works by extracting trigrams from the regular expression and then looking these up in the index. The more trigrams that can be extracted from the regular expression, the more effective the index search is. Unlike B-tree based searches, the search string need not be left-anchored.

For both `LIKE` and regular-expression searches, keep in mind that a pattern with no extractable trigrams will degenerate to a full-index scan.

The choice between GiST and GIN indexing depends on the relative performance characteristics of GiST and GIN, which are discussed elsewhere.

F.49.5. Text Search Integration

Trigram matching is a very useful tool when used in conjunction with a full text index. In particular it can help to recognize misspelled input words that will not be matched directly by the full text search mechanism.

The first step is to generate an auxiliary table containing all the unique words in the documents:

```
CREATE TABLE words AS SELECT word FROM
    ts_stat('SELECT to_tsvector(''simple'', bodytext) FROM documents');
```

where `documents` is a table that has a text field `bodytext` that we wish to search. The reason for using the `simple` configuration with the `to_tsvector` function, instead of using a language-specific configuration, is that we want a list of the original (unstemmed) words.

Next, create a trigram index on the word column:

```
CREATE INDEX words_idx ON words USING GIN (word gin_trgm_ops);
```

Now, a `SELECT` query similar to the previous example can be used to suggest spellings for misspelled words in user search terms. A useful extra test is to require that the selected words are also of similar length to the misspelled word.

Note

Since the `words` table has been generated as a separate, static table, it will need to be periodically regenerated so that it remains reasonably up-to-date with the document collection. Keeping it exactly current is usually unnecessary.

F.50. pg_tsparser

`pg_tsparser` is a Postgres Pro extension for text search. This extension modifies the default text parsing strategy for words that include:

- underscores
- numbers and letters separated by the hyphen character

In addition to separate word parts returned by default, `pg_tsparser` also returns the whole word.

F.50.1. Installation and Setup

`pg_tsparser` is included into the Postgres Pro distribution. To enable `pg_tsparser`, once Postgres Pro is installed, create the `pg_tsparser` extension for each database you are planning to use:

```
CREATE EXTENSION pg_tsparser;
```

Once `pg_tsparser` is enabled, you can create your own text search configuration. In addition to `pg_tsparser`, you can use any available dictionary.

For example, you can create `english_ts` configuration for the English language, as follows:

```
CREATE TEXT SEARCH CONFIGURATION english_ts (  
    PARSER = tsparser  
);
```

```
COMMENT ON TEXT SEARCH CONFIGURATION english_ts IS 'text search configuration for  
english language';
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR email, file, float, host, hword_numpart, int,  
    numhword, numword, sfloat, uint, url, url_path, version  
    WITH simple;
```

```
ALTER TEXT SEARCH CONFIGURATION english_ts  
    ADD MAPPING FOR asciiword, asciihword, hword_asciipart,  
    word, hword, hword_part  
    WITH english_stem;
```

F.50.2. Examples

The following examples illustrate the difference in search results returned by `pg_tsparser` and the default parser:

```
SELECT to_tsvector('english', 'pg_trgm') as def_parser,  
       to_tsvector('english_ts', 'pg_trgm') as new_parser;  
def_parser      |      new_parser  
-----+-----
```

```
'pg':1 'trgm':2 | 'pg':2 'pg_trgm':1 'trgm':3
(1 row)
```

```
SELECT to_tsvector('english', '123-abc') as def_parser,
       to_tsvector('english_ts', '123-abc') as new_parser;
 def_parser | new_parser
-----+-----
 '123':1 'abc':2 | '123':2 '123-abc':1 'abc':3
(1 row)
```

```
SELECT to_tsvector('english', 'rel-3.2-A') as def_parser,
       to_tsvector('english_ts', 'rel-3.2-A') as new_parser;
 def_parser | new_parser
-----+-----
 '-3.2':2 'rel':1 | '3.2':3 'rel':2 'rel-3.2-a':1
(1 row)
```

See Also[CREATE TEXT SEARCH CONFIGURATION](#)[ALTER TEXT SEARCH CONFIGURATION](#)**F.50.3. Authors**

Postgres Professional, Moscow, Russia

F.51. pg_variables

The `pg_variables` module provides functions for working with variables of various types. The created variables are only available in the current user session.

Note

This extension cannot be used while built-in connection pooling is enabled.

F.51.1. Installation

The `pg_variables` extension is included into Postgres Pro. Once you have Postgres Pro installed, you must execute the [CREATE EXTENSION](#) command to enable `pg_variables`, as follows:

```
CREATE EXTENSION pg_variables;
```

F.51.2. Usage

The `pg_variables` module provides several functions for creating, reading, and managing variables of scalar, record, and array types. See the following sections for function descriptions and syntax:

- [Section F.51.3.1](#) describes functions for scalar variables.
- [Section F.51.3.2](#) describes functions for collections of record variables.
- [Section F.51.3.3](#) describes functions for array variables.
- [Section F.51.3.4](#) describes functions for general collection variables.
- [Section F.51.3.5](#) describes functions for using iterators to traverse collection variables.
- [Section F.51.3.6](#) lists functions you can use to manage all variables in your current session.

For detailed usage examples, see [Section F.51.5](#).

F.51.2.1. Using Transactional Variables

By default, the created variables are non-transactional. Once successfully set, a variable exists for the whole session, regardless of rollbacks, if any. For example:

```

SELECT pgv_set('vars', 'int1', 101);
BEGIN;
SELECT pgv_set('vars', 'int2', 102);
ROLLBACK;

SELECT * FROM pgv_list() order by package, name;
package | name | is_transactional
-----+-----+-----
vars    | int1 | f
vars    | int2 | f

```

If you would like to use variables that support transactions and savepoints, pass the optional `is_transactional` flag as the last parameter when creating this variable:

```

BEGIN;
SELECT pgv_set('vars', 'trans_int', 101, true);
SAVEPOINT sp1;
SELECT pgv_set('vars', 'trans_int', 102, true);
ROLLBACK TO sp1;
COMMIT;
SELECT pgv_get('vars', 'trans_int', NULL::int);
pgv_get
-----
      101

```

You must use the `is_transactional` flag every time you change the value of a transactional variable using `pgv_set()` or `pgv_insert()` functions. Otherwise, an error occurs. Other functions do not require this flag.

```

SELECT pgv_insert('pack', 'var_record', row(123::int, 'text'::text), true);

SELECT pgv_insert('pack', 'var_record', row(456::int, 'another text'::text));
ERROR:  variable "var_record" already created as TRANSACTIONAL

SELECT pgv_delete('pack', 'var_record', 123::int);

```

If the `pgv_free()` or `pgv_remove()` function calls are rolled back, the affected transactional variables will be restored, unlike non-transactional variables, which are removed permanently. For example:

```

SELECT pgv_set('pack', 'var_reg', 123);
SELECT pgv_set('pack', 'var_trans', 456, true);
BEGIN;
SELECT pgv_free();
ROLLBACK;
SELECT * FROM pgv_list();
package | name | is_transactional
-----+-----+-----
pack    | var_trans | t

```

F.51.3. Functions

F.51.3.1. Scalar Variables

The following functions support scalar variables:

Function	Returns
<code>pgv_set(package text, name text, value anynonarray, is_transactional bool default false)</code>	void

Function	Returns
<code>pgv_get(package text, name text, var_type anynonarray, strict bool default true)</code>	<code>anynonarray</code>

To use the `pgv_get()` function, you must first create a package and a variable using the `pgv_set()` function. If the specified package or variable does not exist, an error occurs:

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized package "vars"
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
ERROR: unrecognized variable "int1"
```

`pgv_get()` function checks the variable type. If the specified type does not match the type of the variable, an error is raised:

```
SELECT pgv_get('vars', 'int1', NULL::text);
ERROR: variable "int1" requires "integer" value
```

F.51.3.2. Collections of Records

The following functions support collections of record variables:

Function	Returns	Description
<code>pgv_insert(package text, name text, r record, is_transactional bool default false)</code>	<code>void</code>	Inserts a record into a collection variable for the specified package. If the package or variable does not exist, it is created automatically. The first column of <code>r</code> is the primary key. If a record with the same primary key already exists or this collection variable has a different structure, an error is raised.
<code>pgv_update(package text, name text, r record)</code>	<code>boolean</code>	Updates a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found. If this collection variable has a different structure, an error is raised.
<code>pgv_delete(package text, name text, value anynonarray)</code>	<code>boolean</code>	Deletes a record with the corresponding primary key (the first column of <code>r</code> is the primary key). Returns <code>true</code> if the record was found and <code>false</code> otherwise.
<code>pgv_select(package text, name text)</code>	<code>set of records</code>	Returns the collection variable records.
<code>pgv_select(package text, name text, value anynonarray)</code>	<code>record</code>	Returns the record with the corresponding primary key (the first column of <code>r</code> is a primary key).
<code>pgv_select(package text, name text, value anyarray)</code>	<code>set of records</code>	Returns the collection variable records with the corresponding primary keys (the first column of <code>r</code> is a primary key).

To use `pgv_update()`, `pgv_delete()` and `pgv_select()` functions, you must first create a package and a variable using the `pgv_insert()` function. The variable type and the record type must be the same; otherwise, an error occurs.

F.51.3.3. Arrays

The following functions support array variables:

Function	Returns
<code>pgv_set(package text, name text, value anyarray, is_transactional bool default false)</code>	void
<code>pgv_get(package text, name text, var_type anyarray, strict bool default true)</code>	anyarray

Usage instructions for these functions are the same as those provided in [Section F.51.3.1](#) for scalar variables.

F.51.3.4. General Collections

The following functions support general collection variables:

Function	Returns	Description
<code>pgv_set_elem(package text, name text, key int, value anyelement, is_transactional bool default false)</code> <code>pgv_set_elem(package text, name text, key text, value anyelement, is_transactional bool default false)</code>	void	Sets a value for the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If the package or variable does not exist, it is created automatically. Inside one collection, only keys of the same type are allowed. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If an element with the specified key already exists, its value is set to the new one. <code>is_transactional</code> shows whether the new variable is transactional and equals <code>false</code> by default. So if the variable already exists, it must be transactional/non-transactional as indicated by <code>is_transactional</code> , otherwise an error is raised. If the collection already exists and its value type does not match the type of the new value, an error is also raised.
<code>pgv_get_elem(package text, name text, key int, val_type anyelement)</code> <code>pgv_get_elem(package text, name text, key text, val_type anyelement)</code>	anyelement	Returns the value of the element with the key <code>key</code> of the collection variable <code>name</code> in the package <code>package</code> . If there is no element with the specified key in this collection, returns NULL. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is

Function	Returns	Description
		not a collection, an error is also raised. The <code>val_type</code> argument is required to properly determine the return type.
<code>pgv_exists_elem(package text, name text, key int)</code> <code>pgv_exists_elem(package text, name text, key text)</code>	bool	Returns <code>true</code> if an element with the key <code>key</code> exists in the collection variable <code>name</code> in the package <code>package</code> and <code>false</code> otherwise. If the package or variable does not exist, also returns <code>false</code> . The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the specified variable is not a collection, an error is raised.
<code>pgv_remove_elem(package text, name text, key int)</code> <code>pgv_remove_elem(package text, name text, key text)</code>	void	Removes the element with the key <code>key</code> from the collection variable <code>name</code> in the package <code>package</code> . If there is no element with the specified key in this collection, does nothing. The <code>key</code> argument can have either <code>int</code> or <code>text</code> type. If the package or variable does not exist, an error is raised. If the specified variable is not a collection, an error is also raised.

Important

Collections initialized with `pgv_set_elem()` and with `pgv_insert()` are not considered compatible.

F.51.3.5. Iterators

The following functions are provided to use iterators to traverse collection variables. These functions work with collections initialized with both `pgv_set_elem()` and `pgv_insert()`.

Function	Returns	Description
<code>pgv_first(package text, name text, key_type anyelement)</code>	anyelement	Returns the first key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_last(package text, name text, key_type anyelement)</code>	anyelement	Returns the last key from the collection variable. Collections are sorted by the key in ascending order. <code>key_type</code> is required to determine the return value. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.

Function	Returns	Description
<code>pgv_next(package text, name text, key anyelement)</code>	<code>anyelement</code>	Returns the next key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns <code>NULL</code> if used for the last key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_prior(package text, name text, key anyelement)</code>	<code>anyelement</code>	Returns the previous key from the collection variable. The <code>key</code> passed may not exist in the collection. Returns <code>NULL</code> if used for the first key in the collection. Collections are sorted by the key in ascending order. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.
<code>pgv_count(package text, name text)</code>	<code>integer</code>	Returns the number of elements in the collection. If the <code>name</code> passed is the name of a non-collection variable, an error is raised.

F.51.3.6. Miscellaneous Functions

Function	Returns	Description
<code>pgv_exists(package text, name text)</code>	<code>bool</code>	Returns <code>true</code> if the specified package and variable exist and <code>false</code> otherwise.
<code>pgv_exists(package text)</code>	<code>bool</code>	Returns <code>true</code> if the specified package exists and <code>false</code> otherwise.
<code>pgv_remove(package text, name text)</code>	<code>void</code>	Removes the variable with the specified name. The specified package and variable must exist; otherwise, an error is raised.
<code>pgv_remove(package text)</code>	<code>void</code>	Removes the specified package and all the corresponding variables. The specified package must exist; otherwise, an error is raised.
<code>pgv_free()</code>	<code>void</code>	Removes all packages and variables.
<code>pgv_list()</code>	<code>table(package text, name text, is_transactional bool)</code>	Displays all the available variables and the corresponding packages, as well as whether each variable is transactional.
<code>pgv_stats()</code>	<code>table(package text, allocated_memory bigint)</code>	Returns the list of assigned packages and the amount of memory used by variables, in bytes. If you

Function	Returns	Description
		are using transactional variables, this list also includes all deleted packages that still may be restored by a <code>ROLLBACK</code> . This function only supports Postgres Pro 9.6 or higher.

F.51.3.7. Deprecated Functions

F.51.3.7.1. Integer Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_int(package text, name text, value int, is_transactional bool default false)</code>	void
<code>pgv_get_int(package text, name text, strict bool default true)</code>	int

F.51.3.7.2. Text Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_text(package text, name text, value text, is_transactional bool default false)</code>	void
<code>pgv_get_text(package text, name text, strict bool default true)</code>	text

F.51.3.7.3. Numeric Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_numeric(package text, name text, value numeric, is_transactional bool default false)</code>	void
<code>pgv_get_numeric(package text, name text, strict bool default true)</code>	numeric

F.51.3.7.4. Timestamp Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestamp(package text, name text, value timestamp, is_transactional bool default false)</code>	void
<code>pgv_get_timestamp(package text, name text, strict bool default true)</code>	timestamp

F.51.3.7.5. Timestamp with timezone Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_timestampz(package text, name text, value timestampz, is_transactional bool default false)</code>	void
<code>pgv_get_timestampz(package text, name text, strict bool default true)</code>	timestampz

F.51.3.7.6. Date Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_date(package text, name text, value date, is_transactional bool default false)</code>	void
<code>pgv_get_date(package text, name text, strict bool default true)</code>	date

F.51.3.7.7. Jsonb Variables

The following functions are deprecated. Use generic functions for [scalar variables](#) instead.

Function	Returns
<code>pgv_set_jsonb(package text, name text, value jsonb, is_transactional bool default false)</code>	void
<code>pgv_get_jsonb(package text, name text, strict bool default true)</code>	jsonb

F.51.4. Important Notes

F.51.4.1. Collations in Collections

Collections are stored in ascending order. In the case of `text` keys, you need a collation to determine the order of elements. If no collation is specified when inserting the first element of a collection, the default collation is used. Otherwise, the specified collation is used.

F.51.4.2. Cursors for Set-Returning Functions

All set-returning functions except `pgv_select(package, variable)` fix their return results at first `FETCH` from the cursor and are not affected by further data manipulation.

The results of `pgv_select(package, variable)` are received dynamically and are affected by transactions/changes in the collection. For `pgv_select()` called for a transactional collection, cursors look at the snapshot of the collection when the first `FETCH` was executed, but consider changes that were made in that transaction and in committed subtransactions.

F.51.5. Examples

Define scalar variables using the `pgv_set()` function, and then return their values using the `pgv_get()` function:

```
SELECT pgv_set('vars', 'int1', 101);
SELECT pgv_set('vars', 'int2', 102);
SELECT pgv_set('vars', 'text1', 'text variable'::text);
```

```
SELECT pgv_get('vars', 'int1', NULL::int);
pgv_get
-----
      101

SELECT pgv_get('vars', 'int2', NULL::int);
pgv_get
-----
      102

SELECT pgv_get('vars', 'text1', NULL::text);
pgv_get
-----
text variable
```

Let's assume we have the `tab` table and examine several examples of using record variables:

```
CREATE TABLE tab (id int, t varchar);
INSERT INTO tab VALUES (0, 'str00'), (1, 'str11');
```

You can use the following functions to work with record variables:

```
SELECT pgv_insert('vars', 'r1', tab) FROM tab;

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(1,str11)
(0,str00)

SELECT pgv_select('vars', 'r1', 1);
pgv_select
-----
(1,str11)

SELECT pgv_select('vars', 'r1', 0);
pgv_select
-----
(0,str00)

SELECT pgv_select('vars', 'r1', ARRAY[1, 0]);
pgv_select
-----
(1,str11)
(0,str00)

SELECT pgv_delete('vars', 'r1', 1);

SELECT pgv_select('vars', 'r1');
pgv_select
-----
(0,str00)
```

Consider the behavior of a transactional variable `var_text` when changed before and after savepoints:

```
SELECT pgv_set('pack', 'var_text', 'before transaction block'::text, true);
BEGIN;
SELECT pgv_set('pack', 'var_text', 'before savepoint'::text, true);
SAVEPOINT sp1;
SELECT pgv_set('pack', 'var_text', 'savepoint sp1'::text, true);
```

```
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_text', 'savepoint sp2'::text, true);
RELEASE sp2;
SELECT pgv_get('pack', 'var_text', NULL::text);
      pgv_get
-----
savepoint sp2

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_text', NULL::text);
      pgv_get
-----
before savepoint

ROLLBACK;
SELECT pgv_get('pack', 'var_text', NULL::text);
      pgv_get
-----
before transaction block
```

If you create a variable after `BEGIN` or `SAVEPOINT` statements and then rollback to the previous state, the transactional variable is removed:

```
BEGIN;
SAVEPOINT sp1;
SAVEPOINT sp2;
SELECT pgv_set('pack', 'var_int', 122, true);
RELEASE SAVEPOINT sp2;
SELECT pgv_get('pack', 'var_int', NULL::int);
      pgv_get
-----
      122

ROLLBACK TO sp1;
SELECT pgv_get('pack', 'var_int', NULL::int);
ERROR:  unrecognized variable "var_int"
COMMIT;
```

List the available packages and variables:

```
SELECT * FROM pgv_list() ORDER BY package, name;
package | name | is_transactional
-----+-----+-----
pack    | var_text | t
vars    | int1    | f
vars    | int2    | f
vars    | r1      | f
vars    | text1   | f
```

Get the amount of memory used by variables, in bytes:

```
SELECT * FROM pgv_stats() ORDER BY package;
package | allocated_memory
-----+-----
pack    | 16384
vars    | 32768
```

Delete the specified variables or packages:

```
SELECT pgv_remove('vars', 'int1');
SELECT pgv_remove('vars');
```

Delete all packages and variables:

```
SELECT pgv_free();
```

These examples show usage of collection variables and iterator functions:

```
sql
SELECT pgv_set_elem('pack', 'var', 1, 1);
SELECT pgv_set_elem('pack', 'var', 5, 5);
SELECT pgv_set_elem('pack', 'var', 10, 10);

SELECT pgv_first('pack', 'var', NULL::int);
pgv_first
-----
      1

SELECT pgv_last('pack', 'var', NULL::int);
pgv_last
-----
     10

SELECT pgv_next('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_next
-----
      5

SELECT pgv_prior('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----
      5

SELECT pgv_prior('pack', 'var', pgv_first('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_prior
-----

SELECT pgv_next('pack', 'var', 3);
pgv_next
-----
      5

SELECT pgv_prior('pack', 'var', 3);
pgv_prior
-----
      1

SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
     10

SELECT pgv_remove_elem('pack', 'var', pgv_last('pack', 'var', NULL::int));
pgv_remove_elem
-----
```

```
SELECT pgv_get_elem('pack', 'var', pgv_last('pack', 'var', NULL::int), NULL::int);
pgv_get_elem
-----
          5
(1 row)
```

These examples show how the collation affects the order of elements in a collection. They also show how to iterate over a whole collection with PL/pgSQL loops:

```
sql
SELECT pgv_set_elem('pack', 'var1', 'a' COLLATE "ru_RU", 'a'::text);
SELECT pgv_set_elem('pack', 'var1', 'д' COLLATE "ru_RU", 'д'::text);
SELECT pgv_set_elem('pack', 'var1', 'e' COLLATE "ru_RU", 'e'::text);
SELECT pgv_set_elem('pack', 'var1', 'ë' COLLATE "ru_RU", 'ë'::text);
SELECT pgv_set_elem('pack', 'var1', 'ж' COLLATE "ru_RU", 'ж'::text);
SELECT pgv_set_elem('pack', 'var1', 'я' COLLATE "ru_RU", 'я'::text);
DO
$$
DECLARE
    iter text;
BEGIN
    iter := pgv_first('pack', 'var1', NULL::text);
    WHILE iter IS NOT NULL LOOP
        RAISE NOTICE '%', pgv_get_elem('pack', 'var1', iter, NULL::text);
        iter := pgv_next('pack', 'var1', iter);
    END LOOP;
END;
$$;

Postgres Professional, Moscow, Russia

F.52. pg_visibility

The `pg_visibility` module provides a means for examining the visibility map (VM) and page-level visibility information of a table. It also provides functions to check the integrity of a visibility map and to force it to be rebuilt.

Three different bits are used to store information about page-level visibility. The all-visible bit in the visibility map indicates that every tuple in the corresponding page of the relation is visible to every current and future transaction. The all-frozen bit in the visibility map indicates that every tuple in the page is frozen; that is, no future vacuum will need to modify the page until such time as a tuple is inserted, updated, deleted, or locked on that page. The page header's `PD_ALL_VISIBLE` bit has the same meaning as the all-visible bit in the visibility map, but is stored within the data page itself rather than in a separate data structure. These two bits will normally agree, but the page's all-visible bit can sometimes be set while the visibility map bit is clear after a crash recovery. The reported values can also disagree because of a change that occurs after `pg_visibility` examines the visibility map and before it examines the data page. Any event that causes data corruption can also cause these bits to disagree.

Functions that display information about `PD_ALL_VISIBLE` bits are much more costly than those that only consult the visibility map, because they must read the relation's data blocks rather than only the (much smaller) visibility map. Functions that check the relation's data blocks are similarly expensive.

F.52.1. Functions

`pg_visibility_map(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation.

`pg_visibility(relation regclass, blkno bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns record

Returns the all-visible and all-frozen bits in the visibility map for the given block of the given relation, plus the `PD_ALL_VISIBLE` bit of that block.

`pg_visibility_map(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation.

`pg_visibility(relation regclass, blkno OUT bigint, all_visible OUT boolean, all_frozen OUT boolean, pd_all_visible OUT boolean)` returns setof record

Returns the all-visible and all-frozen bits in the visibility map for each block of the given relation, plus the `PD_ALL_VISIBLE` bit of each block.

`pg_visibility_map_summary(relation regclass, all_visible OUT bigint, all_frozen OUT bigint)` returns record

Returns the number of all-visible pages and the number of all-frozen pages in the relation according to the visibility map.

`pg_check_frozen(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-frozen tuples stored in pages marked all-frozen in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_check_visible(relation regclass, t_ctid OUT tid)` returns setof tid

Returns the TIDs of non-all-visible tuples stored in pages marked all-visible in the visibility map. If this function returns a non-empty set of TIDs, the visibility map is corrupt.

`pg_truncate_visibility_map(relation regclass)` returns void

Truncates the visibility map for the given relation. This function is useful if you believe that the visibility map for the relation is corrupt and wish to force rebuilding it. The first `VACUUM` executed on the given relation after this function is executed will scan every page in the relation and rebuild the visibility map. (Until that is done, queries will treat the visibility map as containing all zeroes.)

By default, these functions are executable only by superusers and members of the `pg_stat_scan_tables` role, with the exception of `pg_truncate_visibility_map(relation regclass)` which can only be executed by superusers.

F.53. `pg_wait_sampling`

`pg_wait_sampling` is a Postgres Pro extension for collecting sampling-based statistics on wait events.

Starting from the 9.6 version, Postgres Pro Enterprise provides information about the current wait events for particular processes. However, to get descriptive statistics of the server activity, you have to sample wait events multiple times. The `pg_wait_sampling` extension automates wait events sampling by launching a special background worker. With `pg_wait_sampling` enabled, you can get the following sampling-based data:

- *Waits history* — the list of wait events for recent processes, with timestamps.
- *Waits profile* — the number of wait event samples for all processes over time, per wait event type.
- Current wait events for all processes, including background workers.

Using `pg_wait_sampling`, you can troubleshoot dependencies for queries that take longer than expected. You can see what a particular process is waiting for at each moment of time, and analyze wait events statistics. For the list of possible wait events, see [Table 27.4](#).

See Also

[Viewing Statistics on Wait Events](#)

[Reference](#)

F.53.1. Installation

The `pg_wait_sampling` extension is included into Postgres Pro Enterprise and requires no special pre-requisites.

To enable `pg_wait_sampling`, do the following:

1. Add `pg_wait_sampling` to the `shared_preload_libraries` variable in the `postgresql.conf` file:

```
shared_preload_libraries = 'pg_wait_sampling'
```

2. Create the `pg_wait_sampling` extension using the following query:

```
CREATE EXTENSION pg_wait_sampling;
```

3. Restart the server. Since `pg_wait_sampling` requires additional shared memory and launches a background worker, you must restart the server after adding or removing `pg_wait_sampling`.

Once the extension is created, `pg_wait_sampling` starts collecting statistics on wait events for each process. Optionally, you can change the sampling frequency and configure statistics collection modes using [GUC variables](#).

If you want to stop collecting statistics, drop the `pg_wait_sampling` extension, remove the `pg_wait_sampling` from the `shared_preload_libraries` variable, and restart the server again.

F.53.2. Usage

F.53.2.1. Viewing Statistics on Wait Events

When `pg_wait_sampling` is enabled, wait events are sampled each 10ms by default. You can access the collected statistics through a set of functions and views. If some of your queries appear stalled or take longer than expected, you can review all the current wait events in the `pg_wait_sampling_current` view:

```
SELECT * FROM pg_wait_sampling_current;
```

The returned statistics covers all the active processes, including background workers. To filter the view for a single process, run `pg_wait_sampling_get_current()` function specifying the process ID:

```
SELECT * FROM pg_wait_sampling_get_current(pid);
```

To better understand the dynamics of the recent wait events, you can access the `pg_wait_sampling_history` view that provides the wait events history for the latest processes:

```
SELECT * FROM pg_wait_sampling_history;
```

The returned view displays wait samples per process, with event timestamps. Waits history is implemented as an in-memory ring buffer. By default, the history size is limited to 5000 samples. To save history for a longer period of time, you can modify the `pg_wait_sampling.history_size` variable, or connect a client application to periodically read waits history and dump it to a local storage.

To monitor wait events in your database over time, use the `pg_wait_sampling_profile` view:

```
SELECT * FROM pg_wait_sampling_profile;
```

Waits profile is stored as an in-memory hash table that accumulates samples per each process and each wait event. You can reset waits profile by calling the `pg_wait_sampling_reset_profile()` function. If you connect a client to your database that periodically dumps the wait events data and resets the profile, you can save and compare statistics of wait events intensity over time.

Important

Since wait sampling statistics is stored in RAM, make sure to reset the waits profile from time to time to avoid memory overflow.

If you are not interested in the distribution of wait events between processes, you can set the `pg_wait_sampling.profile_pid` variable to `false`. In this case, the `pid` value for each process is set to zero, and wait samples for all the processes are stored together.

F.53.3. Reference

F.53.3.1. GUC Variables

The `pg_wait_sampling` extension is configured with GUC variables. You must have superuser rights to change GUC variables. Since these variables are placed into shared memory, you can change them from any backend that affects the `pg_wait_sampling` background worker runtime.

`pg_wait_sampling.history_size (int4)`

Size of in-memory ring buffer for history sampling, in the number of samples.

Default: 5000

`pg_wait_sampling.history_period (int4)`

Time interval for history sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_period (int4)`

Time interval for waits profile sampling, in milliseconds.

Default: 10

`pg_wait_sampling.profile_pid (bool)`

Sampling mode for waits profile. If set to `true`, waits profile is collected per process. If you set `pg_wait_sampling.profile_pid` to `false`, waits profile is collected for all processes together. In this case, the `pid` value for each process is set to zero, and the corresponding row contains wait samples for all the processes.

Default: `true`

`pg_wait_sampling.profile_queries (bool)`

Sampling mode for waits profile. If set to `false`, waits profile is collected for all queries together. In this case, the `queryid` value for each query is set to zero, and the corresponding row contains wait samples for all the queries. To collect waits profile per query, ensure that the [pg_stat_statements](#) extension is configured and set `pg_wait_sampling.profile_queries` to `true`.

Default: `true`

F.53.3.2. `pg_wait_sampling` Views

F.53.3.2.1. `pg_wait_sampling_current` View

The `pg_wait_sampling_current` view provides the information about the current wait events for all processes, including background workers.

Table F.111. `pg_wait_sampling_current` View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID
<code>event_type</code>	<code>text</code>	Name of wait event type
<code>event</code>	<code>text</code>	Name of wait event
<code>queryid</code>	<code>int8</code>	Query ID

F.53.3.2.2. `pg_wait_sampling_history` View

The `pg_wait_sampling_history` view provides the history of wait events. This data is stored as an in-memory ring buffer.

Table F.112. `pg_wait_sampling_history` View

Column Name	Column Type	Description
<code>pid</code>	<code>int4</code>	Process ID
<code>ts</code>	<code>timestampz</code>	Sample timestamp
<code>event_type</code>	<code>text</code>	Name of wait event type
<code>event</code>	<code>text</code>	Name of wait event
<code>queryid</code>	<code>int8</code>	Query ID

F.53.3.2.3. `pg_wait_sampling_profile` View

The `pg_wait_sampling_profile` view provides the profile of wait events. This data is stored as an in-memory hash table.

Table F.113. pg_wait_sampling_profile View

Column Name	Column Type	Description
pid	int4	Process ID
event_type	text	Name of wait event type
event	text	Name of wait event
queryid	int8	Query ID
count	int8	Number of samples

F.53.3.3. Functions

`pg_wait_sampling_get_current(pid int4)`

Returns the `pg_wait_sampling_current` view with the list of current wait events. If you set the `pid` argument, the view is filtered for the process with this `pid`.

Arguments:

- `pid` — Optional. The process ID for which to display the current wait events.

`pg_wait_sampling_reset_profile()`

Resets the waits profile and clears the memory.

F.53.4. Author

Alexander Korotkov

F.54. plantuner

The `plantuner` module provides hints for the planner that can disable or enable indexes for query execution.

F.54.1. Motivation

In some cases, it may be required to control the planner by providing hints that make the optimizer ignore some parts of its algorithm. There are many situations when a developer may want to temporarily disable specific index(es), without dropping them, or to instruct the planner to use a specific index.

This version of `plantuner` provides a possibility to hide the specified indexes from Postgres Pro planner, so it will not use them. For some workloads, Postgres Pro could be too pessimistic about newly created tables and assume that there are much more rows in a table than it actually has. If the `plantuner.fix_empty_table` GUC variable is set to `true`, `plantuner` sets to zero the number of pages/tuples of the table that has no blocks in a file.

F.54.2. GUC Variables

`plantuner.disable_index` — list of indexes invisible to planner.

`plantuner.enable_index` — list of indexes visible to planner even if they are hidden by `plantuner.disable_index`.

F.54.3. Example

To enable the module, you can either load `plantuner` shared library in a `psql` session or specify `shared_preload_libraries` option in `postgresql.conf`.

```
=# LOAD 'plantuner';
=# create table test(id int);
=# create index id_idx on test(id);
```

```

=# create index id_idx2 on test(id);
=# \d test
      Table "public.test"
  Column | Type      | Modifiers
-----+-----+-----
   id    | integer   |
Indexes:
    "id_idx" btree (id)
    "id_idx2" btree (id)
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx2  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set enable_seqscan=off;
=# set plantuner.disable_index='id_idx2';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)
=# set plantuner.disable_index='id_idx2,id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Seq Scan on test  (cost=10000000000.00..10000000040.00 rows=12 width=4)
  Filter: (id = 1)
(2 rows)
=# set plantuner.enable_index='id_idx';
=# explain select id from test where id=1;
               QUERY PLAN
-----
Bitmap Heap Scan on test  (cost=4.34..15.03 rows=12 width=4)
  Recheck Cond: (id = 1)
    -> Bitmap Index Scan on id_idx  (cost=0.00..4.34 rows=12 width=0)
        Index Cond: (id = 1)
(4 rows)

```

F.54.4. Authors

All work was done by Teodor Sigaev (teodor@sigaev.ru) and Oleg Bartunov (oleg@sai.msu.su).

The work sponsored by Nomao project (<http://www.nomao.com>).

F.55. postgres_fdw

The `postgres_fdw` module provides the foreign-data wrapper `postgres_fdw`, which can be used to access data stored in external Postgres Pro servers.

The functionality provided by this module overlaps substantially with the functionality of the older [dblink](#) module. But `postgres_fdw` provides more transparent and standards-compliant syntax for accessing remote tables, and can give better performance in many cases.

To prepare for remote access using `postgres_fdw`:

1. Install the `postgres_fdw` extension using `CREATE EXTENSION`.
2. Create a foreign server object, using `CREATE SERVER`, to represent each remote database you want to connect to. Specify connection information, except `user` and `password`, as options of the server object.
3. Create a user mapping, using `CREATE USER MAPPING`, for each database user you want to allow to access each foreign server. Specify the remote user name and password to use as `user` and `password` options of the user mapping.
4. Create a foreign table, using `CREATE FOREIGN TABLE` or `IMPORT FOREIGN SCHEMA`, for each remote table you want to access. The columns of the foreign table must match the referenced remote table. You can, however, use table and/or column names different from the remote table's, if you specify the correct remote names as options of the foreign table object.

Now you need only `SELECT` from a foreign table to access the data stored in its underlying remote table. You can also modify the remote table using `INSERT`, `UPDATE`, `DELETE`, or `COPY`. (Of course, the remote user you have specified in your user mapping must have privileges to do these things.)

Note that `postgres_fdw` currently lacks support for `INSERT` statements with an `ON CONFLICT DO UPDATE` clause. However, the `ON CONFLICT DO NOTHING` clause is supported, provided a unique index inference specification is omitted. Note also that `postgres_fdw` supports row movement invoked by `UPDATE` statements executed on partitioned tables, but it currently does not handle the case where a remote partition chosen to insert a moved row into is also an `UPDATE` target partition that will be updated later.

It is generally recommended that the columns of a foreign table be declared with exactly the same data types, and collations if applicable, as the referenced columns of the remote table. Although `postgres_fdw` is currently rather forgiving about performing data type conversions at need, surprising semantic anomalies may arise when types or collations do not match, due to the remote server interpreting query conditions differently from the local server.

Note that a foreign table can be declared with fewer columns, or with a different column order, than its underlying remote table has. Matching of columns to the remote table is by name, not position.

F.55.1. FDW Options of `postgres_fdw`

F.55.1.1. Connection Options

A foreign server using the `postgres_fdw` foreign data wrapper can have the same options that `libpq` accepts in connection strings, as described in [Section 35.1.2](#), except that these options are not allowed or have special handling:

- `user`, `password` and `sslpassword` (specify these in a user mapping, instead, or use a service file)
- `client_encoding` (this is automatically set from the local server encoding)
- `fallback_application_name` (always set to `postgres_fdw`)
- `sslkey` and `sslcert` - these may appear in *either or both* a connection and a user mapping. If both are present, the user mapping setting overrides the connection setting.

Only superusers may create or modify user mappings with the `sslcert` or `sslkey` settings.

Only superusers may connect to foreign servers without password authentication, so always specify the `password` option for user mappings belonging to non-superusers.

A superuser may override this check on a per-user-mapping basis by setting the user mapping option `password_required` `'false'`, e.g.,

```
ALTER USER MAPPING FOR some_non_superuser SERVER loopback_nopw
OPTIONS (ADD password_required 'false');
```

To prevent unprivileged users from exploiting the authentication rights of the unix user the postgres server is running as to escalate to superuser rights, only the superuser may set this option on a user mapping.

Care is required to ensure that this does not allow the mapped user the ability to connect as superuser to the mapped database per CVE-2007-3278 and CVE-2007-6601. Don't set `password_required=false` on the `public` role. Keep in mind that the mapped user can potentially use any client certificates, `.pgpass`, `.pg_service.conf` etc in the unix home directory of the system user the postgres server runs as. They can also use any trust relationship granted by authentication modes like `peer` or `ident` authentication.

F.55.1.2. Object Name Options

These options can be used to control the names used in SQL statements sent to the remote Postgres Pro server. These options are needed when a foreign table is created with names different from the underlying remote table's names.

`schema_name`

This option, which can be specified for a foreign table, gives the schema name to use for the foreign table on the remote server. If this option is omitted, the name of the foreign table's schema is used.

`table_name`

This option, which can be specified for a foreign table, gives the table name to use for the foreign table on the remote server. If this option is omitted, the foreign table's name is used.

`column_name`

This option, which can be specified for a column of a foreign table, gives the column name to use for the column on the remote server. If this option is omitted, the column's name is used.

F.55.1.3. Cost Estimation Options

`postgres_fdw` retrieves remote data by executing queries against remote servers, so ideally the estimated cost of scanning a foreign table should be whatever it costs to be done on the remote server, plus some overhead for communication. The most reliable way to get such an estimate is to ask the remote server and then add something for overhead — but for simple queries, it may not be worth the cost of an additional remote query to get a cost estimate. So `postgres_fdw` provides the following options to control how cost estimation is done:

`use_remote_estimate`

This option, which can be specified for a foreign table or a foreign server, controls whether `postgres_fdw` issues remote `EXPLAIN` commands to obtain cost estimates. A setting for a foreign table overrides any setting for its server, but only for that table. The default is `false`.

`fdw_startup_cost`

This option, which can be specified for a foreign server, is a numeric value that is added to the estimated startup cost of any foreign-table scan on that server. This represents the additional overhead of establishing a connection, parsing and planning the query on the remote side, etc. The default value is 100.

`fdw_tuple_cost`

This option, which can be specified for a foreign server, is a numeric value that is used as extra cost per-tuple for foreign-table scans on that server. This represents the additional overhead of data transfer between servers. You might increase or decrease this number to reflect higher or lower network delay to the remote server. The default value is 0.01.

When `use_remote_estimate` is `true`, `postgres_fdw` obtains row count and cost estimates from the remote server and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. When `use_remote_estimate` is `false`, `postgres_fdw` performs local row count and cost estimation and then adds `fdw_startup_cost` and `fdw_tuple_cost` to the cost estimates. This local estimation is unlikely to be very accurate unless local copies of the remote table's statistics are available. Running [ANALYZE](#) on the foreign table is the way to update the local statistics; this will perform a scan of the remote table and then calculate and store statistics just as though the table were local. Keeping local statistics can be a useful

way to reduce per-query planning overhead for a remote table — but if the remote table is frequently updated, the local statistics will soon be obsolete.

F.55.1.4. Remote Execution Options

By default, only `WHERE` clauses using built-in operators and functions will be considered for execution on the remote server. Clauses involving non-built-in functions are checked locally after rows are fetched. If such functions are available on the remote server and can be relied on to produce the same results as they do locally, performance can be improved by sending such `WHERE` clauses for remote execution. This behavior can be controlled using the following option:

`extensions`

This option is a comma-separated list of names of Postgres Pro extensions that are installed, in compatible versions, on both the local and remote servers. Functions and operators that are immutable and belong to a listed extension will be considered shippable to the remote server. This option can only be specified for foreign servers, not per-table.

When using the `extensions` option, *it is the user's responsibility* that the listed extensions exist and behave identically on both the local and remote servers. Otherwise, remote queries may fail or behave unexpectedly.

`fetch_size`

This option specifies the number of rows `postgres_fdw` should get in each fetch operation. It can be specified for a foreign table or a foreign server. The option specified on a table overrides an option specified for the server. The default is 100.

F.55.1.5. Updatability Options

By default all foreign tables using `postgres_fdw` are assumed to be updatable. This may be overridden using the following option:

`updatable`

This option controls whether `postgres_fdw` allows foreign tables to be modified using `INSERT`, `UPDATE` and `DELETE` commands. It can be specified for a foreign table or a foreign server. A table-level option overrides a server-level option. The default is `true`.

Of course, if the remote table is not in fact updatable, an error would occur anyway. Use of this option primarily allows the error to be thrown locally without querying the remote server. Note however that the `information_schema` views will report a `postgres_fdw` foreign table to be updatable (or not) according to the setting of this option, without any check of the remote server.

F.55.1.6. Importing Options

`postgres_fdw` is able to import foreign table definitions using `IMPORT FOREIGN SCHEMA`. This command creates foreign table definitions on the local server that match tables or views present on the remote server. If the remote tables to be imported have columns of user-defined data types, the local server must have compatible types of the same names.

Importing behavior can be customized with the following options (given in the `IMPORT FOREIGN SCHEMA` command):

`import_collate`

This option controls whether column `COLLATE` options are included in the definitions of foreign tables imported from a foreign server. The default is `true`. You might need to turn this off if the remote server has a different set of collation names than the local server does, which is likely to be the case if it's running on a different operating system. If you do so, however, there is a very severe risk that the imported table columns' collations will not match the underlying data, resulting in anomalous query behavior.

Even when this parameter is set to `true`, importing columns whose collation is the remote server's default can be risky. They will be imported with `COLLATE "default"`, which will select the local server's default collation, which could be different.

`import_default`

This option controls whether column `DEFAULT` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `false`. If you enable this option, be wary of defaults that might get computed differently on the local server than they would be on the remote server; `nextval()` is a common source of problems. The `IMPORT` will fail altogether if an imported default expression uses a function or operator that does not exist locally.

`import_generated`

This option controls whether column `GENERATED` expressions are included in the definitions of foreign tables imported from a foreign server. The default is `true`. The `IMPORT` will fail altogether if an imported generated expression uses a function or operator that does not exist locally.

`import_not_null`

This option controls whether column `NOT NULL` constraints are included in the definitions of foreign tables imported from a foreign server. The default is `true`.

Note that constraints other than `NOT NULL` will never be imported from the remote tables. Although Postgres Pro does support `CHECK` constraints on foreign tables, there is no provision for importing them automatically, because of the risk that a constraint expression could evaluate differently on the local and remote servers. Any such inconsistency in the behavior of a `CHECK` constraint could lead to hard-to-detect errors in query optimization. So if you wish to import `CHECK` constraints, you must do so manually, and you should verify the semantics of each one carefully. For more detail about the treatment of `CHECK` constraints on foreign tables, see [CREATE FOREIGN TABLE](#).

Tables or foreign tables which are partitions of some other table are automatically excluded. Partitioned tables are imported, unless they are a partition of some other table. Since all data can be accessed through the partitioned table which is the root of the partitioning hierarchy, this approach should allow access to all the data without creating extra objects.

F.55.2. Connection Management

`postgres_fdw` establishes a connection to a foreign server during the first query that uses a foreign table associated with the foreign server. This connection is kept and re-used for subsequent queries in the same session. However, if multiple user identities (user mappings) are used to access the foreign server, a connection is established for each user mapping.

F.55.3. Transaction Management

During a query that references any remote tables on a foreign server, `postgres_fdw` opens a transaction on the remote server if one is not already open corresponding to the current local transaction. The remote transaction is committed or aborted when the local transaction commits or aborts. Savepoints are similarly managed by creating corresponding remote savepoints.

The remote transaction uses `SERIALIZABLE` isolation level when the local transaction has `SERIALIZABLE` isolation level; otherwise it uses `REPEATABLE READ` isolation level. This choice ensures that if a query performs multiple table scans on the remote server, it will get snapshot-consistent results for all the scans. A consequence is that successive queries within a single transaction will see the same data from the remote server, even if concurrent updates are occurring on the remote server due to other activities. That behavior would be expected anyway if the local transaction uses `SERIALIZABLE` or `REPEATABLE READ` isolation level, but it might be surprising for a `READ COMMITTED` local transaction. A future Postgres Pro release might modify these rules.

Note that it is currently not supported by `postgres_fdw` to prepare the remote transaction for two-phase commit.

F.55.4. Remote Query Optimization

`postgres_fdw` attempts to optimize remote queries to reduce the amount of data transferred from foreign servers. This is done by sending query `WHERE` clauses to the remote server for execution, and by not retrieving table columns that are not needed for the current query. To reduce the risk of misexecution of queries, `WHERE` clauses are not sent to the remote server unless they use only data types, operators, and functions that are built-in or belong to an extension that's listed in the foreign server's `extensions` option. Operators and functions in such clauses must be `IMMUTABLE` as well. For an `UPDATE` or `DELETE` query, `postgres_fdw` attempts to optimize the query execution by sending the whole query to the remote server if there are no query `WHERE` clauses that cannot be sent to the remote server, no local joins for the query, no row-level local `BEFORE` or `AFTER` triggers or stored generated columns on the target table, and no `CHECK OPTION` constraints from parent views. In `UPDATE`, expressions to assign to target columns must use only built-in data types, `IMMUTABLE` operators, or `IMMUTABLE` functions, to reduce the risk of misexecution of the query.

When `postgres_fdw` encounters a join between foreign tables on the same foreign server, it sends the entire join to the foreign server, unless for some reason it believes that it will be more efficient to fetch rows from each table individually, or unless the table references involved are subject to different user mappings. While sending the `JOIN` clauses, it takes the same precautions as mentioned above for the `WHERE` clauses.

The query that is actually sent to the remote server for execution can be examined using `EXPLAIN VERBOSE`.

F.55.5. Remote Query Execution Environment

In the remote sessions opened by `postgres_fdw`, the `search_path` parameter is set to just `pg_catalog`, so that only built-in objects are visible without schema qualification. This is not an issue for queries generated by `postgres_fdw` itself, because it always supplies such qualification. However, this can pose a hazard for functions that are executed on the remote server via triggers or rules on remote tables. For example, if a remote table is actually a view, any functions used in that view will be executed with the restricted search path. It is recommended to schema-qualify all names in such functions, or else attach `SET search_path` options (see [CREATE FUNCTION](#)) to such functions to establish their expected search path environment.

`postgres_fdw` likewise establishes remote session settings for various parameters:

- `TimeZone` is set to `UTC`
- `DateStyle` is set to `ISO`
- `IntervalStyle` is set to `postgres`
- `extra_float_digits` is set to 3 for remote servers 9.0 and newer and is set to 2 for older versions

These are less likely to be problematic than `search_path`, but can be handled with function `SET` options if the need arises.

It is *not* recommended that you override this behavior by changing the session-level settings of these parameters; that is likely to cause `postgres_fdw` to malfunction.

F.55.6. Cross-Version Compatibility

`postgres_fdw` can be used with remote servers dating back to PostgreSQL 8.3. Read-only capability is available back to 8.1. A limitation however is that `postgres_fdw` generally assumes that immutable built-in functions and operators are safe to send to the remote server for execution, if they appear in a `WHERE` clause for a foreign table. Thus, a built-in function that was added since the remote server's release might be sent to it for execution, resulting in “function does not exist” or a similar error. This type of failure can be worked around by rewriting the query, for example by embedding the foreign table reference in a sub-`SELECT` with `OFFSET 0` as an optimization fence, and placing the problematic function or operator outside the sub-`SELECT`.

F.55.7. Examples

Here is an example of creating a foreign table with `postgres_fdw`. First install the extension:

```
CREATE EXTENSION postgres_fdw;
```

Then create a foreign server using [CREATE SERVER](#). In this example we wish to connect to a Postgres Pro server on host `192.83.123.89` listening on port `5432`. The database to which the connection is made is named `foreign_db` on the remote server:

```
CREATE SERVER foreign_server
    FOREIGN DATA WRAPPER postgres_fdw
    OPTIONS (host '192.83.123.89', port '5432', dbname 'foreign_db');
```

A user mapping, defined with [CREATE USER MAPPING](#), is needed as well to identify the role that will be used on the remote server:

```
CREATE USER MAPPING FOR local_user
    SERVER foreign_server
    OPTIONS (user 'foreign_user', password 'password');
```

Now it is possible to create a foreign table with [CREATE FOREIGN TABLE](#). In this example we wish to access the table named `some_schema.some_table` on the remote server. The local name for it will be `foreign_table`:

```
CREATE FOREIGN TABLE foreign_table (
    id integer NOT NULL,
    data text
)
    SERVER foreign_server
    OPTIONS (schema_name 'some_schema', table_name 'some_table');
```

It's essential that the data types and other properties of the columns declared in `CREATE FOREIGN TABLE` match the actual remote table. Column names must match as well, unless you attach `column_name` options to the individual columns to show how they are named in the remote table. In many cases, use of [IMPORT FOREIGN SCHEMA](#) is preferable to constructing foreign table definitions manually.

Shigeru Hanada <shigeru.hanada@gmail.com>

F.56. ptrack

PTRACK is a block-level incremental backup engine for Postgres Pro. If PTRACK is enabled, backup tools like [pg_probackup](#) can use its API to get information on the changed blocks on the fly when taking incremental backups. Copying only those blocks that have changed since the previous backup can significantly speed up the creation and minimize the size of backups.

PTRACK is designed to allow false positives, but to never allow false negatives: it means that all changes within the data directory except hint bits are guaranteed to be marked in the PTRACK map file, although some unchanged blocks might be included as well.

F.56.1. Setting up PTRACK

Once you complete Postgres Pro Enterprise installation, do the following:

1. Add `ptrack` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'ptrack'
```

2. Set [ptrack.map_size](#) parameter to a positive integer.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more

likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the incremental backup.

Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but keep in mind that you need up to `ptrack.map_size * 3` MB of additional disk space since PTRACK uses two additional temporary files to ensure durability. It is not recommended to set this parameter to a value higher than 1024. Even for Postgres Pro clusters with $N > 1$ TB, it makes sense to use a higher value only if the efficiency and sizes of backups are more critical than the potential overhead of maintaining a large PTRACK map.

3. Check the `wal_level` setting. When using PTRACK, it is required to set the `wal_level` parameter to `replica` or higher. Otherwise, you can lose some tracked changes if crash-recovery occurs: some commands do not write WAL at all if `wal_level` is `minimal`, and PTRACK map files are flushed to disk only at checkpoint time.
4. Restart the Postgres Pro Enterprise instance for the changes to take effect, and then create the PTRACK extension:

```
CREATE EXTENSION ptrack;
```

As a result, several PTRACK functions are created, which are required for accessing PTRACK data.

Once this setup is complete, PTRACK starts tracking all the page changes in the Postgres Pro cluster and creates a `ptrack.map` file that stores the latest LSN values for these pages.

Note

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

F.56.2. PTRACK Configuration Parameters

`ptrack.map_size (integer)`

Specifies the size of a PTRACK map file and the amount of shared memory allocated for this file, in MB. The PTRACK map file stores the latest LSN values for all pages of the Postgres Pro cluster that have changed since PTRACK was enabled. It is not recommended to set this parameter to a value higher than 1GB. The -1 value disables PTRACK, while the 0 value both disables PTRACK and cleans up all the related service files.

The `ptrack.map_size` parameter can only be set at server start. If you change this parameter, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. To avoid losing recent changes, it is recommended to retake a full backup after modifying this setting.

Default: -1

F.56.3. PTRACK Functions

`ptrack_init_lsn()` returns `pg_lsn`

Returns the LSN of the last PTRACK map initialization.

`ptrack_get_pagemapset(start_lsn pg_lsn)` returns `setof record`

Returns a list of data files changed since the specified `start_lsn` with the number and bitmap of changed pages for each file.

For example:

```
postgres=# SELECT * FROM ptrack_get_pagemapset('0/185C8C0');
      path      | pagecount |          pagemap
-----+-----+-----
base/16384/1255 |         3 | \x00100000000050000000000000
base/16384/2674 |         3 | \x0000000900010000000000000000
base/16384/2691 |         1 | \x0000400000000000000000000000
base/16384/2608 |         1 | \x00000000000000004000000000000000
base/16384/2690 |         1 | \x00040000000000000000000000
```

`ptrack_get_change_stat(start_lsn pg_lsn)` returns record

Returns the statistics of changes (number of files, number of changed pages and their total size in MB) since the specified `start_lsn`.

For example:

```
postgres=# SELECT * FROM ptrack_get_change_stat('0/285C8C8');
  files | pages |      size, MB
-----+-----+-----
    20 |    25 | 0.19531250000000000000
```

`ptrack_version()` returns text

Returns PTRACK version.

F.57. referee

`referee` is a Postgres Pro Enterprise extension for managing quorum settings in clusters with an even number of nodes configured with [multimaster](#). Installed on a separate system, the `referee` extension provides a voting node to assign the quorum status to a subset of nodes if only half of the cluster nodes remain connected to each other.

If a multi-master cluster is split into equal parts, or half of the cluster nodes fail, each subset of nodes that equals half of the cluster tries to access the referee. The first subset that gets connected to the referee wins the voting and continues working, while all the other nodes are excluded from the cluster to avoid split-brain problems.

The referee node does not store any cluster data, so it is very lightweight and can be located on systems with limited resources. For details on how to set up and use a referee node with `multimaster`, see [Section F.30.3.3](#).

Postgres Professional, Moscow, Russia

F.58. rum

F.58.1. Introduction

The **rum** module provides access method to work with the RUM indexes. It is based on the GIN access methods code.

GIN index allows to perform fast full-text search using `tsvector` and `tsquery` types. However, full-text search with GIN index has the following drawbacks:

- Slow ranking. Ranking requires positional information, but GIN index does not store positions of lexemes. So after the index scan we need an additional heap scan to retrieve lexeme positions.
- Slow phrase search. This problem is related to the previous one as phrase search also needs positional information.
- Slow ordering by timestamp. GIN index cannot store any additional information together with lexemes, so it is necessary to perform a heap scan.

RUM solves these issues by storing additional information in posting tree. In particular, it stores positional information of lexemes or timestamps.

The drawback of RUM is that it has slower build and insert time as compared to GIN because RUM stores additional information together with keys and uses generic WAL records.

F.58.2. Installation

rum is a Postgres Pro Enterprise extension and it has no special prerequisites.

Install extension as follows:

```
$ psql dbname -c "CREATE EXTENSION rum"
```

F.58.3. Common Operators

The operators provided by the rum module are shown in [Table F.114](#):

Table F.114. rum Operators

Operator	Returns	Description
tsvector <=> tsquery	float4	Returns distance between tsvector and tsquery values.
timestamp <=> timestamp	float8	Returns distance between two timestamp values.
timestamp <= timestamp	float8	Returns distance only for ascending timestamp values.
timestamp => timestamp	float8	Returns distance only for descending timestamp values.

F.58.4. Operator Classes

The rum extension provides the following operator classes:

rum_tsvector_ops

Stores tsvector lexemes with positional information. Supports ordering by <=> operator and prefix search.

rum_tsvector_hash_ops

Stores hash of tsvector lexemes with positional information. Supports ordering by <=> operator, but does not support prefix search.

rum_tsvector_addon_ops

Stores tsvector lexemes with additional data of any type supported by RUM.

rum_tsvector_hash_addon_ops

Stores tsvector lexemes with additional data of any type supported by RUM. Does not support prefix search.

rum_tsquery_ops

Stores branches of query tree in additional information.

rum_anyarray_ops

Stores anyarray elements with length of the array. Supports ordering by <=> operator.

Indexable operators: && @> <@ = %

`rum_anyarray_addon_ops`

Stores `anyarray` elements with additional data of any type supported by RUM.

`rum_type_ops`

Stores lexemes of the corresponding type with positional information. The *type* placeholder in the class name must be substituted by one of the following type names: `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`, `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

`rum_type_ops` supports ordering by `<=>`, `<=|`, and `|=>` operators. This operator class can be used together with `rum_tsvector_addon_ops`, `rum_tsvector_hash_addon_ops`, and `rum_anyarray_addon_ops` operator classes.

Supported indexable operators depend on the data type:

- `<` `<=` `=` `>=` `>` `<=>` `<=|` `|=>` are supported for `int2`, `int4`, `int8`, `float4`, `float8`, `money`, `oid`, `timestamp`, `timestampz`.
- `<` `<=` `=` `>=` `>` are supported for `time`, `timetz`, `date`, `interval`, `macaddr`, `inet`, `cidr`, `text`, `varchar`, `char`, `bytea`, `bit`, `varbit`, `numeric`.

Note

The following operator classes are now deprecated: `rum_tsvector_timestamp_ops`, `rum_tsvector_timestampz_ops`, `rum_tsvector_hash_timestamp_ops`, `rum_tsvector_hash_timestampz_ops`.

F.58.5. Examples

F.58.5.1. `rum_tsvector_ops` Example

Let's assume we have the following table:

```
CREATE TABLE test_rum(t text, a tsvector);

CREATE TRIGGER tsvectorupdate
BEFORE UPDATE OR INSERT ON test_rum
FOR EACH ROW EXECUTE PROCEDURE tsvector_update_trigger('a', 'pg_catalog.english', 't');

INSERT INTO test_rum(t) VALUES ('The situation is most beautiful');
INSERT INTO test_rum(t) VALUES ('It is a beautiful');
INSERT INTO test_rum(t) VALUES ('It looks like a beautiful place');
```

Then we can create a new index:

```
CREATE INDEX rumidx ON test_rum USING rum (a rum_tsvector_ops);
```

And we can execute the following queries:

```
SELECT t, a <=> to_tsquery('english', 'beautiful | place') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'beautiful | place')
ORDER BY a <=> to_tsquery('english', 'beautiful | place');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It is a beautiful              | 0.0303964
It looks like a beautiful place | 0.0607927
(3 rows)
```

```

SELECT t, a <=> to_tsquery('english', 'place | situation') AS rank
FROM test_rum
WHERE a @@ to_tsquery('english', 'place | situation')
ORDER BY a <=> to_tsquery('english', 'place | situation');
      t              | rank
-----+-----
The situation is most beautiful | 0.0303964
It looks like a beautiful place | 0.0303964
(2 rows)

```

F.58.5.2. rum_tsvector_addon_ops Example

Let's assume we have the following table:

```

CREATE TABLE tsts (id int, t tsvector, d timestamp);

\copy tsts from 'rum/data/tsts.data'

CREATE INDEX tsts_idx ON tsts USING rum (t rum_tsvector_addon_ops, d)
WITH (attach = 'd', to = 't');

```

Now we can execute the following queries:

```

EXPLAIN (costs off)
  SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d
  <=> '2016-05-16 14:21:25' LIMIT 5;
                                QUERY PLAN
-----
Limit
->  Index Scan using tsts_idx on tsts
      Index Cond: (t @@ '''wr''' & '''qh''':tsquery)
      Order By: (d <=> 'Mon May 16 14:21:25 2016':timestamp without time zone)
(4 rows)

SELECT id, d, d <=> '2016-05-16 14:21:25' FROM tsts WHERE t @@ 'wr&qh' ORDER BY d <=>
'2016-05-16 14:21:25' LIMIT 5;
 id | d | ?column?
-----+-----+-----
355 | Mon May 16 14:21:22.326724 2016 | 2.673276
354 | Mon May 16 13:21:22.326724 2016 | 3602.673276
371 | Tue May 17 06:21:22.326724 2016 | 57597.326724
406 | Wed May 18 17:21:22.326724 2016 | 183597.326724
415 | Thu May 19 02:21:22.326724 2016 | 215997.326724
(5 rows)

```

F.58.5.3. rum_tsquery_ops Example

Suppose we have the table:

```

CREATE TABLE query (q tsquery, tag text);

INSERT INTO query VALUES ('supernova & star', 'sn'),
  ('black', 'color'),
  ('big & bang & black & hole', 'bang'),
  ('spiral & galaxy', 'shape'),
  ('black & hole', 'color');

CREATE INDEX query_idx ON query USING rum(q);

```

We can execute the following fast query:

```
SELECT * FROM query
  WHERE to_tsvector('black holes never exists before we think about them') @@ q;
      q      | tag
-----+-----
'black'      | color
'black' & 'hole' | color
(2 rows)
```

F.58.5.4. rum_anyarray_ops Example

Let's assume we have the following table:

```
CREATE TABLE test_array (i int2[]);

INSERT INTO test_array VALUES ('{}'), ('{0}'), ('{1,2,3,4}'), ('{1,2,3}'), ('{1,2}'),
 ('{1}');

CREATE INDEX idx_array ON test_array USING rum (i rum_anyarray_ops);
```

Now we can execute the following query using index scan:

```
SET enable_seqscan TO off;

EXPLAIN (COSTS OFF) SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      QUERY PLAN
-----
Index Scan using idx_array on test_array
  Index Cond: (i && '{1}'::smallint[])
  Order By: (i <=> '{1}'::smallint[])
(3 rows)

SELECT * FROM test_array WHERE i && '{1}' ORDER BY i <=> '{1}' ASC;
      i
-----
{1}
{1,2}
{1,2,3}
{1,2,3,4}
(4 rows)
```

F.59. seg

This module implements a data type `seg` for representing line segments, or floating point intervals. `seg` can represent uncertainty in the interval endpoints, making it especially useful for representing laboratory measurements.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.59.1. Rationale

The geometry of measurements is usually more complex than that of a point in a numeric continuum. A measurement is usually a segment of that continuum with somewhat fuzzy limits. The measurements

come out as intervals because of uncertainty and randomness, as well as because the value being measured may naturally be an interval indicating some condition, such as the temperature range of stability of a protein.

Using just common sense, it appears more convenient to store such data as intervals, rather than pairs of numbers. In practice, it even turns out more efficient in most applications.

Further along the line of common sense, the fuzziness of the limits suggests that the use of traditional numeric data types leads to a certain loss of information. Consider this: your instrument reads 6.50, and you input this reading into the database. What do you get when you fetch it? Watch:

```
test=> select 6.50 :: float8 as "pH";
      pH
----
6.5
(1 row)
```

In the world of measurements, 6.50 is not the same as 6.5. It may sometimes be critically different. The experimenters usually write down (and publish) the digits they trust. 6.50 is actually a fuzzy interval contained within a bigger and even fuzzier interval, 6.5, with their center points being (probably) the only common feature they share. We definitely do not want such different data items to appear the same.

Conclusion? It is nice to have a special data type that can record the limits of an interval with arbitrarily variable precision. Variable in the sense that each data element records its own precision.

Check this out:

```
test=> select '6.25 .. 6.50'::seg as "pH";
      pH
-----
6.25 .. 6.50
(1 row)
```

F.59.2. Syntax

The external representation of an interval is formed using one or two floating-point numbers joined by the range operator (`..` or `...`). Alternatively, it can be specified as a center point plus or minus a deviation. Optional certainty indicators (`<`, `>` or `~`) can be stored as well. (Certainty indicators are ignored by all the built-in operators, however.) [Table F.115](#) gives an overview of allowed representations; [Table F.116](#) shows some examples.

In [Table F.115](#), *x*, *y*, and *delta* denote floating-point numbers. *x* and *y*, but not *delta*, can be preceded by a certainty indicator.

Table F.115. `seg` External Representations

<i>x</i>	Single value (zero-length interval)
<i>x</i> .. <i>y</i>	Interval from <i>x</i> to <i>y</i>
<i>x</i> (+-) <i>delta</i>	Interval from <i>x</i> - <i>delta</i> to <i>x</i> + <i>delta</i>
<i>x</i> ..	Open interval with lower bound <i>x</i>
.. <i>x</i>	Open interval with upper bound <i>x</i>

Table F.116. Examples of Valid `seg` Input

5.0	Creates a zero-length segment (a point, if you will)
~5.0	Creates a zero-length segment and records ~ in the data. ~ is ignored by <code>seg</code> operations, but is preserved as a comment.
<5.0	Creates a point at 5.0. < is ignored but is preserved as a comment.

<code>>5.0</code>	Creates a point at 5.0. <code>></code> is ignored but is preserved as a comment.
<code>5 (+-) 0.3</code>	Creates an interval 4.7 .. 5.3. Note that the <code>(+-)</code> notation isn't preserved.
<code>50 ..</code>	Everything that is greater than or equal to 50
<code>.. 0</code>	Everything that is less than or equal to 0
<code>1.5e-2 .. 2E-2</code>	Creates an interval 0.015 .. 0.02
<code>1 ... 2</code>	The same as <code>1...2</code> , or <code>1 .. 2</code> , or <code>1..2</code> (spaces around the range operator are ignored)

Because the `...` operator is widely used in data sources, it is allowed as an alternative spelling of the `..` operator. Unfortunately, this creates a parsing ambiguity: it is not clear whether the upper bound in `0...23` is meant to be `23` or `0.23`. This is resolved by requiring at least one digit before the decimal point in all numbers in `seg` input.

As a sanity check, `seg` rejects intervals with the lower bound greater than the upper, for example `5 .. 2`.

F.59.3. Precision

`seg` values are stored internally as pairs of 32-bit floating point numbers. This means that numbers with more than 7 significant digits will be truncated.

Numbers with 7 or fewer significant digits retain their original precision. That is, if your query returns `0.00`, you will be sure that the trailing zeroes are not the artifacts of formatting: they reflect the precision of the original data. The number of leading zeroes does not affect precision: the value `0.0067` is considered to have just 2 significant digits.

F.59.4. Usage

The `seg` module includes a GiST index operator class for `seg` values. The operators supported by the GiST operator class are shown in [Table F.117](#).

Table F.117. Seg GiST Operators

Operator	Description
<code>seg << seg → boolean</code>	Is the first <code>seg</code> entirely to the left of the second? <code>[a, b] << [c, d]</code> is true if <code>b < c</code> .
<code>seg >> seg → boolean</code>	Is the first <code>seg</code> entirely to the right of the second? <code>[a, b] >> [c, d]</code> is true if <code>a > d</code> .
<code>seg &< seg → boolean</code>	Does the first <code>seg</code> not extend to the right of the second? <code>[a, b] &< [c, d]</code> is true if <code>b <= d</code> .
<code>seg &> seg → boolean</code>	Does the first <code>seg</code> not extend to the left of the second? <code>[a, b] &> [c, d]</code> is true if <code>a >= c</code> .
<code>seg = seg → boolean</code>	Are the two <code>segs</code> equal?
<code>seg && seg → boolean</code>	Do the two <code>segs</code> overlap?
<code>seg @> seg → boolean</code>	Does the first <code>seg</code> contain the second?
<code>seg <@ seg → boolean</code>	Is the first <code>seg</code> contained in the second?

(Before PostgreSQL 8.2, the containment operators `@>` and `<@` were respectively called `@` and `~`. These names are still available, but are deprecated and will eventually be retired. Notice that the old names are reversed from the convention formerly followed by the core geometric data types!)

In addition to the above operators, the usual comparison operators shown in [Table 9.1](#) are available for type `seg`. These operators first compare (a) to (c), and if these are equal, compare (b) to (d). That results in reasonably good sorting in most cases, which is useful if you want to use `ORDER BY` with this type.

F.59.5. Notes

For examples of usage, see the regression test `sql/seg.sql`.

The mechanism that converts `(+-)` to regular ranges isn't completely accurate in determining the number of significant digits for the boundaries. For example, it adds an extra digit to the lower boundary if the resulting interval includes a power of ten:

```
postgres=> select '10(+-)1'::seg as seg;
      seg
-----
9.0 .. 11          -- should be: 9 .. 11
```

The performance of an R-tree index can largely depend on the initial order of input values. It may be very helpful to sort the input table on the `seg` column; see the script `sort-segments.pl` for an example.

F.59.6. Credits

Original author: Gene Selkov, Jr. <selkovjr@mcs.anl.gov>, Mathematics and Computer Science Division, Argonne National Laboratory.

My thanks are primarily to Prof. Joe Hellerstein (<https://dsf.berkeley.edu/jmh/>) for elucidating the gist of the GiST (<http://gist.cs.berkeley.edu/>). I am also grateful to all Postgres developers, present and past, for enabling myself to create my own world and live undisturbed in it. And I would like to acknowledge my gratitude to Argonne Lab and to the U.S. Department of Energy for the years of faithful support of my database research.

F.60. shared_ispell

The `shared_ispell` module provides a shared ispell dictionary, i.e. a dictionary that's stored in shared segment. The traditional ispell implementation means that each session initializes and stores the dictionary on it's own, which means a lot of CPU/RAM is wasted.

This extension allocates an area in shared segment (you have to choose the size in advance) and then loads the dictionary into it when it's used for the first time.

F.60.1. Functions

The functions provided by the `shared_ispell` module are shown in [Table F.118](#).

Table F.118. `shared_ispell` Functions

Function	Returns	Description
<code>shared_ispell_reset()</code>	<code>void</code>	Resets the dictionaries (e.g. so that you can reload the updated files from disk). The sessions that already use the dictionaries will be forced to reinitialize them.
<code>shared_ispell_mem_used()</code>	<code>int</code>	Returns a value of used memory of the shared segment by loaded shared dictionaries in bytes.

Function	Returns	Description
<code>shared_ispell_mem_available()</code>	int	Returns a value of available memory of the shared segment.
<code>shared_ispell_dicts()</code>	<code>setof(dict_name varchar, affix_name varchar, words int, affixes int, bytes int)</code>	Returns a list of dictionaries loaded in the shared segment.
<code>shared_ispell_stoplists()</code>	<code>setof(stop_name varchar, words int, bytes int)</code>	Returns a list of stopwords loaded in the shared segment.

F.60.2. GUC Parameters

`shared_ispell.max_size (int)`

Defines the maximum size of the shared segment. This is a hard limit, the shared segment is not extensible and you need to set it so that all the dictionaries fit into it and not much memory is wasted.

F.60.3. Using the dictionary

The module needs to allocate space in the shared memory segment. So add this to the config file (or update the current values):

```
# libraries to load
shared_preload_libraries = 'shared_ispell'

# config of the shared memory
shared_ispell.max_size = 32MB
```

To find out how much memory you actually need, use a large value (e.g. 200MB) and load all the dictionaries you want to use. Then use the `shared_ispell_mem_used()` function to find out how much memory was actually used (and set the `shared_ispell.max_size` GUC variable accordingly).

Don't set it exactly to that value, leave there some free space, so that you can reload the dictionaries without changing the GUC `max_size` limit (which requires a restart of the DB). Something like 512kB should be just fine.

The extension defines a `shared_ispell` template that you may use to define custom dictionaries. E.g. you may do this:

```
CREATE TEXT SEARCH DICTIONARY english_shared (
    TEMPLATE = shared_ispell,
    DictFile = en_us,
    AffFile = en_us,
    StopWords = english
);

CREATE TEXT SEARCH CONFIGURATION public.english_shared
( COPY = pg_catalog.simple );

ALTER TEXT SEARCH CONFIGURATION english_shared
ALTER MAPPING FOR asciiword, asciihword, hword_asciipart,
                word, hword, hword_part
WITH english_shared, english_stem;
```

We can test created configuration:

```
SELECT * FROM ts_debug('english_shared', 'abilities');
 alias | description | token | dictionaries | dictionary
| lexemes
```

```
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
+-----+-----+
asciword | Word, all ASCII | abilities | {english_shared,english_stem} |
english_shared | {ability}
(1 row)
```

Or you can update your own text search configuration. For example, you have the `public.english` dictionary. You can update it to use the `shared_ispell` template:

```
ALTER TEXT SEARCH CONFIGURATION public.english
    ALTER MAPPING FOR asciword, asciihword, hword_asciipart,
                        word, hword, hword_part
    WITH english_shared, english_stem;
```

F.61. spi

The `spi` module provides several workable examples of using the [Server Programming Interface](#) (SPI) and triggers. While these functions are of some value in their own right, they are even more useful as examples to modify for your own purposes. The functions are general enough to be used with any table, but you have to specify table and field names (as described below) while creating a trigger.

Each of the groups of functions described below is provided as a separately-installable extension.

F.61.1. refint — Functions for Implementing Referential Integrity

`check_primary_key()` and `check_foreign_key()` are used to check foreign key constraints. (This functionality is long since superseded by the built-in foreign key mechanism, of course, but the module is still useful as an example.)

`check_primary_key()` checks the referencing table. To use, create a `BEFORE INSERT OR UPDATE` trigger using this function on a table referencing another table. Specify as the trigger arguments: the referencing table's column name(s) which form the foreign key, the referenced table name, and the column names in the referenced table which form the primary/unique key. To handle multiple foreign keys, create a trigger for each reference.

`check_foreign_key()` checks the referenced table. To use, create a `BEFORE DELETE OR UPDATE` trigger using this function on a table referenced by other table(s). Specify as the trigger arguments: the number of referencing tables for which the function has to perform checking, the action if a referencing key is found (`cascade` — to delete the referencing row, `restrict` — to abort transaction if referencing keys exist, `setnull` — to set referencing key fields to null), the triggered table's column names which form the primary/unique key, then the referencing table name and column names (repeated for as many referencing tables as were specified by first argument). Note that the primary/unique key columns should be marked `NOT NULL` and should have a unique index.

There are examples in `refint.example`.

F.61.2. autoinc — Functions for Autoincrementing Fields

`autoinc()` is a trigger that stores the next value of a sequence into an integer field. This has some overlap with the built-in “serial column” feature, but it is not the same: `autoinc()` will override attempts to substitute a different field value during inserts, and optionally it can be used to increment the field during updates, too.

To use, create a `BEFORE INSERT` (or optionally `BEFORE INSERT OR UPDATE`) trigger using this function. Specify two trigger arguments: the name of the integer column to be modified, and the name of the sequence object that will supply values. (Actually, you can specify any number of pairs of such names, if you'd like to update more than one autoincrementing column.)

There is an example in `autoinc.example`.

F.61.3. `insert_username` — Functions for Tracking Who Changed a Table

`insert_username()` is a trigger that stores the current user's name into a text field. This can be useful for tracking who last modified a particular row within a table.

To use, create a `BEFORE INSERT` and/or `UPDATE` trigger using this function. Specify a single trigger argument: the name of the text column to be modified.

There is an example in `insert_username.example`.

F.61.4. `moddatetime` — Functions for Tracking Last Modification Time

`moddatetime()` is a trigger that stores the current time into a `timestamp` field. This can be useful for tracking the last modification time of a particular row within a table.

To use, create a `BEFORE UPDATE` trigger using this function. Specify a single trigger argument: the name of the column to be modified. The column must be of type `timestamp` or `timestamp with time zone`.

There is an example in `moddatetime.example`.

F.62. `sr_plan`

Important

The `sr_plan` extension is no longer supported in Postgres Pro.

F.62.1. Rationale

`sr_plan` is an extension which allows to save query execution plans and use these plans for all repetitions of same query, instead of optimizing identical query again and again.

`sr_plan` looks like Oracle Outline system. It can be used to lock the execution plan. It is necessary if you do not trust the planner or able to form a better plan.

Typically, DBA would play with queries interactively, and save their plans and then enable use of saved plans for the queries, where predictable response time is essential.

Then application which uses these queries would use saved plans.

F.62.2. Installation

In your db:

```
CREATE EXTENSION sr_plan;
```

and modify your `postgresql.conf`:

```
shared_preload_libraries = 'sr_plan'
```

It is essential that library is preloaded during server startup, because use of saved plans is enabled on per-database basis and doesn't require any per-connection actions.

F.62.3. Usage

If you want to save the query plan is necessary to set the variable:

```
set sr_plan.write_mode = true;
```

Now plans for all subsequent queries will be stored in the table `sr_plans`, until this variable is set to false. Don't forget that all queries will be stored including duplicates. Making an example query:

```
select query_hash from sr_plans where query_hash=10;
```

Disable saving the query:

```
set sr_plan.write_mode = false;
```

Now verify that your query is saved:

```
select query_hash, enable, valid, query, explain_jsonb_plan(plan) from sr_plans;
```

query_hash	enable	valid	query
1783086253	f	t	select query_hash from sr_plans where query_hash=10;
			Bitmap Heap Scan on sr_plans
			Recheck Cond: (query_hash = 10)
			-> Bitmap Index Scan on sr_plans_query_hash_idx+
			Index Cond: (query_hash = 10)

Note use of `explain_jsonb_plan` function, that allows you to visualize execution plan in the similar way as `EXPLAIN` command does.

In the database plans are stored as jsonb. By default, all the newly saved plans are disabled, you need enable it manually:

To enable use of the saved plan

```
update sr_plans set enable=true where query_hash=1783086253;
```

(1783086253 for example only) After that, the plan for the query will be taken from the `sr_plans` table.

In addition sr plan allows you to save a parameterized query plan. In this case, we have some constants in the query that, as we know, do not affect plan.

During plan saving mode we can mark these constants as query parameters using a special function `_p` (anyelement). For example:

```
=>create table test_table (a numeric, b text);
CREATE TABLE
=>insert into test_table values (1,'1'), (2,'2'), (3,'3');
INSERT 0 3
=> set sr_plan.write_mode = true;
SET
=> select a,b from test_table where a = _p(1);
 a | b
---+---
 1 | 1
(1 row)

=> set sr_plan.write_mode = false;
SET
```

Now plan for query from our table is saved with parameter. So, if we enable saved plan in this table, this plan would be used for query with any value for a, as long as this value is wrapped with `_p()` function.

```
=>update sr_plans set enable = true where query=
      'select a,b from test_table where a = _p(1)';
UPDATE 1
-- These queries would use saved plan

=>select a,b from test_table where a = _p(2);
 a | b
---+---
 2 | 2
(1 row)

=>select a,b from test_table where a = _p(3);
 a | b
---+---
 3 | 3
(1 row)

-- This query wouldn't use saved plan, because constant is not wrapped
-- with _p()

=>select a,b from test_table where a = 1;
 a | b
---+---
 1 | 1
(1 row)
```

F.63. sslinfo

The `sslinfo` module provides information about the SSL certificate that the current client provided when connecting to Postgres Pro. The module is useless (most functions will return NULL) if the current connection does not use SSL.

Some of the information available through this module can also be obtained using the built-in system view `pg_stat_ssl`.

This extension won't build at all unless the installation was configured with `--with-openssl`.

F.63.1. Functions Provided

`ssl_is_used()` returns boolean

Returns true if current connection to server uses SSL, and false otherwise.

`ssl_version()` returns text

Returns the name of the protocol used for the SSL connection (e.g., TLSv1.0, TLSv1.1, or TLSv1.2).

`ssl_cipher()` returns text

Returns the name of the cipher used for the SSL connection (e.g., DHE-RSA-AES256-SHA).

`ssl_client_cert_present()` returns boolean

Returns true if current client has presented a valid SSL client certificate to the server, and false otherwise. (The server might or might not be configured to require a client certificate.)

`ssl_client_serial()` returns numeric

Returns serial number of current client certificate. The combination of certificate serial number and certificate issuer is guaranteed to uniquely identify a certificate (but not its owner — the owner ought to regularly change their keys, and get new certificates from the issuer).

So, if you run your own CA and allow only certificates from this CA to be accepted by the server, the serial number is the most reliable (albeit not very mnemonic) means to identify a user.

`ssl_client_dn()` returns text

Returns the full subject of the current client certificate, converting character data into the current database encoding. It is assumed that if you use non-ASCII characters in the certificate names, your database is able to represent these characters, too. If your database uses the SQL_ASCII encoding, non-ASCII characters in the name will be represented as UTF-8 sequences.

The result looks like `/CN=Somebody /C=Some country/O=Some organization`.

`ssl_issuer_dn()` returns text

Returns the full issuer name of the current client certificate, converting character data into the current database encoding. Encoding conversions are handled the same as for `ssl_client_dn`.

The combination of the return value of this function with the certificate serial number uniquely identifies the certificate.

This function is really useful only if you have more than one trusted CA certificate in your server's certificate authority file, or if this CA has issued some intermediate certificate authority certificates.

`ssl_client_dn_field(fieldname text)` returns text

This function returns the value of the specified field in the certificate subject, or NULL if the field is not present. Field names are string constants that are converted into ASN1 object identifiers using the OpenSSL object database. The following values are acceptable:

```
commonName (alias CN)
surname (alias SN)
name
givenName (alias GN)
countryName (alias C)
localityName (alias L)
stateOrProvinceName (alias ST)
organizationName (alias O)
organizationalUnitName (alias OU)
title
description
initials
postalCode
streetAddress
generationQualifier
description
dnQualifier
x500UniqueIdentifier
pseudonym
role
emailAddress
```

All of these fields are optional, except `commonName`. It depends entirely on your CA's policy which of them would be included and which wouldn't. The meaning of these fields, however, is strictly defined by the X.500 and X.509 standards, so you cannot just assign arbitrary meaning to them.

`ssl_issuer_field(fieldname text)` returns text

Same as `ssl_client_dn_field`, but for the certificate issuer rather than the certificate subject.

`ssl_extension_info()` returns setof record

Provide information about extensions of client certificate: extension name, extension value, and if it is a critical extension.

F.64. tablefunc

The `tablefunc` module includes various functions that return tables (that is, multiple rows). These functions are useful both in their own right and as examples of how to write C functions that return multiple rows.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.64.1. Functions Provided

[Table F.119](#) summarizes the functions provided by the `tablefunc` module.

Table F.119. tablefunc Functions

Function	Description
<code>normal_rand (numvals integer, mean float8, stddev float8) → setof float8</code>	Produces a set of normally distributed random values.
<code>crosstab (sql text) → setof record</code>	Produces a “pivot table” containing row names plus <i>N</i> value columns, where <i>N</i> is determined by the row type specified in the calling query.
<code>crosstabN (sql text) → setof table_crosstab_ N</code>	Produces a “pivot table” containing row names plus <i>N</i> value columns. <code>crosstab2</code> , <code>crosstab3</code> , and <code>crosstab4</code> are predefined, but you can create additional <code>crosstabN</code> functions as described below.
<code>crosstab (source_sql text, category_sql text) → setof record</code>	Produces a “pivot table” with the value columns specified by a second query.
<code>crosstab (sql text, N integer) → setof record</code>	Obsolete version of <code>crosstab(text)</code> . The parameter <i>N</i> is now ignored, since the number of value columns is always determined by the calling query.
<code>connectby (relname text, keyid_fld text, parent_keyid_fld text [, orderby_fld text], start_with text, max_depth integer [, branch_delim text]) → setof record</code>	Produces a representation of a hierarchical tree structure.

F.64.1.1. normal_rand

`normal_rand(int numvals, float8 mean, float8 stddev)` returns `setof float8`

`normal_rand` produces a set of normally distributed random values (Gaussian distribution).

numvals is the number of values to be returned from the function. *mean* is the mean of the normal distribution of values and *stddev* is the standard deviation of the normal distribution of values.

For example, this call requests 1000 values with a mean of 5 and a standard deviation of 3:

```
test=# SELECT * FROM normal_rand(1000, 5, 3);
      normal_rand
```

```
-----
```

```
1.56556322244898
9.10040991424657
5.36957140345079
-0.369151492880995
0.283600703686639
.
.
.
4.82992125404908
9.71308014517282
2.49639286969028
(1000 rows)
```

F.64.1.2. `crosstab(text)`

```
crosstab(text sql)
crosstab(text sql, int N)
```

The `crosstab` function is used to produce “pivot” displays, wherein data is listed across the page rather than down. For example, we might have data like

```
row1    val11
row1    val12
row1    val13
...
row2    val21
row2    val22
row2    val23
...
```

which we wish to display like

```
row1    val11    val12    val13    ...
row2    val21    val22    val23    ...
...
```

The `crosstab` function takes a text parameter that is a SQL query producing raw data formatted in the first way, and produces a table formatted in the second way.

The `sql` parameter is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. `N` is an obsolete parameter, ignored if supplied (formerly this had to match the number of output value columns, but now that is determined by the calling query).

For example, the provided query might produce a set something like:

row_name	cat	value
row1	cat1	val1
row1	cat2	val2
row1	cat3	val3
row1	cat4	val4
row2	cat1	val5
row2	cat2	val6
row2	cat3	val7
row2	cat4	val8

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...') AS ct(row_name text, category_1 text, category_2 text);
```

This example produces a set something like:

```

      <== value  columns  ==>
row_name  category_1  category_2
-----+-----+-----
row1      val1       val2
row2      val5       val6

```

The `FROM` clause must define the output as one `row_name` column (of the same data type as the first result column of the SQL query) followed by `N value` columns (all of the same data type as the third result column of the SQL query). You can set up as many output value columns as you wish. The names of the output columns are up to you.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. It fills the output `value` columns, left to right, with the `value` fields from these rows. If there are fewer rows in a group than there are output `value` columns, the extra output columns are filled with nulls; if there are more rows, the extra input rows are skipped.

In practice the SQL query should always specify `ORDER BY 1,2` to ensure that the input rows are properly ordered, that is, values with the same `row_name` are brought together and correctly ordered within the row. Notice that `crosstab` itself does not pay any attention to the second column of the query result; it's just there to be ordered by, to control the order in which the third-column values appear across the page.

Here is a complete example:

```

CREATE TABLE ct(id SERIAL, rowid TEXT, attribute TEXT, value TEXT);
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att1','val1');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att2','val2');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att3','val3');
INSERT INTO ct(rowid, attribute, value) VALUES('test1','att4','val4');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att1','val5');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att2','val6');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att3','val7');
INSERT INTO ct(rowid, attribute, value) VALUES('test2','att4','val8');

SELECT *
FROM crosstab(
  'select rowid, attribute, value
   from ct
   where attribute = ''att2'' or attribute = ''att3''
   order by 1,2')
AS ct(row_name text, category_1 text, category_2 text, category_3 text);

 row_name | category_1 | category_2 | category_3
-----+-----+-----+-----
test1    | val2       | val3       |
test2    | val6       | val7       |
(2 rows)

```

You can avoid always having to write out a `FROM` clause to define the output columns, by setting up a custom `crosstab` function that has the desired output row type wired into its definition. This is described in the next section. Another possibility is to embed the required `FROM` clause in a view definition.

Note

See also the `\crosstabview` command in `psql`, which provides functionality similar to `crosstab()`.

F.64.1.3. `crosstabN(text)`

```
crosstabN(text sql)
```

The `crosstabN` functions are examples of how to set up custom wrappers for the general `crosstab` function, so that you need not write out column names and types in the calling `SELECT` query. The `tablefunc` module includes `crosstab2`, `crosstab3`, and `crosstab4`, whose output row types are defined as

```
CREATE TYPE tablefunc_crosstab_N AS (  
    row_name TEXT,  
    category_1 TEXT,  
    category_2 TEXT,  
    .  
    .  
    .  
    category_N TEXT  
);
```

Thus, these functions can be used directly when the input query produces `row_name` and `value` columns of type `text`, and you want 2, 3, or 4 output values columns. In all other ways they behave exactly as described above for the general `crosstab` function.

For instance, the example given in the previous section would also work as

```
SELECT *  
FROM crosstab3(  
    'select rowid, attribute, value  
    from ct  
    where attribute = 'att2' or attribute = 'att3'  
    order by 1,2');
```

These functions are provided mostly for illustration purposes. You can create your own return types and functions based on the underlying `crosstab()` function. There are two ways to do it:

- Create a composite type describing the desired output columns, similar to the examples in `contrib/tablefunc/tablefunc--1.0.sql`. Then define a unique function name accepting one `text` parameter and returning `setof your_type_name`, but linking to the same underlying `crosstab C` function. For example, if your source data produces row names that are `text`, and values that are `float8`, and you want 5 value columns:

```
CREATE TYPE my_crosstab_float8_5_cols AS (  
    my_row_name text,  
    my_category_1 float8,  
    my_category_2 float8,  
    my_category_3 float8,  
    my_category_4 float8,  
    my_category_5 float8  
);  
  
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(text)  
    RETURNS setof my_crosstab_float8_5_cols  
    AS '$libdir/tablefunc', 'crosstab' LANGUAGE C STABLE STRICT;
```

- Use `OUT` parameters to define the return type implicitly. The same example could also be done this way:

```
CREATE OR REPLACE FUNCTION crosstab_float8_5_cols(  
    IN text,  
    OUT my_row_name text,  
    OUT my_category_1 float8,  
    OUT my_category_2 float8,  
    OUT my_category_3 float8,  
    OUT my_category_4 float8,  
    OUT my_category_5 float8)  
    RETURNS setof record
```

```
AS '$libdir/tablefunc','crosstab' LANGUAGE C STABLE STRICT;
```

F.64.1.4. `crosstab(text, text)`

```
crosstab(text source_sql, text category_sql)
```

The main limitation of the single-parameter form of `crosstab` is that it treats all values in a group alike, inserting each value into the first available column. If you want the value columns to correspond to specific categories of data, and some groups might not have data for some of the categories, that doesn't work well. The two-parameter form of `crosstab` handles this case by providing an explicit list of the categories corresponding to the output columns.

`source_sql` is a SQL statement that produces the source set of data. This statement must return one `row_name` column, one `category` column, and one `value` column. It may also have one or more “extra” columns. The `row_name` column must be first. The `category` and `value` columns must be the last two columns, in that order. Any columns between `row_name` and `category` are treated as “extra”. The “extra” columns are expected to be the same for all rows with the same `row_name` value.

For example, `source_sql` might produce a set something like:

```
SELECT row_name, extra_col, cat, value FROM foo ORDER BY 1;
```

row_name	extra_col	cat	value
row1	extra1	cat1	val1
row1	extra1	cat2	val2
row1	extra1	cat4	val4
row2	extra2	cat1	val5
row2	extra2	cat2	val6
row2	extra2	cat3	val7
row2	extra2	cat4	val8

`category_sql` is a SQL statement that produces the set of categories. This statement must return only one column. It must produce at least one row, or an error will be generated. Also, it must not produce duplicate values, or an error will be generated. `category_sql` might be something like:

```
SELECT DISTINCT cat FROM foo ORDER BY 1;
cat
-----
cat1
cat2
cat3
cat4
```

The `crosstab` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```
SELECT * FROM crosstab('...', '...')
AS ct(row_name text, extra text, cat1 text, cat2 text, cat3 text, cat4 text);
```

This will produce a result something like:

		<== value columns ==>			
row_name	extra	cat1	cat2	cat3	cat4
row1	extra1	val1	val2		val4
row2	extra2	val5	val6	val7	val8

The `FROM` clause must define the proper number of output columns of the proper data types. If there are N columns in the `source_sql` query's result, the first $N-2$ of them must match up with the first $N-2$ output columns. The remaining output columns must have the type of the last column of the `source_sql` query's result, and there must be exactly as many of them as there are rows in the `category_sql` query's result.

The `crosstab` function produces one output row for each consecutive group of input rows with the same `row_name` value. The output `row_name` column, plus any “extra” columns, are copied from the first row of the group. The output `value` columns are filled with the `value` fields from rows having matching category values. If a row's `category` does not match any output of the `category_sql` query, its `value` is ignored. Output columns whose matching category is not present in any input row of the group are filled with nulls.

In practice the `source_sql` query should always specify `ORDER BY 1` to ensure that values with the same `row_name` are brought together. However, ordering of the categories within a group is not important. Also, it is essential to be sure that the order of the `category_sql` query's output matches the specified output column order.

Here are two complete examples:

```
create table sales(year int, month int, qty int);
insert into sales values(2007, 1, 1000);
insert into sales values(2007, 2, 1500);
insert into sales values(2007, 7, 500);
insert into sales values(2007, 11, 1500);
insert into sales values(2007, 12, 2000);
insert into sales values(2008, 1, 1000);
```

```
select * from crosstab(
  'select year, month, qty from sales order by 1',
  'select m from generate_series(1,12) m'
) as (
  year int,
  "Jan" int,
  "Feb" int,
  "Mar" int,
  "Apr" int,
  "May" int,
  "Jun" int,
  "Jul" int,
  "Aug" int,
  "Sep" int,
  "Oct" int,
  "Nov" int,
  "Dec" int
);
```

year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2007	1000	1500					500				1500	2000
2008	1000											

(2 rows)

```
CREATE TABLE cth(rowid text, rowdt timestamp, attribute text, val text);
INSERT INTO cth VALUES('test1','01 March 2003','temperature','42');
INSERT INTO cth VALUES('test1','01 March 2003','test_result','PASS');
INSERT INTO cth VALUES('test1','01 March 2003','volts','2.6987');
INSERT INTO cth VALUES('test2','02 March 2003','temperature','53');
INSERT INTO cth VALUES('test2','02 March 2003','test_result','FAIL');
INSERT INTO cth VALUES('test2','02 March 2003','test_startdate','01 March 2003');
INSERT INTO cth VALUES('test2','02 March 2003','volts','3.1234');
```

```
SELECT * FROM crosstab
(
  'SELECT rowid, rowdt, attribute, val FROM cth ORDER BY 1',
  'SELECT DISTINCT attribute FROM cth ORDER BY 1'
```

```

)
AS
(
    rowid text,
    rowdt timestamp,
    temperature int4,
    test_result text,
    test_startdate timestamp,
    volts float8
);
rowid |          rowdt          | temperature | test_result |          test_startdate
| volts
-----+-----+-----+-----+-----
+-----+-----+-----+-----+-----
test1 | Sat Mar 01 00:00:00 2003 |          42 | PASS        |
| 2.6987
test2 | Sun Mar 02 00:00:00 2003 |          53 | FAIL        | Sat Mar 01 00:00:00
2003 | 3.1234
(2 rows)

```

You can create predefined functions to avoid having to write out the result column names and types in each query. See the examples in the previous section. The underlying C function for this form of `crosstab` is named `crosstab_hash`.

F.64.1.5. connectby

```

connectby(text relname, text keyid_fld, text parent_keyid_fld
        [, text orderby_fld ], text start_with, int max_depth
        [, text branch_delim ])

```

The `connectby` function produces a display of hierarchical data that is stored in a table. The table must have a key field that uniquely identifies rows, and a parent-key field that references the parent (if any) of each row. `connectby` can display the sub-tree descending from any row.

Table F.120 explains the parameters.

Table F.120. connectby Parameters

Parameter	Description
<i>relname</i>	Name of the source relation
<i>keyid_fld</i>	Name of the key field
<i>parent_keyid_fld</i>	Name of the parent-key field
<i>orderby_fld</i>	Name of the field to order siblings by (optional)
<i>start_with</i>	Key value of the row to start at
<i>max_depth</i>	Maximum depth to descend to, or zero for unlimited depth
<i>branch_delim</i>	String to separate keys with in branch output (optional)

The key and parent-key fields can be any data type, but they must be the same type. Note that the *start_with* value must be entered as a text string, regardless of the type of the key field.

The `connectby` function is declared to return `setof record`, so the actual names and types of the output columns must be defined in the `FROM` clause of the calling `SELECT` statement, for example:

```

SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
    '~')

```

```
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
```

The first two output columns are used for the current row's key and its parent row's key; they must match the type of the table's key field. The third output column is the depth in the tree and must be of type `integer`. If a `branch_delim` parameter was given, the next output column is the branch display and must be of type `text`. Finally, if an `orderby_fld` parameter was given, the last output column is a serial number, and must be of type `integer`.

The “branch” output column shows the path of keys taken to reach the current row. The keys are separated by the specified `branch_delim` string. If no branch display is wanted, omit both the `branch_delim` parameter and the branch column in the output column list.

If the ordering of siblings of the same parent is important, include the `orderby_fld` parameter to specify which field to order siblings by. This field can be of any sortable data type. The output column list must include a final integer serial-number column, if and only if `orderby_fld` is specified.

The parameters representing table and field names are copied as-is into the SQL queries that `connectby` generates internally. Therefore, include double quotes if the names are mixed-case or contain special characters. You may also need to schema-qualify the table name.

In large tables, performance will be poor unless there is an index on the parent-key field.

It is important that the `branch_delim` string not appear in any key values, else `connectby` may incorrectly report an infinite-recursion error. Note that if `branch_delim` is not provided, a default value of `~` is used for recursion detection purposes.

Here is an example:

```
CREATE TABLE connectby_tree(keyid text, parent_keyid text, pos int);
```

```
INSERT INTO connectby_tree VALUES('row1',NULL, 0);
INSERT INTO connectby_tree VALUES('row2','row1', 0);
INSERT INTO connectby_tree VALUES('row3','row1', 0);
INSERT INTO connectby_tree VALUES('row4','row2', 1);
INSERT INTO connectby_tree VALUES('row5','row2', 0);
INSERT INTO connectby_tree VALUES('row6','row4', 0);
INSERT INTO connectby_tree VALUES('row7','row3', 0);
INSERT INTO connectby_tree VALUES('row8','row6', 0);
INSERT INTO connectby_tree VALUES('row9','row5', 0);
```

```
-- with branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0, '~')
AS t(keyid text, parent_keyid text, level int, branch text);
```

keyid	parent_keyid	level	branch
row2		0	row2
row4	row2	1	row2~row4
row6	row4	2	row2~row4~row6
row8	row6	3	row2~row4~row6~row8
row5	row2	1	row2~row5
row9	row5	2	row2~row5~row9

(6 rows)

```
-- without branch, without orderby_fld (order of results is not guaranteed)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'row2', 0)
AS t(keyid text, parent_keyid text, level int);
```

keyid	parent_keyid	level
row2		0
row4	row2	1

```
row6 | row4      |      2
row8 | row6      |      3
row5 | row2      |      1
row9 | row5      |      2
(6 rows)
```

```
-- with branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0,
 '~')
AS t(keyid text, parent_keyid text, level int, branch text, pos int);
keyid | parent_keyid | level |      branch      | pos
-----+-----+-----+-----+-----
row2  |              |      0 | row2              | 1
row5  | row2         |      1 | row2~row5         | 2
row9  | row5         |      2 | row2~row5~row9    | 3
row4  | row2         |      1 | row2~row4         | 4
row6  | row4         |      2 | row2~row4~row6    | 5
row8  | row6         |      3 | row2~row4~row6~row8 | 6
(6 rows)
```

```
-- without branch, with orderby_fld (notice that row5 comes before row4)
SELECT * FROM connectby('connectby_tree', 'keyid', 'parent_keyid', 'pos', 'row2', 0)
AS t(keyid text, parent_keyid text, level int, pos int);
keyid | parent_keyid | level | pos
-----+-----+-----+-----
row2  |              |      0 | 1
row5  | row2         |      1 | 2
row9  | row5         |      2 | 3
row4  | row2         |      1 | 4
row6  | row4         |      2 | 5
row8  | row6         |      3 | 6
(6 rows)
```

F.64.2. Author

Joe Conway

F.65. tcn

The `tcn` module provides a trigger function that notifies listeners of changes to any table on which it is attached. It must be used as an `AFTER trigger FOR EACH ROW`.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

Only one parameter may be supplied to the function in a `CREATE TRIGGER` statement, and that is optional. If supplied it will be used for the channel name for the notifications. If omitted `tcn` will be used for the channel name.

The payload of the notifications consists of the table name, a letter to indicate which type of operation was performed, and column name/value pairs for primary key columns. Each part is separated from the next by a comma. For ease of parsing using regular expressions, table and column names are always wrapped in double quotes, and data values are always wrapped in single quotes. Embedded quotes are doubled.

A brief example of using the extension follows.

```
test=# create table tcndata
test=#   (
```

```

test(#      a int not null,
test(#      b date not null,
test(#      c text,
test(#      primary key (a, b)
test(#      );
CREATE TABLE
test=# create trigger tcndata_tcn_trigger
test=#      after insert or update or delete on tcndata
test=#      for each row execute function triggered_change_notification();
CREATE TRIGGER
test=# listen tcn;
LISTEN
test=# insert into tcndata values (1, date '2012-12-22', 'one'),
test=#                                     (1, date '2012-12-23', 'another'),
test=#                                     (2, date '2012-12-23', 'two');
INSERT 0 3
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",I,"a"='2',"b"='2012-12-23'"
received from server process with PID 22770.
test=# update tcndata set c = 'uno' where a = 1;
UPDATE 2
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.
Asynchronous notification "tcn" with payload ""tcndata",U,"a"='1',"b"='2012-12-23'"
received from server process with PID 22770.
test=# delete from tcndata where a = 1 and b = date '2012-12-22';
DELETE 1
Asynchronous notification "tcn" with payload ""tcndata",D,"a"='1',"b"='2012-12-22'"
received from server process with PID 22770.

```

F.66. test_decoding

`test_decoding` is an example of a logical decoding output plugin. It doesn't do anything especially useful, but can serve as a starting point for developing your own output plugin.

`test_decoding` receives WAL through the logical decoding mechanism and decodes it into text representations of the operations performed.

Typical output from this plugin, used over the SQL logical decoding interface, might be:

```

postgres=# SELECT * FROM pg_logical_slot_get_changes('test_slot', NULL, NULL, 'include-
xids', '0');
 location | xid | data
-----+-----+-----
 0/16D30F8 | 691 | BEGIN
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:2 data[text]:'arg'
 0/16D32A0 | 691 | table public.data: INSERT: id[int4]:3 data[text]:'demo'
 0/16D32A0 | 691 | COMMIT
 0/16D32D8 | 692 | BEGIN
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:2
 0/16D3398 | 692 | table public.data: DELETE: id[int4]:3
 0/16D3398 | 692 | COMMIT
(8 rows)

```

F.67. tsm_system_rows

The `tsm_system_rows` module provides the table sampling method `SYSTEM_ROWS`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single integer argument that is the maximum number of rows to read. The resulting sample will always contain exactly that many rows, unless the table does not contain enough rows, in which case the whole table is selected.

Like the built-in `SYSTEM` sampling method, `SYSTEM_ROWS` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are requested.

`SYSTEM_ROWS` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.67.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_ROWS`. First install the extension:

```
CREATE EXTENSION tsm_system_rows;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_ROWS(100);
```

This command will return a sample of 100 rows from the table `my_table` (unless the table does not have 100 visible rows, in which case all its rows are returned).

F.68. `tsm_system_time`

The `tsm_system_time` module provides the table sampling method `SYSTEM_TIME`, which can be used in the `TABLESAMPLE` clause of a `SELECT` command.

This table sampling method accepts a single floating-point argument that is the maximum number of milliseconds to spend reading the table. This gives you direct control over how long the query takes, at the price that the size of the sample becomes hard to predict. The resulting sample will contain as many rows as could be read in the specified time, unless the whole table has been read first.

Like the built-in `SYSTEM` sampling method, `SYSTEM_TIME` performs block-level sampling, so that the sample is not completely random but may be subject to clustering effects, especially if only a small number of rows are selected.

`SYSTEM_TIME` does not support the `REPEATABLE` clause.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.68.1. Examples

Here is an example of selecting a sample of a table with `SYSTEM_TIME`. First install the extension:

```
CREATE EXTENSION tsm_system_time;
```

Then you can use it in a `SELECT` command, for instance:

```
SELECT * FROM my_table TABLESAMPLE SYSTEM_TIME(1000);
```

This command will return as large a sample of `my_table` as it can read in 1 second (1000 milliseconds). Of course, if the whole table can be read in under 1 second, all its rows will be returned.

F.69. `unaccent`

`unaccent` is a text search dictionary that removes accents (diacritic signs) from lexemes. It's a filtering dictionary, which means its output is always passed to the next dictionary (if any), unlike the normal behavior of dictionaries. This allows accent-insensitive processing for full text search.

The current implementation of `unaccent` cannot be used as a normalizing dictionary for the `thesaurus` dictionary.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.69.1. Configuration

An `unaccent` dictionary accepts the following options:

- `RULES` is the base name of the file containing the list of translation rules. This file must be stored in `$$SHAREDIR/tsearch_data/` (where `$$SHAREDIR` means the Postgres Pro installation's shared-data directory). Its name must end in `.rules` (which is not to be included in the `RULES` parameter).

The rules file has the following format:

- Each line represents one translation rule, consisting of a character with accent followed by a character without accent. The first is translated into the second. For example,

À	A
Á	A
Â	A
Ã	A
Ä	A
Å	A
Æ	AE

The two characters must be separated by whitespace, and any leading or trailing whitespace on a line is ignored.

- Alternatively, if only one character is given on a line, instances of that character are deleted; this is useful in languages where accents are represented by separate characters.
- Actually, each “character” can be any string not containing whitespace, so `unaccent` dictionaries could be used for other sorts of substring substitutions besides diacritic removal.
- As with other Postgres Pro text search configuration files, the rules file must be stored in UTF-8 encoding. The data is automatically translated into the current database's encoding when loaded. Any lines containing untranslatable characters are silently ignored, so that rules files can contain rules that are not applicable in the current encoding.

A more complete example, which is directly useful for most European languages, can be found in `unaccent.rules`, which is installed in `$$SHAREDIR/tsearch_data/` when the `unaccent` module is installed. This rules file translates characters with accents to the same characters without accents, and it also expands ligatures into the equivalent series of simple characters (for example, `Æ` to `AE`).

F.69.2. Usage

Installing the `unaccent` extension creates a text search template `unaccent` and a dictionary `unaccent` based on it. The `unaccent` dictionary has the default parameter setting `RULES='unaccent'`, which makes it immediately usable with the standard `unaccent.rules` file. If you wish, you can alter the parameter, for example

```
mydb=# ALTER TEXT SEARCH DICTIONARY unaccent (RULES='my_rules');
```

or create new dictionaries based on the template.

To test the dictionary, you can try:

```
mydb=# select ts_lexize('unaccent','Hôtel');
```

```
ts_lexize
-----
{Hotel}
(1 row)
```

Here is an example showing how to insert the `unaccent` dictionary into a text search configuration:

```
mydb=# CREATE TEXT SEARCH CONFIGURATION fr ( COPY = french );
mydb=# ALTER TEXT SEARCH CONFIGURATION fr
        ALTER MAPPING FOR hword, hword_part, word
        WITH unaccent, french_stem;
mydb=# select to_tsvector('fr','Hôtels de la Mer');
        to_tsvector
-----
 'hotel':1 'mer':4
(1 row)

mydb=# select to_tsvector('fr','Hôtel de la Mer') @@ to_tsquery('fr','Hotels');
        ?column?
-----
 t
(1 row)

mydb=# select ts_headline('fr','Hôtel de la Mer',to_tsquery('fr','Hotels'));
        ts_headline
-----
 <b>Hôtel</b> de la Mer
(1 row)
```

F.69.3. Functions

The `unaccent()` function removes accents (diacritic signs) from a given string. Basically, it's a wrapper around `unaccent-type` dictionaries, but it can be used outside normal text search contexts.

`unaccent([dictionary regdictionary, ] string text)` returns *text*

If the *dictionary* argument is omitted, the text search dictionary named `unaccent` and appearing in the same schema as the `unaccent()` function itself is used.

For example:

```
SELECT unaccent('unaccent', 'Hôtel');
SELECT unaccent('Hôtel');
```

F.70. uuid-oss

The `uuid-oss` module provides functions to generate universally unique identifiers (UUIDs) using one of several standard algorithms. There are also functions to produce certain special UUID constants. This module is only necessary for special requirements beyond what is available in core PostgreSQL. See [Section 9.14](#) for built-in ways to generate UUIDs.

This module is considered “trusted”, that is, it can be installed by non-superusers who have `CREATE` privilege on the current database.

F.70.1. uuid-oss Functions

[Table F.121](#) shows the functions available to generate UUIDs. The relevant standards ITU-T Rec. X.667, ISO/IEC 9834-8:2005, and RFC 4122 specify four algorithms for generating UUIDs, identified by the version numbers 1, 3, 4, and 5. (There is no version 2 algorithm.) Each of these algorithms could be suitable for a different set of applications.

Table F.121. Functions for UUID Generation

Function	Description
<code>uuid_generate_v1 () → uuid</code>	Generates a version 1 UUID. This involves the MAC address of the computer and a time stamp. Note that UUIDs of this kind reveal the identity of the computer that created the identifier and the time at which it did so, which might make it unsuitable for certain security-sensitive applications.
<code>uuid_generate_v1mc () → uuid</code>	Generates a version 1 UUID, but uses a random multicast MAC address instead of the real MAC address of the computer.
<code>uuid_generate_v3 (namespace uuid, name text) → uuid</code>	Generates a version 3 UUID in the given namespace using the specified input name. The namespace should be one of the special constants produced by the <code>uuid_ns_*</code> () functions shown in Table F.122. (It could be any UUID in theory.) The name is an identifier in the selected namespace. For example: <pre>SELECT uuid_generate_v3(uuid_ns_url(), 'http://www.postgresql.org');</pre> The name parameter will be MD5-hashed, so the cleartext cannot be derived from the generated UUID. The generation of UUIDs by this method has no random or environment-dependent element and is therefore reproducible.
<code>uuid_generate_v4 () → uuid</code>	Generates a version 4 UUID, which is derived entirely from random numbers.
<code>uuid_generate_v5 (namespace uuid, name text) → uuid</code>	Generates a version 5 UUID, which works like a version 3 UUID except that SHA-1 is used as a hashing method. Version 5 should be preferred over version 3 because SHA-1 is thought to be more secure than MD5.

Table F.122. Functions Returning UUID Constants

Function	Description
<code>uuid_nil () → uuid</code>	Returns a “nil” UUID constant, which does not occur as a real UUID.
<code>uuid_ns_dns () → uuid</code>	Returns a constant designating the DNS namespace for UUIDs.
<code>uuid_ns_url () → uuid</code>	Returns a constant designating the URL namespace for UUIDs.
<code>uuid_ns_oid () → uuid</code>	Returns a constant designating the ISO object identifier (OID) namespace for UUIDs. (This pertains to ASN.1 OIDs, which are unrelated to the OIDs used in Postgres Pro.)
<code>uuid_ns_x500 () → uuid</code>	Returns a constant designating the X.500 distinguished name (DN) namespace for UUIDs.

F.70.2. Building `uuid-oss`

Historically this module depended on the OSSP UUID library, which accounts for the module's name. While the OSSP UUID library can still be found at <http://www.ossdp.org/pkg/lib/uuid/>, it is not well maintained, and is becoming increasingly difficult to port to newer platforms. `uuid-oss` can now be built without the OSSP library on some platforms. On FreeBSD and some other BSD-derived platforms, suit-

able UUID creation functions are included in the core `libc` library. On Linux, macOS, and some other platforms, suitable functions are provided in the `libuuid` library, which originally came from the `e2fsprogs` project (though on modern Linux it is considered part of `util-linux-ng`). When invoking `configure`, specify `--with-uuid=bsd` to use the BSD functions, or `--with-uuid=e2fs` to use `e2fsprogs`' `libuuid`, or `--with-uuid=ossf` to use the OSSP UUID library. More than one of these libraries might be available on a particular machine, so `configure` does not automatically choose one.

Peter Eisentraut <peter_e@gmx.net>

F.71. vops

The `vops` module is an experimental Postgres Pro Enterprise extension that provides support for vector operations, which allows to speed up OLAP queries with filtering and aggregation more than 10 times. Performance improvements are achieved by implementing a vertical data model that allows storing data in *tiles*, or groups of column values. Such a storage format is also called *Parquet* in some analytical databases. Reducing the overhead of unpacking tuples, vertical data model allows to speed up query execution without any radical changes in Postgres Pro planner and executor.

`vops` provides its own set of vector functions that can be used inside predicates and aggregate expressions. To avoid learning new syntax, you can use [postgres_fdw](#) as an abstraction layer and run regular SQL queries on vectorized data. For query types other than filtering and aggregation, `vops` can also use `postgres_fdw` to present vectorized data as a regular table with scalar column types and process this data as regular tuples. For ease of use, `vops` also provides an automated way of generating and accessing vectorized data, as explained in [Section F.71.5.5](#).

F.71.1. Limitations

- Tile-based tables only allow `INSERT` and `APPEND` operations. Once imported, vectorized data cannot be updated.
- Vector operations are only available for filtering and aggregation. Other query types are supported via `postgres_fdw`.
- Aggregate expressions must be of the same type.
- `JOIN` operations are not supported for vector types. You have to use `postgres_fdw` to transform vectorized data back to regular tuples to run such queries.
- Since `postgres_fdw` does not support parallel query execution, you can only run parallel queries when using vector operators directly.

F.71.2. Installation and Setup

The `vops` extension is included into Postgres Pro Enterprise. Once you have Postgres Pro Enterprise installed, complete the following steps to enable `vops`:

1. Add `vops` to the [shared_preload_libraries](#) parameter in the `postgresql.conf` file:

```
shared_preload_libraries = 'vops'
```

Note

If the extension library is not added to the `shared_preload_libraries` list, it will be loaded on demand after the first function invocation of this extension. In this case, the first time you execute a vectorized query, it will not be processed correctly and can return a wrong result.

2. Restart the Postgres Pro Enterprise instance for the changes to take effect.

3. Create `vops` extension:

```
CREATE EXTENSION vops;
```

Once `vops` is enabled, you can create vectorized tables and query data using vector operations in your database.

If you would like to use regular SQL syntax for vector types, you must also enable [postgres_fdw](#).

F.71.3. Motivation

For OLTP workloads, Postgres Pro looks very competitive as compared to other mainstream databases. However, for OLAP queries, which require processing larger volumes of data, analytics-oriented database management systems can provide a much better speed. There are several main factors that limit Postgres Pro performance:

- **Tuple unpacking overhead.** To access column values, Postgres Pro needs to unpack the tuple. As tables can have columns of variable-length data types, to extract the N-th column, the preceding N-1 columns need to be unpacked. Thus, deforming a tuple is quite an expensive operation, especially for tables with a large number of attributes. Besides, values can be compressed or stored in another page (TOAST). In queries like Query 6 of the [TPC-H benchmark](#), deforming tuples takes about 40% of the total query execution time.
- **Interpretation overhead.** Postgres Pro planner and optimizer build a tree representing the query execution plan. Query executor recursively calls functions that evaluate the nodes of this tree. Some nodes may also contain switches used to select the requested action. Thus, query plan is interpreted by Postgres Pro query executor rather than directly executed. The interpreter is usually about 10 times slower than the native code. If you eliminate interpretation overhead, you can increase query speed several times, especially for queries with complex predicates that have high evaluation costs.
- **Abstraction penalty.** Support for abstract (user-defined) types and operations is one of the key features of Postgres Pro. However, the price of such flexibility is that each operation requires a separate function call. Instead of adding two integers directly, Postgres Pro executor invokes a function that performs addition. In this case, function call overhead is much higher than the cost the operation itself. Function call overhead is also increased because Postgres Pro requires passing parameter values through memory.
- **Pull model overhead.** In Postgres Pro, operators pull the operand values. This approach simplifies the implementation of operators and the executor, but has a negative impact on performance. In this model, leaf nodes that fetch a tuple from the heap or index pages have to do a lot of extra work while saving and restoring their context.
- **MVCC overhead.** Postgres Pro provides multi-version concurrency control, which allows multiple transactions to work with the same record in parallel without blocking each other. It is good for frequently updated data (OLTP), but for read-only or append-only data in OLAP scenarios it only adds both space overhead (about 20 extra bytes per tuple) and CPU overhead (checking visibility of each tuple).

Vector operations can address most of these issues without radical changes in the Postgres Pro executor, as explained in [Section F.71.4](#).

F.71.4. Architecture

The `vops` extension implements a *vertical data model* for Postgres Pro. In this model, vertical columns are used as a data storing unit, with the values of the corresponding table attribute forming a vector.

The vertical data model used by `vops` has the following advantages:

- **Reduces the size of fetched data:** only the columns used in the query need to be fetched.
- **Achieves higher compression rates:** storing all values of the same attribute together makes it possible to compress them much better and faster. For example, you can use delta encoding.
- **Minimizes interpretation overhead:** a set of values can be processed by a single operation instead of running separate operations for each value.

- Uses CPU vector instructions (SIMD) to process data.

A traditional Postgres Pro query executor deals with a single row of data at each moment of time. For example, to evaluate an expression $(x+y)$, it first fetches the value of x , then fetches the value of y , performs the addition, and returns the result value to the upper node. In contrast, a vectorized executor can process multiple values within a single operation. In this case, x and y represent vectors of values instead of single scalars. The returned result is also a vector. In vector execution model, interpretation and function call overhead is divided by the vector size. The price of performing a function call is the same, but as the function processes N values instead of a single one, this overhead becomes less critical. The larger the vector, the smaller the per-row overhead.

However, performing an operation on the whole column may also turn out to be ineffective. Working with large vectors prevents efficient utilization of CPU cache levels. If the table is very large, the vector may not fit in memory at all. To avoid these issues, `vops` splits the columns into relatively small chunks, or *tiles*. The size of a tile is currently set to 64 elements. It allows to keep all operands of vector operations in cache, even for complex expressions.

The `vops` extension implements special vector types to be used instead of scalar types for table columns. The available types are listed in [Section F.71.6.1](#). To use `vops`, you have to create vectorized projections of original tables, with at least some attributes using these tile types, as explained in [Section F.71.5.1](#).

The original table can be treated as a write-optimized storage: if it has no indexes, Postgres Pro can provide a very fast insertion speed, comparable to raw disk write speed. Vectorized projection can be treated as a read-optimized storage, which is most efficient for running OLAP queries.

Once all the data is in the tile-based format, you can run vectorized queries on this data. `vops` provides a set of [vector operators](#) to work with vector types. Using these operators, you can write queries for filtering and aggregation, similar to SQL queries. For details, see [Section F.71.5.2](#).

For other query types, `vops` allows to work with vectorized data via `postgres_fdw`. You can add vectorized data to your database cluster as a foreign table and use regular SQL for running any types of queries on this data. Using the implicit type casts and post-parse `ANALYZE` hook, the `vops` extension either transforms the query to use vector operators for filtering and aggregation, or processes the data using scalar operators for other query types. For details, see [Section F.71.5.3](#).

F.71.5. Usage

F.71.5.1. Converting Data into Vectorized Format

To start using vector operations, you have to convert your data into a vectorized format, as explained below.

1. Create an empty vectorized table.

To use vector operations, you need to load data into a tile-based vectorized table, which can be treated as a *projection* of the original table. It can map all columns of the original table, or include some of the most frequently used columns only. To create a vectorized table, you can use the regular [CREATE TABLE](#) syntax, but at least some of the columns must be of [vector types](#).

For example, suppose you have the following table from the TPC-H benchmark:

```
CREATE TABLE lineitem(  
    l_orderkey integer,  
    l_partkey integer,  
    l_suppkey integer,  
    l_linenummer integer,  
    l_quantity double precision,  
    l_extendedprice double precision,  
    l_discount double precision,  
    l_tax double precision,  
    l_returnflag "char",
```

```
l_linestatus "char",
l_shipdate date,
l_commitdate date,
l_receiptdate date,
l_shipinstruct char(25),
l_shipmode char(10),
l_comment char(44));
```

To create a vectorized projection that includes only a subset of the original columns, you can run:

```
CREATE TABLE vops_lineitem(
  l_shipdate vops_date not null,
  l_quantity vops_float8 not null,
  l_extendedprice vops_float8 not null,
  l_discount vops_float8 not null,
  l_tax vops_float8 not null,
  l_returnflag vops_char not null,
  l_linestatus vops_char not null
);
```

Alternatively, you can keep the scalar type for some of the columns. In this case, you can sort the data by these columns when loading the data. For example, let's create another vectorized projection where `l_returnflag` and `l_linestatus` fields remain scalar:

```
CREATE TABLE vops_lineitem_projection(
  l_shipdate vops_date not null,
  l_quantity vops_float8 not null,
  l_extendedprice vops_float8 not null,
  l_discount vops_float8 not null,
  l_tax vops_float8 not null,
  l_returnflag "char" not null,
  l_linestatus "char" not null
);
```

In this table, `l_returnflag` and `l_linestatus` fields are scalar, while all the other fields are of the vector types that can be used in vector operations.

2. Load the data into the vectorized table.

- If the data to load is already stored in your database, use the [populate\(\)](#) function to preprocess the data and unite attribute values of several rows inside a single tile. This function loads the data from the original table into its vectorized projection, using vector types instead of scalar types, as specified in the created empty table.

For example:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=
  'lineitem'::regclass);
```

Once the table is populated, you can start running queries performing sequential scan.

Optionally, you can sort the data by one or more scalar columns when loading the data:

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=
  'lineitem'::regclass, sort := 'l_returnflag,l_linestatus');
```

If you sort the original table by the scalar columns that have a lot of duplicates, `vops` can effectively collapse them and store the corresponding attribute values in tiles, which can reduce the occupied space, speed up queries, and facilitate [index creation](#) on these scalar columns.

- If your data is not yet loaded into the database and you would like to avoid having two copies of the same dataset, you can import the data into a vectorized table directly from a CSV file using the [import\(\)](#) function, bypassing creation of a regular table. For example:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/
lineitem.csv', separator := '|');
```

For detailed description and syntax of the `populate()` and `import()` functions, see [Section F.71.6.4](#).

Once your data is in the tile-based format, you can run queries on this data using [vector operators](#), as described in [Section F.71.5.2](#). If you create a foreign vectorized table, you can also run regular SQL queries. See [Section F.71.5.3](#) for details.

F.71.5.2. Running Queries on Vectorized Data

`vops` implements its own vector functions and operators for working with vectorized data. See [Section F.71.6](#) for the full list of vector functions and operators and their usage specifics.

F.71.5.2.1. Aggregating Vectorized Data

OLAP queries often aggregate large volumes of data. To enable aggregate operations for vector types, `vops` implements the following aggregate functions for vectorized data: `count`, `min`, `max`, `avg`, `var_pop`, `var_sampl`, `variance`, `stddev_pop`, `stddev_samp`, `stddev`. Besides, `vops` provides the `wavg` aggregate function that calculates volume-weighted average price (VWAP).

The `vops` extension supports the following types of aggregates:

- grand aggregates calculated for the whole table
- aggregates for subsets of table rows defined by the `GROUP BY` clause

F.71.5.2.1.1. Calculating Grand Aggregates

To calculate grand aggregates, you can use the provided vector aggregate functions exactly like in regular SQL queries.

Examples:

To calculate volume-weighted average price, run the following query:

```
SELECT wavg(l_extendedprice, l_quantity) FROM vops_lineitem;
```

To calculate the company revenue for the year 1996 based on discounted prices of the shipped goods, run:

```
SELECT sum(l_extendedprice*l_discount) AS revenue
FROM vops_lineitem
WHERE filter(betwixt(l_shipdate, '1996-01-01', '1997-01-01')
& betwixt(l_discount, 0.08, 0.1)
& (l_quantity < 24));
```

F.71.5.2.1.2. Calculating Grouped Aggregates

To support grouped aggregates, `vops` provides `map()` and `reduce()` functions:

- The `map()` function collects aggregate states for all groups in a hash table. Its syntax is as follows:

```
map(group_by_expression,
    aggregate_list, expr {,
    expr })
```

- The `reduce()` function iterates through the hash table constructed by `map` and returns the set. The `reduce` function is needed because the result of aggregation in Postgres Pro cannot be a set.

Consider the following example:

```
SELECT reduce(map(l_returnflag||l_linestatus, 'sum,sum,sum,sum,avg,avg,avg',
    l_quantity,
    l_extendedprice,
    l_extendedprice*(1-l_discount),
```

```
l_extendedprice*(1-l_discount)*(1+l_tax),
l_quantity,
l_extendedprice,
l_discount))
FROM vops_lineitem
WHERE filter(l_shipdate <= '1998-12-01'::date);
```

The concatenation operator `||` performs grouping by two columns. The `vops` extension supports grouping only by an integer type. The `map` function accepts aggregation arguments as a variadic array, so all elements of this array should have the same type. For example, you cannot calculate aggregates for `vops_float4` and `vops_int8` columns in a single operation.

An aggregate string in `map` function should contain the list of aggregate functions to call, in a comma-separated format. Standard lowercase names should be used: `count`, `sum`, `agg`, `min`, `max`. Count is executed for the particular column: `count(x)`. There is no need to explicitly specify `count(*)` because the number of records in each group is returned by `reduce` function in any case.

`reduce` function returns set of the `vops_aggregate` type. It contains three components: the value of the `GROUP BY` expression, the number of records in the group, and an array of floats with aggregate values. The values of all aggregates, including `count` and `min/max`, are returned as floats.

Alternatively, you can partition the vectorized table by the `GROUP BY` fields to calculate grouped aggregates. In this case, grouping keys are stored as regular scalar values, while other fields are stored inside tiles. Now Postgres Pro executor will execute `vops` aggregates for each group:

```
SELECT
    l_returnflag,
    l_linestatus,
    sum(l_quantity) as sum_qty,
    sum(l_extendedprice) AS sum_base_price,
    sum(l_extendedprice*(1-l_discount)) AS sum_disc_price,
    sum(l_extendedprice*(1-l_discount)*(1+l_tax)) AS sum_charge,
    avg(l_quantity) AS avg_qty,
    avg(l_extendedprice) AS avg_price,
    avg(l_discount) AS avg_disc,
    count(*) AS count_order
FROM
    vops_lineitem_projection
WHERE
    filter(l_shipdate <= '1998-12-01'::date)
GROUP BY
    l_returnflag,
    l_linestatus
ORDER BY
    l_returnflag,
    l_linestatus;
```

In this example, `l_returnflag` and `l_linestatus` fields of the `vops_lineitem_projection` table have the `char` type, while all the other used fields are of vector types. The query above is executed even faster than query with the `map()` and `reduce()` functions. The main problem with this approach is that you have to create a separate projection for each combination of the `GROUP BY` keys to be used in queries.

F.71.5.2.2. Using Vector Window Functions

The `vops` extension provides limited support for Postgres Pro window functions. It provides `mcount`, `msum`, `mmin`, `mmax`, `mavg`, and `lag` functions that correspond to the standard Postgres Pro window functions `count`, `sum`, `min`, `max`, `avg`, and `lag` functions, respectively.

Note the following important restrictions:

1. Filtering, grouping, and sorting can be done only by scalar attributes.

2. Vector window functions only support window frames specified with `ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

Examples:

```
SELECT vops_unnest(t.*)
FROM (SELECT mcount(*) over w,mcount(x) over w,msum(x) over w,mavg(x) over w,mmin(x)
over w,mmax(x) over w,x - lag(x) over w
FROM v window w
AS (rows between unbounded preceding and current row)) t;
```

F.71.5.2.3. Converting Results to Horizontal Format

A query from the `vops` projection returns a set of tiles. The output function of a tile type can print the tile contents. However, if you want to convert the result to the horizontal format where each tuple represents a single record, use the `vops-unnest` function. For example:

```
SELECT vops_unnest(l.*)
FROM vops_lineitem l
WHERE filter(l_shipdate >= '1998-12-01'::date);
```

F.71.5.3. Using Standard SQL for Vector Operations

Vector operators can efficiently execute only filtering and aggregation queries. For other query types, you have to run regular SQL queries. The `vops` extension offers the following options:

- Use the original table, if any.
- Enable a foreign data wrapper (FDW) using `postgres_fdw` to present a vectorized table to Postgres Pro as a regular table with scalar column types.

If you use `postgres_fdw` with the `vops` extension, vectorized data is not really foreign: it is stored inside the database in an alternative vectorized format. FDW allows to hide specifics of the vectorized format and provides the following opportunities for working with vectorized data:

1. Extract the data from a vectorized table and present it in the horizontal format, so that it can be processed by upper nodes in the query execution plan.
2. Push filtering and aggregation queries down to vector operations.
3. Get statistic for the underlying table by running `ANALYZE` for the foreign table. The collected statistic can be used by the query optimizer, so query execution plan should be almost the same as for regular tables.

Thus, by placing a vectorized projection under FDW, you can use standard SQL without any `vops`-specific functions to perform sequential scan and aggregation queries as if they are explicitly written for the `vops` table, and execute any other queries on this data at the same time, including `JOIN` operations, common table expressions (CTE), etc. The queries that can be efficiently executed by vector operations will be pushed by Postgres Pro query optimizer to `vops` FDW and will be executed using vector operators. For other queries, the data is fetched from vectorized tables as standard tuples. If it is determined that vector operations are required, `vops` uses a post-parse `ANALYZE` hook that replaces scalar boolean operations with vector boolean operations:

Original Expression	Transformed Expression
<code>NOT filter(o1)</code>	<code>filter(vops_bool_not(o1))</code>
<code>filter(o1) AND filter(o2)</code>	<code>filter(vops_bool_and(o1, o2))</code>
<code>filter(o1) OR filter(o2)</code>	<code>filter(vops_bool_or(o1, o2))</code>

There is only one difference between standard SQL and its vectorized extension. You still have to perform explicit type cast for string literals. For example, `l_shipdate <= '1998-12-01'` will not work for the `l_shipdate` column with vector type. Postgres Pro Enterprise has two overloaded versions of the `<=` operator to choose the appropriate scalar or vector type:

- `vops_date <= vops_date`

- vops_date <= date

The example below shows creation of a vectorized table via postgres_fdw and some queries on it:

```
CREATE FOREIGN TABLE lineitem_fdw (
    l_suppkey int4 not null,
    l_orderkey int4 not null,
    l_partkey int4 not null,
    l_shipdate date not null,
    l_quantity float8 not null,
    l_extendedprice float8 not null,
    l_discount float8 not null,
    l_tax float8 not null,
    l_returnflag "char" not null,
    l_linestatus "char" not null
) SERVER vops_server OPTIONS (table_name 'vops_lineitem');
```

```
EXPLAIN SELECT
    sum(l_extendedprice*l_discount) AS revenue
FROM
    lineitem_fdw
WHERE
    l_shipdate BETWEEN '1996-01-01' AND '1997-01-01'
    AND l_discount BETWEEN 0.08 AND 0.1
    AND l_quantity < 24;
```

QUERY PLAN

```
-----
Foreign Scan  (cost=1903.26..1664020.23 rows=1 width=4)
(1 row)
```

-- Filter was pushed down to FDW

```
EXPLAIN SELECT
    n_name,
    count(*),
    sum(l_extendedprice * (1-l_discount)) AS revenue
FROM
    customer_fdw JOIN orders_fdw ON c_custkey = o_custkey
    JOIN lineitem_fdw ON l_orderkey = o_orderkey
    JOIN supplier_fdw ON l_suppkey = s_suppkey
    JOIN nation ON c_nationkey = n_nationkey
    JOIN region ON n_regionkey = r_regionkey
WHERE
    c_nationkey = s_nationkey
    AND r_name = 'ASIA'
    AND o_orderdate >= '1996-01-01'
    AND o_orderdate < '1997-01-01'
GROUP BY
    n_name
ORDER BY
    revenue desc;
```

                (cost=0.00..1512151.52 rows=59986176 width=16)
                -> Hash (cost=2790.80..2790.80 rows=7702 width=44)
                    -> Hash Join (cost=40.97..2790.80 rows=7702
width=44)
                        Hash Cond: (supplier_fdw.s_nationkey =
nation.n_nationkey)
                        -> Foreign Scan on supplier_fdw
                        (cost=0.00..2174.64 rows=100032 width=8)
                        -> Hash (cost=40.79..40.79 rows=15
width=36)
                            -> Hash Join (cost=20.05..40.79
rows=15 width=36)
                                Hash Cond: (nation.n_regionkey
= region.r_regionkey)
                                -> Seq Scan on nation
                                (cost=0.00..17.70 rows=770 width=40)
                                -> Hash (cost=20.00..20.00
rows=4 width=4)
                                    -> Seq Scan on region
                                    (cost=0.00..20.00 rows=4 width=4)
                                        Filter:
((r_name)::text = 'ASIA'::text)
                                        -> Hash (cost=294718.76..294718.76 rows=2284376 width=8)
                                        -> Foreign Scan on orders_fdw (cost=0.00..294718.76
rows=2284376 width=8)
                                        -> Hash (cost=32605.64..32605.64 rows=1500032 width=8)
                                        -> Foreign Scan on customer_fdw (cost=0.00..32605.64
rows=1500032 width=8)

-- filter on orders range is pushed to FDW

```

F.71.5.4. Building Indexes for Vectorized Tables

Analytic queries are usually performed on the data for which no indexes are defined. Vector operations on tiles are most effective in this case. However, you can still use indexes with vectorized data.

Since each tile represents multiple values, an index can be used only for some preliminary, non-precise filtering of data. The `vops` extension provides the following pairs of functions to obtain boundary values stored in the tile:

- `first()` and `last()` functions should be used for sorted dataset. In this case, the first and the last values in the tile are the smallest and the largest values in the tile, respectively.
- `high()` and `low()` functions should be used for unsorted data. These functions are more expensive because they need to inspect all tile values.

Using the returned values, you can construct functional indexes for vectorized data. The BRIN index seems to be the best choice:

```
CREATE INDEX low_boundary ON trades
USING brin(first(day)); -- trades table is ordered by day
CREATE INDEX high_boundary ON trades
USING brin(last(day)); -- trades table is ordered by day
```

Now you can use the created indexes in queries. However, you have to recheck the precise condition because such an index only gives an approximate result:

```
SELECT sum(price) FROM trades
WHERE first(day) >= '2015-01-01' AND last(day) <= '2016-01-01'
AND filter(betwixt(day, '2015-01-01', '2016-01-01'));
```

F.71.5.5. Automating Projection Usage

`vops` can automate most of the operations required to create and maintain vectorized data projections. In this case, you do not have to use [postgres_fdw](#): `vops` can redirect regular SQL queries to projection tables automatically. However, these queries must satisfy the following criteria to get redirected:

- The query does not contain joins.
- The query performs aggregation of vector columns.
- All other expressions in the target list, as well as `ORDER BY` and `GROUP BY` clauses refer only to scalar columns.

To enable automatic query redirection to a vectorized projection of your data, do the following:

1. Create a vectorized projection of the table using the `create_projection()` function.

For example, to create a projection for the `lineitem` table shown above, similar to the `vops_lineitem`, run:

```
SELECT create_projection('auto_vops_lineitem', 'lineitem',
    array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
    array['l_returnflag', 'l_linestatus']);
```

In this example, the first two arguments specify the projection table and the original table, respectively, the first array defines all the vector columns to be included into the projection, and the second array specifies the scalar columns that will be used for grouping vectorized data into tiles.

Additionally, you can provide an optional `order_by` parameter to speed up subsequent projection refresh operations. The `order_by` values should be unique. For example, to sort all table entries by `l_shipdate`, you can create a projection table as follows:

```
SELECT create_projection('auto_vops_lineitem_ordered', 'lineitem',
    array['l_shipdate', 'l_quantity', 'l_extendedprice', 'l_discount', 'l_tax'],
    array['l_returnflag', 'l_linestatus'],
    'l_shipdate');
```

2. Set the `vops.auto_substitute_projections` parameter to `on`.

Now all queries that `vops` can redirect to the `auto_vops_lineitem` projection table will be run on the vectorized data.

Projections are not updated automatically, so once the original table gets updated, implicitly redirected queries can start returning inaccurate results. To avoid this, you have to refresh the projections before running queries on the vectorized data. For this purpose, `vops` provides the `pname_refresh()` functions, where the `pname` prefix is the name of the projection you need to refresh. For example, to refresh the `auto_vops_lineitem` projection, run:

```
SELECT auto_vops_lineitem_refresh();
```

This function calls the `populate()` method to update all the fields present in the projection. If you have specified the optional `order_by` parameter when creating the projection, only the new data will be im-

ported from the original table, selecting only the rows with the `order_by` column value greater than the maximal value of this column in the projection. Otherwise, the whole table will be re-written. The `populate()` method also takes the grouping columns into account to efficiently group the imported data in tiles.

If you have specified the `order_by` attribute when creating a projection, `vops` also creates the following indexes:

- Two functional BRIN indexes on `first()` and `last()` functions of this attribute. Such indexes allow to efficiently select time slices. For example, if the original query contains predicates like `(l_shipdate between '01-01-2017' and '01-01-2018')`, `vops` adds the `(first(l_shipdate) >= '01-01-2017' and last(l_shipdate) >= '01-01-2018')` conjuncts when redirecting the query, so that Postgres Pro optimizer can quickly locate the affected pages using BRIN indexes.
- A BRIN index for scalar columns used for grouping. Such index allows to efficiently select groups and perform index joins.

F.71.6. Reference

F.71.6.1. Vector Types

The `vops` extension supports all basic Postgres Pro numeric types: 1-, 2-, 4-, 8-byte integers, as well as 4- and 8-byte floats. The `date` and `timestamp` types are using the same implementation as `int4` and `int8`, respectively. The table below illustrates the available vector types, as compared to the corresponding SQL and C types.

SQL Type	C Type	<code>vops</code> Vector Type
<code>bool</code>	<code>bool</code>	<code>vops_bool</code>
<code>"char"</code>	<code>char</code>	<code>vops_char</code>
<code>date</code>	<code>DateADT</code>	<code>vops_date</code>
<code>int2</code>	<code>int16</code>	<code>vops_int2</code>
<code>int4</code>	<code>int32</code>	<code>vops_int4</code>
<code>int8</code>	<code>int64</code>	<code>vops_int8</code>
<code>float4</code>	<code>float4</code>	<code>vops_float4</code>
<code>float8</code>	<code>float8</code>	<code>vops_float8</code>
<code>timestamp</code>	<code>Timestamp</code>	<code>vops_timestamp</code>
<code>char(N)</code> , <code>varchar(N)</code>	<code>text</code>	<code>vops_text(N)</code>

Note

For performance reasons, using `vops_text` for single-character strings is not recommended. If you are using strings as identifiers, you can place them in a dictionary and use integer identifiers instead of the original strings.

F.71.6.2. Vector Operators

The `vops` extension provides a set of operators for vector types.

F.71.6.2.1. Mathematical Operators

For mathematical operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

Operator	Description
<code>+</code>	Addition

Operator	Description
–	Binary subtraction or unary negation
*	Multiplication
/	Division
	Concatenation. This operator is only supported for <code>char</code> , <code>int2</code> , and <code>int4</code> types. It returns an integer type of a doubled size: <code>(char char) -> int2</code> <code>(int2 int2) -> int4</code> <code>(int4 int4) -> int8</code>

F.71.6.2.2. Comparison Operators

For comparison operations, `vops` overloads regular SQL operators, so they can take operands of both vector and scalar types.

Operator	Description
=	Equals
<>	Not equals
<	Less than
<=	Less than or equals
>	Greater than
>=	Greater than or equals

F.71.6.2.3. Boolean Operators

Boolean operators `AND`, `OR`, and `NOT` cannot be overloaded, so `vops` provides its own implementation of boolean operators for vector types:

Operator	Description
&	Boolean AND
	Boolean OR
!	Boolean NOT

Vector boolean operators have the following usage specifics:

- The precedence of vector boolean operators is different from `AND`, `OR`, and `NOT`, so you have to enclose the operands into parentheses. For example:
`(x=1) | (x=2)`
- The result of vector boolean operations is `vops_bool`. Since Postgres Pro requires predicate expressions to have a regular boolean type, you have to convert the result to the `bool` type using the `filter()` function. Taking a vector boolean expression, this function calculates a `filter_mask` value that defines the result of this boolean operation for each vector element. If all mask bits are zero (the predicate is false for all vector elements), then `filter()` returns `false`, and Postgres Pro executor skips this record. Otherwise, `true` is returned, so vector operators will check the `filter_mask` value for the selected vector elements in subsequent operations.
- When using vector boolean operators, you have to use explicit cast of string constants to the required data type.

F.71.6.3. Comparison Functions

Function	Description
<code>bitwixt(x, low, high)</code>	Same as the <code>x BETWEEN low AND high</code> predicate.

Function	Description
<code>is_null(x)</code>	Same as the <i>expression</i> IS NULL predicate.
<code>is_not_null(x)</code>	Same as the <i>expression</i> IS NOT NULL predicate.
<code>ifnull(x, subst)</code>	Same as the COALESCE function.

F.71.6.4. Conversion Functions

```
create_projection(projection_name text, source_table regclass, vector_columns text[],
scalar_columns text[] DEFAULT null, order_by text DEFAULT null)
```

Creates a projection table with specified name and attributes and updates the `vops_projections` table to include the information about this projection, so that the optimizer can automatically redirect queries from the original table to its projection. It also creates the `pname_refresh()` function that can update the projection.

Arguments:

- *projection_name* — the name of the projection table.
- *source_table* — the original Postgres Pro table for which to create a vectorized projection.
- *vector_columns* — an array of column names that will be stored as `vops` tiles.
- *scalar_columns* — an array of column names that will preserve its original scalar type. These columns will be used to group table rows into `vops` tiles. `vops` automatically builds a BRIN index over such columns.
- *order_by* — an optional vector column that can be used to sort data in the projection table. Sorting can be useful to incrementally update the projection after the original table updates using the `pname_refresh()` function. This column should contain unique timestamp values, such as trade dates. `vops` automatically builds a functional BRIN index for `first()` and `last()` functions of this column.

Examples:

```
SELECT
  create_projection('vops_lineitem', 'lineitem', array['l_shipdate', 'l_quantity', 'l_extended
pname_refresh()
```

Refreshes the *pname* projection table.

Examples:

Refresh the `vops_lineitem` projection:

```
SELECT vops_lineitem_refresh();
drop_projection(projection_name text)
```

Drops the specified projection and the corresponding refresh function, as well as removes the information about this projection from the `vops_projections` table.

Examples:

Drop the `vops_lineitem` projection:

```
SELECT drop_projection(vops_lineitem);
populate(destination regclass, source regclass, predicate cstring DEFAULT null, sort
cstring DEFAULT null)
```

Copies the data from an existing table to its vectorized projection and returns the number of imported rows (`bigint`).

Arguments:

- *destination* — target table to copy the data into.

Type: regclass

- *source* — source table to copy the data from.

Type: regclass

- *predicate* — restricts the amount of imported data (optional). Using this argument, you can upload only the most recent records.

Type: cstring

- *sort* — sorts the source data to define the order in which the data needs to be loaded (optional).

Type: cstring

Examples:

```
SELECT populate(destination := 'vops_lineitem'::regclass, source :=  
  'lineitem'::regclass);
```

```
SELECT populate(destination := 'vops_lineitem_projection'::regclass, source :=  
  'lineitem_projection'::regclass, sort := 'l_returnflag,l_linestatus');
```

```
import(destination regclass, csv_path cstring, separator cstring DEFAULT ',', skip integer  
DEFAULT 0)
```

Loads the data into a `vops` table directly from a CSV file, bypassing creation of a regular table, and returns the number of imported rows (`bigint`). Use this function to avoid storing two copies of the same dataset.

Arguments:

- *destination* — target table to copy the data into.

Type: regclass

- *csv_path* — the path to the CSV file to copy the data from.

Type: cstring

- *separator* — specifies the field separator used in the CSV file (optional). By default, the comma is assumed to be the field separator.

Type: cstring

- *skip* — specifies the number of rows in the CSV header that do not need to be imported (optional).

Default: 0

Type: cstring

Examples:

```
SELECT import(destination := 'vops_lineitem'::regclass, csv_path := '/mnt/data/  
lineitem.csv', separator := '|');
```

```
vops_unnest(anyelement)
```

Scatters records with `vops` types into records with scalar types.

F.71.6.5. Configuration Parameters

`vops.auto_substitute_projections` (boolean)

Enables automatic query redirection to projection tables. For correct results, you have to ensure that the projection is synchronized with the original table.

Default: `off`

F.71.7. Authors

Postgres Professional, Moscow, Russia

F.72. xml2

The `xml2` module provides XPath querying and XSLT functionality.

F.72.1. Deprecation Notice

From PostgreSQL 8.3 on, there is XML-related functionality based on the SQL/XML standard in the core server. That functionality covers XML syntax checking and XPath queries, which is what this module does, and more, but the API is not at all compatible. It is planned that this module will be removed in a future version of Postgres Pro in favor of the newer standard API, so you are encouraged to try converting your applications. If you find that some of the functionality of this module is not available in an adequate form with the newer API, please explain your issue to pgsql-hackers@lists.postgresql.org so that the deficiency can be addressed.

F.72.2. Description of Functions

[Table F.123](#) shows the functions provided by this module. These functions provide straightforward XML parsing and XPath queries.

Table F.123. `xml2` Functions

Function	Description
<code>xml_valid (document text) → boolean</code>	Parses the given document and returns true if the document is well-formed XML. (Note: this is an alias for the standard Postgres Pro function <code>xml_is_well_formed()</code> . The name <code>xml_valid()</code> is technically incorrect since validity and well-formedness have different meanings in XML.)
<code>xpath_string (document text, query text) → text</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>text</code> .
<code>xpath_number (document text, query text) → real</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>real</code> .
<code>xpath_bool (document text, query text) → boolean</code>	Evaluates the XPath query on the supplied document, and casts the result to <code>boolean</code> .
<code>xpath_nodeset (document text, query text, toptag text, itemtag text) → text</code>	Evaluates the query on the document and wraps the result in XML tags. If the result is multi-valued, the output will look like: <pre><toptag> <itemtag>Value 1 which could be an XML fragment</itemtag> <itemtag>Value 2....</itemtag> </toptag></pre> If either <code>toptag</code> or <code>itemtag</code> is an empty string, the relevant tag is omitted.

Function	Description
<code>xpath_node</code> (<i>document</i> text, <i>query</i> text, <i>itemtag</i> text) → text Like <code>xpath_node</code> (document, query, toptag, itemtag) but result omits <i>toptag</i> .	
<code>xpath_node</code> (<i>document</i> text, <i>query</i> text) → text Like <code>xpath_node</code> (document, query, toptag, itemtag) but result omits both tags.	
<code>xpath_list</code> (<i>document</i> text, <i>query</i> text, <i>separator</i> text) → text Evaluates the query on the document and returns multiple values separated by the specified separator, for example Value 1, Value 2, Value 3 if <i>separator</i> is , .	
<code>xpath_list</code> (<i>document</i> text, <i>query</i> text) → text This is a wrapper for the above function that uses , as the separator.	

F.72.3. xpath_table

`xpath_table`(text key, text document, text relation, text xpaths, text criteria) returns setof record

`xpath_table` is a table function that evaluates a set of XPath queries on each of a set of documents and returns the results as a table. The primary key field from the original document table is returned as the first column of the result so that the result set can readily be used in joins. The parameters are described in [Table F.124](#).

Table F.124. xpath_table Parameters

Parameter	Description
<i>key</i>	the name of the “key” field — this is just a field to be used as the first column of the output table, i.e., it identifies the record from which each output row came (see note below about multiple values)
<i>document</i>	the name of the field containing the XML document
<i>relation</i>	the name of the table or view containing the documents
<i>xpaths</i>	one or more XPath expressions, separated by
<i>criteria</i>	the contents of the WHERE clause. This cannot be omitted, so use true or 1=1 if you want to process all the rows in the relation

These parameters (except the XPath strings) are just substituted into a plain SQL SELECT statement, so you have some flexibility — the statement is

```
SELECT <key>, <document> FROM <relation> WHERE <criteria>
```

so those parameters can be *anything* valid in those particular locations. The result from this SELECT needs to return exactly two columns (which it will unless you try to list multiple fields for key or document). Beware that this simplistic approach requires that you validate any user-supplied values to avoid SQL injection attacks.

The function has to be used in a FROM expression, with an AS clause to specify the output columns; for example

```
SELECT * FROM
xpath_table('article_id',
            'article_xml',
            'articles',
            '/article/author|/article/pages|/article/title',
            'date_entered > ''2003-01-01'' ')
AS t(article_id integer, author text, page_count integer, title text);
```

The `AS` clause defines the names and types of the columns in the output table. The first is the “key” field and the rest correspond to the XPath queries. If there are more XPath queries than result columns, the extra queries will be ignored. If there are more result columns than XPath queries, the extra columns will be `NULL`.

Notice that this example defines the `page_count` result column as an integer. The function deals internally with string representations, so when you say you want an integer in the output, it will take the string representation of the XPath result and use Postgres Pro input functions to transform it into an integer (or whatever type the `AS` clause requests). An error will result if it can't do this — for example if the result is empty — so you may wish to just stick to `text` as the column type if you think your data has any problems.

The calling `SELECT` statement doesn't necessarily have to be just `SELECT *` — it can reference the output columns by name or join them to other tables. The function produces a virtual table with which you can perform any operation you wish (e.g., aggregation, joining, sorting etc). So we could also have:

```
SELECT t.title, p.fullname, p.email
FROM xpath_table('article_id', 'article_xml', 'articles',
                '/article/title|article/author/@id',
                'xpath_string(article_xml, '/article/@date') > ''2003-03-20'' ')
     AS t(article_id integer, title text, author_id integer),
     tblPeopleInfo AS p
WHERE t.author_id = p.person_id;
```

as a more complicated example. Of course, you could wrap all of this in a view for convenience.

F.72.3.1. Multivalued Results

The `xpath_table` function assumes that the results of each XPath query might be multivalued, so the number of rows returned by the function may not be the same as the number of input documents. The first row returned contains the first result from each query, the second row the second result from each query. If one of the queries has fewer values than the others, null values will be returned instead.

In some cases, a user will know that a given XPath query will return only a single result (perhaps a unique document identifier) — if used alongside an XPath query returning multiple results, the single-valued result will appear only on the first row of the result. The solution to this is to use the key field as part of a join against a simpler XPath query. As an example:

```
CREATE TABLE test (
    id int PRIMARY KEY,
    xml text
);

INSERT INTO test VALUES (1, '<doc num="C1">
<line num="L1"><a>1</a><b>2</b><c>3</c></line>
<line num="L2"><a>11</a><b>22</b><c>33</c></line>
</doc>');

INSERT INTO test VALUES (2, '<doc num="C2">
<line num="L1"><a>111</a><b>222</b><c>333</c></line>
<line num="L2"><a>111</a><b>222</b><c>333</c></line>
</doc>');

SELECT * FROM
    xpath_table('id','xml','test',
                '/doc/@num|doc/line/@num|doc/line/a|doc/line/b|doc/line/c',
                'true')
     AS t(id int, doc_num varchar(10), line_num varchar(10), val1 int, val2 int, val3 int)
WHERE id = 1 ORDER BY doc_num, line_num
```

id	doc_num	line_num	val1	val2	val3
1	C1	L1	1	2	3
1		L2	11	22	33

To get `doc_num` on every line, the solution is to use two invocations of `xpath_table` and join the results:

```
SELECT t.*,i.doc_num FROM
  xpath_table('id', 'xml', 'test',
              '/doc/line/@num|/doc/line/a|/doc/line/b|/doc/line/c',
              'true')
  AS t(id int, line_num varchar(10), val1 int, val2 int, val3 int),
  xpath_table('id', 'xml', 'test', '/doc/@num', 'true')
  AS i(id int, doc_num varchar(10))
WHERE i.id=t.id AND i.id=1
ORDER BY doc_num, line_num;
```

id	line_num	val1	val2	val3	doc_num
1	L1	1	2	3	C1
1	L2	11	22	33	C1

(2 rows)

F.72.4. XSLT Functions

The following functions are available if `libxslt` is installed:

F.72.4.1. `xslt_process`

`xslt_process(text document, text stylesheet, text paramlist)` returns text

This function applies the XSL stylesheet to the document and returns the transformed result. The `paramlist` is a list of parameter assignments to be used in the transformation, specified in the form `a=1,b=2`. Note that the parameter parsing is very simple-minded: parameter values cannot contain commas!

There is also a two-parameter version of `xslt_process` which does not pass any parameters to the transformation.

F.72.5. Author

John Gray <jgray@azuli.co.uk>

Development of this module was sponsored by Torchbox Ltd. (www.torchbox.com). It has the same BSD license as Postgres Pro.

Appendix G. Additional Supplied Programs

This appendix and the previous one contain information regarding additional modules available in the Postgres Pro Enterprise distribution. See [Appendix F](#) for more information about the server extensions and plug-ins.

This appendix covers the utility programs. Once installed, they are found in the `bin` directory of the Postgres Pro Enterprise installation and can be used like any other program.

G.1. Client Applications

This section covers Postgres Pro Enterprise client applications. They can be run from anywhere, independent of where the database server resides. See also [Postgres Pro Client Applications](#) for information about client applications that are part of the core Postgres Pro Enterprise distribution.

oid2name

oid2name — resolve OIDs and file nodes in a Postgres Pro data directory

Synopsis

```
oid2name [option...]
```

Description

oid2name is a utility program that helps administrators to examine the file structure used by Postgres Pro. To make use of it, you need to be familiar with the database file structure, which is described in [Chapter 69](#).

Note

The name “oid2name” is historical, and is actually rather misleading, since most of the time when you use it, you will really be concerned with tables' filenode numbers (which are the file names visible in the database directories). Be sure you understand the difference between table OIDs and table filenodes!

oid2name connects to a target database and extracts OID, filenode, and/or table name information. You can also have it show database OIDs or tablespace OIDs.

Options

oid2name accepts the following command-line arguments:

```
-f filenode
```

```
--filenode=filenode
```

show info for table with filenode *filenode*.

```
-i
```

```
--indexes
```

include indexes and sequences in the listing.

```
-o oid
```

```
--oid=oid
```

show info for table with OID *oid*.

```
-q
```

```
--quiet
```

omit headers (useful for scripting).

```
-s
```

```
--tablespaces
```

show tablespace OIDs.

```
-S
```

```
--system-objects
```

include system objects (those in `information_schema`, `pg_toast` and `pg_catalog` schemas).

```
-t tablename_pattern
```

```
--table=tablename_pattern
```

show info for table(s) matching *tablename_pattern*.

`-V`
`--version`
Print the oid2name version and exit.

`-x`
`--extended`
display more information about each object shown: tablespace name, schema name, and OID.

`-?`
`--help`
Show help about oid2name command line arguments, and exit.

oid2name also accepts the following command-line arguments for connection parameters:

`-d database`
`--dbname=database`
database to connect to.

`-h host`
`--host=host`
database server's host.

`-H host`
database server's host. Use of this parameter is *deprecated* as of Postgres Pro 12.

`-p port`
`--port=port`
database server's port.

`-U username`
`--username=username`
user name to connect as.

To display specific tables, select which tables to show by using `-o`, `-f` and/or `-t`. `-o` takes an OID, `-f` takes a filenode, and `-t` takes a table name (actually, it's a `LIKE` pattern, so you can use things like `foo%`). You can use as many of these options as you like, and the listing will include all objects matched by any of the options. But note that these options can only show objects in the database given by `-d`.

If you don't give any of `-o`, `-f` or `-t`, but do give `-d`, it will list all tables in the database named by `-d`. In this mode, the `-s` and `-i` options control what gets listed.

If you don't give `-d` either, it will show a listing of database OIDs. Alternatively you can give `-s` to get a tablespace listing.

Environment

`PGHOST`
`PGPORT`
`PGUSER`

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

oid2name requires a running database server with non-corrupt system catalogs. It is therefore of only limited use for recovering from catastrophic database corruption situations.

Examples

```
$ # what's in this database server, anyway?
$ oid2name
All databases:
  Oid   Database Name   Tablespace
-----
 17228      alvherre   pg_default
 17255      regression pg_default
 17227      template0  pg_default
    1      template1  pg_default

$ oid2name -s
All tablespaces:
  Oid   Tablespace Name
-----
  1663      pg_default
  1664      pg_global
155151      fastdisk
155152      bigdisk

$ # OK, let's look into database alvherre
$ cd $PGDATA/base/17228

$ # get top 10 db objects in the default tablespace, ordered by size
$ ls -lS * | head -10
-rw----- 1 alvherre alvherre 136536064 sep 14 09:51 155173

pgbadger

pgbadger — rapidly analyze Postgres Pro logs, producing detailed reports and graphs

Synopsis

```
pgbadger [connection-option...] [option...] [logfile...]
```

Description

pgbadger is a Postgres Pro/PostgreSQL log analyzer, which rapidly provides detailed reports based on your log files. pgbadger is provided with Postgres Pro as a standalone Perl script.

logfile can be a single log file, a list of files or a shell command that returns a list of files. To get log content from the standard input, pass “-” as *logfile*.

pgbadger can parse huge log files and compressed files. It can autodetect your log file format (syslog, stderr, csvlog or jsonlog) if the file is long enough. Supported compressed formats are gzip, bzip2, lz4, xz, zip and zstd. For the xz format, you must have an xz version higher than 5.05, which supports the `--robot` option. For pgbadger to determine the uncompressed file size for the lz4 format, the file must be compressed with the `--content-size` option.

pgbadger supports any format of log-line prefixes that can be specified through the `log_line_prefix` configuration setting of your `postgresql.conf` configuration file, provided that at least `%t` and `%p` are specified.

[pgbouncer](#) log files can also be parsed.

To speed up log parsing, you can use any of these multiprocessing modes: one core per log file and multiple cores per file. These modes can be combined.

pgbadger can also parse remote log files fetched using a passwordless SSH connection. This mode can be used with compressed files and even supports multiprocessing with multiple cores per file.

Examples of reports can be found at <https://pgbadger.darold.net/#reports>.

Limitations

pgbadger currently has the following limitations:

- Multiprocessing is not supported for compressed log files and CSV files, as well as on Windows.
- CSV format of log files cannot be parsed remotely.
- csvlog logs cannot be passed from the standard input.

Setup and Configuring

Once you have pgbadger installed, complete the setup described in sections below.

[Optional] Set up Parsing Specific Log Formats

If you plan to parse CSV log files, install `Text::CSV_XS` Perl module.

[Optional] Set up Export of Statistics

If you want to export statistics as a JSON file, install `JSON::XS` Perl module:

To install this optional module:

- On a Debian-based system, run:

```
sudo apt-get install libjson-xs-perl
```

- On an RPM system, run:

```
sudo yum install perl-JSON-XS
```

[Optional] Set up Parsing Compressed Log Files

By default, pgbadger autodetects the compressed log file format from the file extension and uses decompression utilities accordingly:

- `zcat` for `gz`
- `bzcat` for `bz2`
- `lz4cat` for `lz4`
- `zstdcat` for `zst`
- `unzip` or `xz` for `zip` or `xz`

If the needed utility is outside of your `PATH` directories, use the `--zcat` command-line option to specify the path to the decompression utility. For example:

```
--zcat="/usr/local/bin/gunzip -c" or --zcat="/usr/local/bin/bzip2 -dc"  
--zcat="C:\tools\unzip -p"
```

Note

With the default autodetection of the compressed file format, you can mix `gz`, `bz2`, `lz4`, `xz`, `zip` and `zstd` log files. Once you specified a custom value of `--zcat`, mixing compressed files of different formats is longer possible.

Configure Your Postgres Pro Server

Set the values of certain configuration parameters in your `postgresql.conf`:

- Set up logging SQL queries.

To enable SQL query logging and have the query statistics include actual query strings, set

```
log_min_duration_statement = 0
```

On a busy server you may want to increase this value to only log queries with a longer duration.

If you just want to report the duration and number of queries and do not want details of queries, set `log_min_duration_statement` to `-1`, which disables logging statement durations, and enable `log_duration`.

Enabling `log_min_duration_statement` will add reports about slowest queries and queries that took the most time. Note that if you set `log_statement` to `all`, the setting of `log_min_duration_statement` will have no effect.

Warning

Avoid setting `log_min_duration_statement` to a non-positive value together with enabling `log_duration` and `log_statement` as this will result in wrong counter values and drastically increase the size of your log. Always prefer setting `log_min_duration_statement`.

- Set the log line prefix string in `log_line_prefix`.

It must at least include a time escape sequence (`%t`, `%m` or `%n`) and the process-related escape sequence (`%p` or `%c`). For example, for `stderr` logs, the setting must be at least

```
log_line_prefix = '%t [%p]: '
```

The log line prefix could also specify the user, database name, application name and client IP address. For example,

for stderr logs:

```
log_line_prefix = '%t [%p]: user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = '%t [%p]: db=%d,user=%u,app=%a,client=%h '
```

and for syslog logs:

```
log_line_prefix = 'user=%u,db=%d,app=%a,client=%h '
```

or

```
log_line_prefix = 'db=%d,user=%u,app=%a,client=%h '
```

- To get more information from your log files, set certain configuration parameters as follows:

```
log_checkpoints = on
log_connections = on
log_disconnections = on
log_lock_waits = on
log_temp_files = 0
log_autovacuum_min_duration = 0
log_error_verbosity = default
```

To benefit from these settings, do not enable [log_statement](#) as pgbadger does not parse the corresponding log format.

- Set the language in which messages are displayed; messages must be in English with or without locale support:

```
lc_messages='C'
```

or

```
lc_messages='en_US.UTF-8'
```

Locales for other languages, such as `ru_RU.utf8`, are not supported.

Usage

The following are simple examples to illustrate miscellaneous pgbadger usage details.

```
pgbadger /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-13/data/log/postgres.log.2.gz /var/lib/pgpro/ent-13/data/
log/postgres.log.1.gz /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-14_000000.log
pgbadger /var/lib/pgpro/ent-13/data/log/postgresql/postgresql-2022-01-*
pgbadger --exclude-query="^(COPY|COMMIT)" /var/lib/pgpro/ent-13/data/log/
postgresql-2022-01-14_000000.log
pgbadger -b "2022-01-25 10:56:11" -e "2022-01-25 10:59:11" /var/lib/pgpro/ent-13/data/
log/postgresql-2022-01-25-0000.log
cat /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-14_000000.log | pgbadger -
# Log line prefix with stderr log output
pgbadger --prefix '%t [%p]: user=%u,db=%d,client=%h' /var/lib/pgpro/ent-13/data/log/
postgresql-2022-08-21*
pgbadger --prefix '%m %u@d %p %r %a : ' /var/lib/pgpro/ent-13/data/log/
postgresql-2022-08-21-0000.log
# Log line prefix with syslog log output
pgbadger --prefix 'user=%u,db=%d,client=%h,appname=%a' /var/lib/pgpro/ent-13/data/log/
postgresql-2022-08-21*
# Use 8 CPUs to parse 10GB file faster
```

```
pgbadger -j 8 /var/lib/pgpro/ent-13/data/log/postgresql-2022-08-21-0000.log
# Use a cron job to report errors weekly
30 23 * * 1 /usr/bin/pgbadger -q -w /var/lib/pgpro/ent-13/data/log/
postgresql-2022-01*.log -o /var/www/pg_reports/pg_errors.html
```

Specifying Remote Log Files

Specify remote log files to parse using a URI. Supported protocols are HTTP[S] and [S]FTP. The `curl` command will be used to download the file, and the file will be parsed during download. The SSH protocol is also supported and will use the `ssh` command to get log files, as when the `--remote-host` option is used.

Use these URI notations for the remote log file:

```
pgbadger http://172.12.110.1//var/lib/pgpro/ent-13/data/log/
postgresql-2022-01-14_000000.log
pgbadger ftp://username@172.12.110.14/postgresql-2022-01-14_000000.log
pgbadger ssh://username@172.12.110.14:2222//var/lib/pgpro/ent-13/data/log/
postgresql-2022-01-14_000000.log*
```

You can parse a local Postgres Pro log and a remote [pgbouncer](#) log file together:

```
pgbadger /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-14_000000.log ssh://
username@172.12.110.14/pgbouncer.log
```

Parallel Processing

To enable parallel processing, specify the `-j N` option, where *N* is the number of cores to use.

Parallel processing in pgbadger follows the algorithm below:

```
For each log file
  chunk size = int(file size / N)
  look at start/end offsets of these chunks
  fork N processes and seek to the start offset of each chunk
    each process will terminate when the parser reaches the end offset of its chunk
    each process writes stats into a binary temporary file
  wait for all child processes to terminate
All binary temporary files generated will then be read and loaded into
memory to build the html output.
```

With this method, at start/end of chunks pgbadger may truncate or omit a maximum of *N* queries per log file, which is an insignificant gap if you have millions of queries in your log file. The chance that the query that you were looking for is lost is near zero, so this gap can be considered suitable. Most of the time the query is counted twice, but truncated.

When you have many small log files and many CPUs, it is faster to dedicate one core to one log file at a time. To enable this behavior, specify the `-J N` option instead. Using this method, you can be sure not to lose any queries in the reports. With 200 log files of 10 MB each, the `-J` option starts being really efficient with 8 cores.

Here is a benchmark done on a server with 8 CPUs and a single file of 9.5 GB.

Option	1 CPU	2 CPU	4 CPU	8 CPU
-j	1h41m18	50m25	25m39	15m58
-J	1h41m18	54m28	41m16	34m45

With 200 log files of 10 MB each, which is 2 GB in total, the results are slightly different:

Option	1 CPU	2 CPU	4 CPU	8 CPU
-j	1h41m18	50m25	25m39	15m58
-J	1h41m18	54m28	41m16	34m45

```
-j      | 20m15 | 9m56 | 5m20 | 4m20  
-J      | 20m15 | 9m49 | 5m00 | 2m40
```

So it is recommended to use the `-j` option unless you have hundreds of small log files and can use at least 8 CPUs.

Important

During parallel parsing, `pgbadger` generates a lot of temporary files named `tmp_pgbadgerXXXX.bin` in the `/tmp` directory and removes them at the end.

Building Incremental Reports

The following sample cron job builds a report every week with the incremental behavior assuming that your log file and HTML report are also rotated every week:

```
0 4 * * 1 /usr/bin/pgbadger -q `find /var/lib/pgpro/ent-13/data/log/ -mtime -7 -name  
"postgresql.log*"` -o /var/www/pg_reports/pg_errors-`date +%F`.html -l /var/reports/  
pgbadger_incremental_file.dat
```

But better turn on `pgbadger`'s automatic building incremental reports by specifying the `-I/--incremental` option. In this mode, `pgbadger` builds one report per day and a cumulative report per week. The output is first built in the binary format and saved to the output directory, specified by the `-O/--outdir` option, and then daily and weekly reports are built in the HTML format with the main index file. The main index file shows a dropdown menu per week with a link to the week's report and links to daily reports for that week. For example, run `pgbadger` as follows with the file rotated daily:

```
0 4 * * * /usr/bin/pgbadger -I -q /var/lib/pgpro/ent-13/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

You will have all daily and weekly reports. In this mode `pgbadger` will automatically create an incremental file in the output directory, so you do not have to use the `-l` option unless you want to change the path of that file. This means that you can run `pgbadger` in this mode every day on a log file rotated every week and it will not count the log entries twice. To save disk space, you may want to use the `-x/--extra-files` command-line option to force `pgbadger` to write CSS and JavaScript files to the output directory as separate files. The resources will then be loaded using script and link tags.

In the incremental mode, you can also specify the number of weeks to keep in the report by using the `-O/--retention` option:

```
/usr/bin/pgbadger --retention 2 -I -q /var/lib/pgpro/ent-13/data/log/postgresql/  
postgresql.log.1 -O /var/www/pg_reports/
```

If `pg_dump` is scheduled to run at 23:00 and 13:00 every day, you can exclude these periods from the report as follows:

```
pgbadger --exclude-time "2013-09-.* (23|13):.*" postgresql.log
```

This will help avoid having `COPY` statements generated by `pg_dump` on top of the list of slowest queries. Alternatively, you can use `--exclude-appname "pg_dump"` to solve this problem in a simpler way.

Rebuilding Reports

To update all HTML reports after fixing a `pgbadger` report or adding a new feature to it, you can rebuild incremental reports. To rebuild all reports in the case a binary file is still available, run:

```
rm /path/to/reports/*.js  
rm /path/to/reports/*.css  
pgbadger -X -I -O /var/www/pg_reports/ --rebuild
```

This will also update all the resource files (JavaScript and CSS). Use the `-E/--explode` option if the reports were built with this option.

Building Monthly Reports

By default, in the incremental mode pgbadger only computes daily and weekly reports. To have monthly cumulative reports, you will need to use a separate command to specify the report to build. For example, to build a report for August 2021, run:

```
pgbadger -X --month-report 2021-08 /var/www/pg_reports/
```

This will add a link to the month name to the calendar view of incremental reports to look at the monthly report. The report for a current month can be run every day, and it is entirely rebuilt each time. The monthly report is not built by default because it could take too long. Like when rebuilding reports, if reports were built with the per-database option (`-E/--explode`), it must be used to build the monthly report:

```
pgbadger -E -X --month-report 2021-08 /var/www/pg_reports/
```

Choosing the Report File Format

The pgbadger report file format is determined by the extension of the file passed to the `-o/--outfile` option.

Use the binary format (`-o *.bin`) to create custom incremental and cumulative reports.

For example, to refresh a pgbadger report every hour from a daily log file, you can run the following commands every hour:

```
# Generate incremental data files in the binary format
pgbadger --last-parsed .pgbadger_last_state_file -o sunday/hourX.bin /var/lib/pgpro/
ent-13/data/log/postgresql-Sun.log
# Build a fresh HTML report from the generated binary file
pgbadger sunday/*.bin
```

For another example, assume that you generate one log file per hour. To have reports rebuilt each time the log file is rotated, run:

```
pgbadger -o day1/hour01.bin /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-23_10.log
pgbadger -o day1/hour02.bin /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-23_11.log
pgbadger -o day1/hour03.bin /var/lib/pgpro/ent-13/data/log/postgresql-2022-01-23_12.log
...
```

And to refresh the HTML report, for example, each time after a new binary file is generated, just run:

```
pgbadger -o day1_report.html day1/*.bin
```

Adjust the commands to your particular needs.

Use the JSON format (`-o *.json`) to share data with other languages and to facilitate integration of pgbadger output with other monitoring tools, such as Cacti or Graphite.

Select other output formats to meet your particular needs. For example, this command will generate *Tsung* sessions XML file for `SELECT` queries only:

```
pgbadger -S -o sessions.tsung --prefix '%t [%p]: user=%u,db=%d ' /var/lib/pgpro/
ent-13/data/log/postgresql-2022-01-14_000000.log
```

Options

This section describes pgbadger command-line options.

```
-a minutes
--average minutes
```

Specifies the number of minutes for which to build average graphs of queries and connections.

Default: 5.

`-A minutes`

`--histo-average minutes`

Specifies the number of minutes for which to build histogram graphs of queries.

Default: 60.

`-b datetime`

`--begin datetime`

Specifies the start date/time for the data to be parsed in logs.

`-c host`

`--dbclient host`

Only report on log entries for the specified client host.

`-C`

`--nocomment`

Remove `/* ... */` comments from queries.

`-d name`

`--dbname name`

Only report on log entries for the specified database.

`-D`

`--dns-resolv`

Replace client IP addresses with their DNS names.

Warning

This can considerably slow down pgbadger.

`-e datetime`

`--end datetime`

Specifies the end date/time for the data to be parsed in logs.

`-E`

`--explode`

Build one report per each database. Global information not related to any database gets added to the `postgres` database report.

`-f logtype`

`--format logtype`

Specifies the log type.

Possible values: `syslog`, `syslog2`, `stderr`, `jsonlog`, `csv`, `pgbouncer`, `logplex`, `rds` and `redshift`. Use when pgbadger cannot detect the log format.

`-G`

`--nograph`

Disables graphs in HTML output.

`-h`

`--help`

Show detailed information about pbadger options and exit.

`-H path`

`--html-outdir path`

Specifies the path to the directory where the HTML report must be written in the incremental mode. Note that binary files remain in the directory specified by `-O/--outdir`.

`-i name`

`--ident name`

Specifies the program name used to identify Postgres Pro messages in syslog logs.

Default: postgres.

`-I`

`--incremental`

Use the incremental mode, where reports will be generated by days in a separate directory specified by the `-O/--outdir` option.

`-j number`

`--jobs number`

Specifies the number of jobs to run at same time. When working with csvlog logs, pgbadger always runs as single job.

Default: 1.

`-J number`

`--Jobs number`

Specifies the number of log files to parse in parallel. When working with csvlog logs, one log at a time is processed.

Default: 1.

`-l filename`

`--last-parsed filename`

Specifies the file where the last datetime and line parsed are registered to allow incremental log parsing. Useful to watch errors since the last run or to get one report per day with the log rotated weekly.

`-L filename`

`--logfile-list filename`

Specifies the file containing the list of log files to parse.

`-m size`

`--maxlength size`

Specifies the maximum length of a query in reports. Longer queries will be truncated.

Default: 100000.

`-M`

`--no-multiline`

Turns off collecting multiline statements to avoid reporting excessive information, especially on errors that generate a huge report.

`-N name`

`--appname name`

Only report on log entries for the specified application.

`-o filename`
`--outfile filename`

Specifies the filename for the output and determines the report file format. Can be used multiple times to output several formats. For the `json` output, ensure that the Perl module `JSON::XS` is installed. To dump the output to stdout, use the value of `"-"` as filename.

Default: `out.html`, `out.txt`, `out.bin`, `out.json` or `out.tsung`,
for the respective output format.

`-O path`
`--outdir path`

Specifies the directory where the out file must be saved.

`-p string`
`--prefix string`

Specifies the value of your custom `log_line_prefix` string, as defined in your `postgresql.conf`. Only use if your log line prefix is different from [the standard log_line_prefix strings](#), for example, if your prefix includes additional variables, such as client IP or application name.

`-P`
`--no-prettify`

Disables SQL query code prettifier.

`-q`
`--quiet`

Disables printing anything to stdout, even the progress bar.

`-Q`
`--query-numbering`

Add numbering of queries to the output when used together with `--dump-all-queries` or `--normalized-only`.

`-r address`
`--remote-host address`

Specifies the host to execute the `cat` command on a remote log file to parse the file locally.

`-R number`
`--retention number`

Specifies the number of weeks for which to keep reports in the output directory in the incremental mode. The directories for older weeks and days are automatically removed.

Default: 0 (no reports are removed).

`-s number`
`--sample number`

Specifies the number of query samples to store.

Default: 3.

`-S`
`--select-only`

Only report on SELECT queries.

`-t number`

`--top number`

Specifies the number of queries to store/display.

Default: 20.

`-T string`

`--title string`

Specifies the title of the HTML report page.

`-u username`

`--dbuser username`

Only report on log entries for the specified username.

`-U username`

`--exclude-user username`

Specifies the username to exclude log entries for from the report. Can be used multiple times.

`-v`

`--verbose`

Enables the verbose or debug mode.

Default: off.

`-V`

`--version`

Show pgbadger version and exit.

`-w`

`--watch-mode`

Only report errors, just like [Logwatch](#) can do.

`-W`

`--wide-char`

Encode HTML output of queries in UTF8 to avoid Perl messages “Wide character in print”.

`-x format`

`--extension format`

Specifies the output format. Possible values: text, html, bin, json or tsung.

Default: html.

`-X`

`--extra-files`

In the incremental mode, write CSS and JavaScript resources to the output directory as separate files.

`-z command`

`--zcat command`

Specifies the full command to run the zcat program. Use if zcat, bzip or unzip is outside of your PATH directories.

`-Z +/-XX`

`--timezone +/-XX`

Specifies the number of hours from GMT for the timezone. Use to adjust date/time in JavaScript graphs.

`--pie-limit number`

Specifies the number such that instead of lower pie data the sum will be shown.

`--exclude-query regex`

Specifies the regular expression such that matching queries will be excluded from the report. For example: “`^(VACUUM|COMMIT)`”. Can be used multiple times.

`--exclude-file filename`

Specifies the path to the file that contains regular expressions to use to exclude matching queries from the report, one expression per line.

`--include-query regex`

Specifies the regular expression such that only matching queries will be included in the report. Can be used multiple times. For example: “`(tbl1|tbl2)`”.

`--include-file filename`

Specifies the path to the file that contains regular expressions to use to include matching queries in the report, one expression per line.

`--disable-error`

Turns off generation of an error report.

`--disable-hourly`

Turns off generation of an hourly report.

`--disable-type`

Turns off generation of a report on queries by type, database and user.

`--disable-query`

Turns off generation of query reports, such as slowest or most frequent queries, queries by users, by database and so on.

`--disable-session`

Turns off generation of a session report.

`--disable-connection`

Turns off generation of a connection report.

`--disable-lock`

Turns off generation of a lock report.

`--disable-temporary`

Turns off generation of a report on temporary files.

`--disable-checkpoint`

Turns off generation of checkpoint/restartpoint reports.

`--disable-autovacuum`

Turns off generation of an autovacuum report.

`--charset name`

Specifies the HTML charset to be used.

Default: utf-8.

`--csv-separator char`

Specifies the CSV field separator.

Default: “,”.

`--exclude-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be excluded from the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--include-time regexp`

Specifies the regular expression such that log entries for any matching timestamp will be included in the report. For example: “2013-04-12 .*”. Can be used multiple times.

`--exclude-db name`

Specifies the name of the database to exclude related log entries from the report. For example: “outdated_db”. Can be used multiple times.

`--exclude-appname name`

Specifies the name of the application to exclude related log entries from the report. For example: “pg_dump”. Can be used multiple time.

`--exclude-line regexp`

Specifies the regular expression such that any matching log entry will be excluded from the report. Can be used multiple times.

`--exclude-client address`

Specifies the client IP/name to exclude related log entries from the report. Can be used multiple times.

`--anonymize`

Obscure all literals in queries. Useful to hide confidential data.

`--noreport`

Prevents generation of reports in the incremental mode.

`--log-duration`

Associate log entries generated by `log_duration = on` and `log_statement = all`.

`--enable-checksum`

Add the MD5 sum under each query report.

`--journalctl command`

Specifies the command to produce the information similar to what the Postgres Pro log file contains. Usually, like this: `journalctl -u postgrespro-ent-13`.

`--pid-dir path`

Specifies the path to store the PID file.

Default: /tmp.

`--pid-file filename`

Specifies the name of the PID file to manage concurrent execution of pgbadger.

Default: `pgbadger.pid`.

`--rebuild`

Rebuild all HTML reports in incremental output directories that contain binary data files.

`--pgbouncer-only`

Only show **pgbouncer**-related menu in the header.

`--start-monday`

In the incremental mode, start calendar weeks on Monday. By default, they start on Sunday.

`--iso-week-number`

In the incremental mode, start calendar weeks on Monday with ISO 8601 week numbering: 01 to 53, where week 1 is the first week of a year that has at least 4 days.

`--normalized-only`

Only dump all normalized queries to `out.txt`.

`--log-timezone +/-XX`

Specifies the number of hours from GMT for the timezone to adjust date/time read from the log file before parsing. The use of this option makes log search with date/time more complicated.

`--prettify-json`

Prettify JSON output.

`--month-report YYYY-MM`

Specifies the month (YYYY-MM) to create a cumulative HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--day-report YYYY-MM-DD`

Specifies the day (YYYY-MM-DD) to create an HTML report for. Requires incremental output directories to be set and all the necessary binary data files available.

`--noexplain`

Avoid processing log lines generated by **auto_explain**.

`--command cmd`

Specifies the command to run to retrieve log entries on stdin. pgbadger will open a pipe to this command and parse log entries that it generates.

`--no-week`

Avoid building weekly reports in the incremental mode. Use if building weekly reports takes too long.

`--explain-url URL`

Specifies the URL to override the URL of the graphical explain tool.

Default: `http://explain.depesz.com/?is\_public=0&is\_anon=0&plan=`

`--tempdir path`

Specifies the directory for temporary files.

Default: `File::Spec->tmpdir() || '/tmp'`.

`--no-process-info`

Disables changing the pgbadger process title to help identify this process. Useful for systems where changing process titles is not supported.

`--dump-all-queries`

Dump all queries found in the log file to a text file, replacing bind parameters in the queries at their respective placeholder positions.

`--keep-comments`

Retains comments in normalized queries. Useful to distinguish between same normalized queries.

`--no-progressbar`

Disables displaying the progress bar.

Remote Log Connection Options

pgbadger can parse a remote log file fetched using passwordless SSH connection. Use the `-r/--remote-host` option to set the IP address or name of the target host. More options to define SSH connection parameters are as follows:

`--ssh-program ssh`

Specifies the path to the SSH program to use.

Default: `ssh`.

`--ssh-port port`

Specifies the SSH port for the connection.

Default: `22`.

`--ssh-user username`

Specifies the username for the connection.

Default: user running pgbadger.

`--ssh-identity filename`

Specifies the path to the identity file.

`--ssh-timeout seconds`

Specifies the timeout in seconds in case of the SSH connection failure.

Default: `10`.

`--ssh-option options`

Specifies the list of options to define SSH connection parameters. The following options are always used:

`-o ConnectTimeout=$ssh_timeout -o PreferredAuthentications=hostbased,publickey`

`-o PreferredAuthentications=hostbased,publickey`

```

Description

pg_probackup is a utility to manage backup and recovery of Postgres Pro database clusters. It is designed to perform periodic backups of the Postgres Pro instance that enable you to restore the server in case of a failure. pg_probackup supports PostgreSQL 11 or higher. In Postgres Pro Enterprise, pg_probackup provides S3 (Simple Storage Service) support for storing data in private clouds.

Note

pg_probackup provides complete processing of S3 interface logging.

- [Overview](#)
- [Quick Start](#)
- [Installation and Setup](#)
- [Command-Line Reference](#)
- [Usage](#)

Overview

As compared to other backup solutions, `pg_probackup` offers the following benefits that can help you implement different backup strategies and deal with large amounts of data:

- S3 support for storing data in private clouds using MinIO object storage, Amazon S3 storage, and VK Cloud storage: provided in Postgres Pro Enterprise. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.
- Incremental backup: with three different incremental modes, you can plan the backup strategy in accordance with your data flow. Incremental backups allow you to save disk space and speed up backup as compared to taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files.
- Incremental restore: speed up restore from backup by reusing valid unchanged pages available in PGDATA.
- CFS (Compressed File System) support for incremental backups in [DELTA](#), [PAGE](#), and [PTRACK](#) (the fastest) modes: provided in Postgres Pro Enterprise.
- Validation: automatic data consistency checks and on-demand backup validation without actual data recovery.
- Verification: on-demand verification of Postgres Pro instance with the `checkdb` command.
- Retention: managing WAL archive and backups in accordance with retention policy. You can configure retention policy based on recovery time or the number of backups to keep, as well as specify time to live (TTL) for a particular backup. Expired backups can be merged or deleted.
- Parallelization: running `backup`, `restore`, `merge`, `delete`, `validate`, and `checkdb` processes on multiple parallel threads.
- Compression: storing backup data in a compressed state to save disk space.
- Deduplication: saving disk space by excluding non-data files (such as `_vm` or `_fsm`) from incremental backups if these files have not changed since they were copied into one of the previous backups in this incremental chain.
- Remote operations: backing up Postgres Pro instance located on a remote system or restoring a backup remotely.
- Backup from standby: avoiding extra load on master by taking backups from a standby server.
- External directories: backing up files and directories located outside of the Postgres Pro data directory (`PGDATA`), such as scripts, configuration files, logs, or SQL dump files.
- Backup catalog: getting the list of backups and the corresponding meta information in plain text or JSON formats.
- Archive catalog: getting the list of all WAL timelines and the corresponding meta information in plain text or JSON formats.
- Partial restore: restoring only the specified databases.
- Catchup: cloning a Postgres Pro instance for a fallen-behind standby server to “catch up” with master.

To manage backup data, `pg_probackup` creates a *backup catalog*. This is a directory that stores all backup files with additional meta information, as well as WAL archives required for point-in-time recovery. You can store backups for different instances in separate subdirectories of a single backup catalog.

Using `pg_probackup`, you can take full or incremental [backups](#):

- FULL backups contain all the data files required to restore the database cluster.
- Incremental backups operate at the page level, only storing the data that has changed since the previous backup. It allows you to save disk space and speed up the backup process as compared to

taking full backups. It is also faster to restore the cluster by applying incremental backups than by replaying WAL files. `pg_probackup` supports the following modes of incremental backups:

- **DELTA backup.** In this mode, `pg_probackup` reads all data files in the data directory and copies only those pages that have changed since the previous backup. This mode can impose read-only I/O pressure equal to a full backup.
- **PAGE backup.** In this mode, `pg_probackup` scans all WAL files in the archive from the moment the previous full or incremental backup was taken. Newly created backups contain only the pages that were mentioned in WAL records. This requires all the WAL files since the previous backup to be present in the WAL archive. If the size of these files is comparable to the total size of the database cluster files, speedup is smaller, but the backup still takes less space. You have to configure WAL archiving as explained in [Setting up continuous WAL archiving](#) to make PAGE backups.
- **PTRACK backup.** In this mode, Postgres Pro tracks page changes on the fly. Continuous archiving is not necessary for it to operate. Each time a relation page is updated, this page is marked in a special PTRACK bitmap. Tracking implies some minor overhead on the database server operation, but speeds up incremental backups significantly.

`pg_probackup` can take only physical online backups, and online backups require WAL for consistent recovery. So regardless of the chosen backup mode (FULL, PAGE or DELTA), any backup taken with `pg_probackup` must use one of the following *WAL delivery modes*:

- **ARCHIVE.** Such backups rely on [continuous archiving](#) to ensure consistent recovery. This is the default WAL delivery mode.
- **STREAM.** Such backups include all the files required to restore the cluster to a consistent state at the time the backup was taken. Regardless of [continuous archiving](#) having been set up or not, the WAL segments required for consistent recovery are streamed via replication protocol during backup and included into the backup files. That's why such backups are called *autonomous*, or *stand-alone*.

Limitations

`pg_probackup` currently has the following limitations:

- The remote mode is not supported on Windows systems.
- On Unix systems, for Postgres Pro 11, a backup can be made only by the same OS user that has started the Postgres Pro server. For example, if Postgres Pro server is started by user `postgres`, the `backup` command must also be run by user `postgres`. To satisfy this requirement when taking backups in the [remote mode](#) using SSH, you must set `--remote-user` option to `postgres`.
- The Postgres Pro server from which the backup was taken and the restored server must be compatible by the [block_size](#) and [wal_block_size](#) parameters and have the same major release number. Depending on cluster configuration, Postgres Pro itself may apply additional restrictions, such as CPU architecture or `libc/icu` versions.
- Special limitations of `pg_probackup` in Postgres Pro Enterprise:
 - S3 interface is provided for private cloud solutions. In this version, you cannot run [merge](#) command using S3 interface and [backup](#) and [delete](#) commands do not support `--merge-expired` flag yet.
 - Incremental backup and restore for CFS tablespaces require `ptrack 2.4.0` or higher.
 - Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [delete](#), [archive-push](#), and [archive-get](#).

Quick Start

To quickly get started with `pg_probackup`, complete the steps below. This will set up FULL and DELTA backups in the remote mode and demonstrate some basic `pg_probackup` operations. In the following, these terms are used:

- `backup` — Postgres Pro role used to connect to the Postgres Pro cluster.

- `backupdb` — database used to connect to the Postgres Pro cluster.
- `backup_host` — host with the backup catalog.
- `backup_user` — user on `backup_host` running all `pg_probackup` operations.
- `/mnt/backups` — directory on `backup_host` where the backup catalog is stored.
- `postgres_host` — host with the Postgres Pro cluster.
- `postgres` — user on `postgres_host` under which Postgres Pro cluster processes are running.
- `/var/lib/pgpro/std-16/data` — Postgres Pro data directory on `postgres_host`.

Steps to perform:

1. Install `pg_probackup` on both `backup_host` and `postgres_host`.
2. [Set up an SSH connection](#) from `backup_host` to `postgres_host`.
3. [Configure](#) your database cluster for [STREAM backups](#).
4. Initialize the backup catalog:

```
[backup_user@backup_host]$ pg_probackup init -B /mnt/backups
INFO: Backup catalog '/mnt/backups' successfully initialized
```

5. Add a backup instance called `mydb` to the backup catalog:

```
[backup_user@backup_host]$ pg_probackup add-instance \
-B /mnt/backups \
-D /var/lib/pgpro/std-16/data \
--instance=mydb \
--remote-host=postgres_host \
--remote-user=postgres
INFO: Instance 'mydb' successfully initialized
```

6. Make a FULL backup:

```
[backup_user@backup_host] pg_probackup backup \
-B /mnt/backups \
-b FULL \
--instance=mydb \
--stream \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
```

```
INFO: Backup start, pg_probackup version: 2.7.0, instance: mydb, backup ID: S6674L,
backup mode: FULL, wal mode: STREAM, remote: true, compress-algorithm: none,
compress-level: 1
```

```
INFO: This PostgreSQL instance was initialized with data block checksums. Data
block corruption will be detected
```

```
INFO: Database backup start
```

```
INFO: wait for pg_backup_start()
```

```
INFO: PGDATA size: 30MB
```

```
INFO: Current Start LSN: 0/2000028, TLI: 1
```

```
INFO: Start transferring data files
```

```
INFO: Data files are transferred, time elapsed: 0
```

```
INFO: wait for pg_stop_backup()
```

```
INFO: pg_stop_backup() successfully executed
```

```
INFO: stop_stream_lsn 0/3000000 currentpos 0/3000000
```

```
INFO: backup->stop_lsn 0/200F8B0
```

```
INFO: Getting the Recovery Time from WAL
```

```
INFO: Syncing backup files to disk
```

```
INFO: Backup files are synced, time elapsed: 1s
```

```
INFO: Validating backup S6674L
INFO: Backup S6674L data files are valid
INFO: Backup S6674L resident size: 46MB
INFO: Backup S6674L completed
```

7. List the backups of the instance:

```
[backup_user@backup_host] pg_probackup show -B /mnt/backups --instance=mydb
```

```
=====
Instance Version ID      Recovery Time      Mode WAL Mode  TLI
Time Data   WAL  Zalg  Zratio Start LSN  Stop LSN  Status
=====
mydb      16      S6674L 2023-12-24 12:09:57.799492+00 FULL  STREAM    1/0
1s 30MB 16MB none  1.00 0/2000028 0/200F8B0 OK
=====
```

8. Make an incremental backup in the DELTA mode:

```
[backup_user@backup_host] pg_probackup backup \
-B /mnt/backups \
-b delta \
--instance=mydb \
--stream \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
-d backupdb
```

```
INFO: Backup start, pg_probackup version: 2.7.0, instance: mydb, backup ID: S667BR,
backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
compress-level: 1
INFO: This PostgreSQL instance was initialized with data block checksums. Data
block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: S6674L
INFO: PGDATA size: 30MB
INFO: Current Start LSN: 0/4000028, TLI: 1
INFO: Parent Start LSN: 0/2000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 1s
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/5000000 currentpos 0/5000000
INFO: backup->stop_lsn 0/4000170
INFO: Getting the Recovery Time from WAL
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup S667BR
INFO: Backup S667BR data files are valid
INFO: Backup S667BR resident size: 16MB
INFO: Backup S667BR completed
```

9. Add or modify some parameters in the pg_probackup configuration file, so that you do not have to specify them each time on the command line:

```
[backup_user@backup_host] pg_probackup set-config \
-B /mnt/backups \
--instance=mydb \
--remote-host=postgres_host \
--remote-user=postgres \
-U backup \
```

-d backupdb

10. Check the configuration of the instance:

```
[backup_user@backup_host] pg_probackup show-config -B /mnt/backups --instance=mydb
# Backup instance information
pgdata = /var/lib/pgpro/std-16/data
system-identifier = 7316129607401733083
xlog-seg-size = 16777216
# Connection parameters
pgdatabase = backupdb
pghost = postgres_host
pguser = backup
# Archive parameters
archive-timeout = 5min
# Logging parameters
log-level-console = INFO
log-level-file = OFF
log-format-console = PLAIN
log-format-file = PLAIN
log-filename = pg_probackup.log
log-rotation-size = 0TB
log-rotation-age = 0d
# Retention parameters
retention-redundancy = 0
retention-window = 0
wal-depth = 0
# Compression parameters
compress-algorithm = none
compress-level = 1
# Remote access parameters
remote-proto = ssh
remote-host = postgres_host
remote-user = postgres
```

Note that the parameters not modified via `set-config` retain their default values.

11. Make another incremental backup in the DELTA mode, omitting the parameters stored in the configuration file earlier:

```
[backup_user@backup_host] pg_probackup backup -B /mnt/backups --instance=mydb -b
delta --stream
INFO: Backup start, pg_probackup version: 2.7.0, instance: mydb, backup ID: S667F1,
      backup mode: DELTA, wal mode: STREAM, remote: true, compress-algorithm: none,
      compress-level: 1
INFO: This PostgreSQL instance was initialized with data block checksums. Data
      block corruption will be detected
INFO: Database backup start
INFO: wait for pg_backup_start()
INFO: Parent backup: S667BR
INFO: PGDATA size: 30MB
INFO: Current Start LSN: 0/6000028, TLI: 1
INFO: Parent Start LSN: 0/4000028, TLI: 1
INFO: Start transferring data files
INFO: Data files are transferred, time elapsed: 0
INFO: wait for pg_stop_backup()
INFO: pg_stop_backup() successfully executed
INFO: stop_stream_lsn 0/7000000 currentpos 0/7000000
INFO: backup->stop_lsn 0/6000170
INFO: Getting the Recovery Time from WAL
```

```
INFO: Syncing backup files to disk
INFO: Backup files are synced, time elapsed: 0
INFO: Validating backup S667F1
INFO: Backup S667F1 data files are valid
INFO: Backup S667F1 resident size: 16MB
INFO: Backup S667F1 completed
```

12. List the backups of the instance again:

```
[backup_user@backup_host] pg_probackup show -B /mnt/backups --instance=mydb
```

```
=====
Instance  Version  ID          Recovery Time          Mode  WAL Mode  TLI
Time      Data    WAL  Zalg  Zratio  Start LSN  Stop LSN  Status
=====
mydb      16      S667F1  2023-12-24 12:16:13.972949+00  DELTA  STREAM    1/1
1s 119kB 16MB none    1.00  0/6000028  0/6000170  OK

1s 30MB 16MB none    1.00  0/2000028  0/200F8B0  OK
=====
```

13. Restore the data from the latest available backup to an arbitrary location:

```
[backup_user@backup_host] pg_probackup restore -B /mnt/backups -D /var/lib/pgpro/
std-16/staging-data --instance=mydb
INFO: Validating parents for backup S667F1
INFO: Validating backup S6674L
INFO: Backup S6674L data files are valid
INFO: Validating backup S667BR
INFO: Backup S667BR data files are valid
INFO: Validating backup S667F1
INFO: Backup S667F1 data files are valid

```

Installation and Setup

Once you have `pg_probackup` installed, complete the following setup:

- Initialize the backup catalog.
- Add a new backup instance to the backup catalog.
- Configure the database cluster to enable `pg_probackup` backups.
- Optionally, configure SSH for running `pg_probackup` operations in the remote mode.
- Optionally, configure S3 for running `pg_probackup` connected to the S3 storage.

Initializing the Backup Catalog

`pg_probackup` stores all WAL and backup files in the corresponding subdirectories of the backup catalog.

To initialize the backup catalog, run the following command:

```
pg_probackup init -B backup_dir
```

where *backup_dir* is the path to the backup catalog. If the *backup_dir* already exists, it must be empty. Otherwise, `pg_probackup` returns an error.

The user launching `pg_probackup` must have full access to the `backup_dir` directory.

`pg_probackup` creates the `backup_dir` backup catalog, with the following subdirectories:

- `wal/` — directory for WAL files.
- `backups/` — directory for backup files.

Once the backup catalog is initialized, you can add a new backup instance.

Adding a New Backup Instance

`pg_probackup` can store backups for multiple database clusters in a single backup catalog. To set up the required subdirectories, you must add a backup instance to the backup catalog for each database cluster you are going to back up.

To add a new backup instance, run the following command:

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name
[remote_options]
```

Where:

- `data_dir` is the data directory of the cluster you are going to back up. To set up and use `pg_probackup`, write access to this directory is required.
- `instance_name` is the name of the subdirectories that will store WAL and backup files for this cluster.
- [remote_options](#) are optional parameters that need to be specified only if `data_dir` is located on a remote system.

`pg_probackup` creates the `instance_name` subdirectories under the `backups/` and `wal/` directories of the backup catalog. The `backups/instance_name` directory contains the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for this backup instance. If you run this command with the [remote_options](#), the specified parameters will be added to `pg_probackup.conf`.

For details on how to fine-tune `pg_probackup` configuration, see [the section called “Configuring pg_probackup”](#).

The user launching `pg_probackup` must have full access to `backup_dir` directory and at least read-only access to `data_dir` directory. If you specify the path to the backup catalog in the `BACKUP_PATH` environment variable, you can omit the corresponding option when running `pg_probackup` commands.

Note

For Postgres Pro 11 or higher, it is recommended to use the [group access](#) feature, so that backup can be done by any OS user in the same group as the cluster owner. In this case, the user should have read permissions for the cluster directory.

Configuring the Database Cluster

Although `pg_probackup` can be used by a superuser, it is recommended to create a separate role with the minimum permissions required for the chosen backup strategy. In these configuration instructions, the `backup` role is used as an example.

For security reasons, it is recommended to run the configuration SQL queries below in a separate database.

```
postgres=# CREATE DATABASE backupdb;
postgres=# \c backupdb
```

To perform a [backup](#), the following permissions for role `backup` are required only in the database **used for connection** to the Postgres Pro server.

For Postgres Pro versions 11 — 14:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_start_backup(text, boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_stop_backup(boolean, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

For Postgres Pro 15 or higher:

```
BEGIN;
CREATE ROLE backup WITH LOGIN;
GRANT USAGE ON SCHEMA pg_catalog TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.current_setting(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.set_config(text, text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_is_in_recovery() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_start(text, boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_backup_stop(boolean) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_create_restore_point(text) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_switch_wal() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_last_wal_replay_lsn() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_current_snapshot() TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.txid_snapshot_xmax(txid_snapshot) TO backup;
GRANT EXECUTE ON FUNCTION pg_catalog.pg_control_checkpoint() TO backup;
COMMIT;
```

In the [pg_hba.conf](#) file, allow connection to the database cluster on behalf of the `backup` role.

Since `pg_probackup` needs to read cluster files directly, `pg_probackup` must be started by (or connected to, if used in the remote mode) the OS user that has read access to all files and directories inside the data directory (`PGDATA`) you are going to back up.

Depending on whether you plan to take [standalone](#) or [archive](#) backups, Postgres Pro cluster configuration will differ, as specified in the sections below. To back up the database cluster from a standby server, run `pg_probackup` in the remote mode, or create PTRACK backups, additional setup is required.

For details, see the sections [Setting up STREAM Backups](#), [Setting up continuous WAL archiving](#), [Setting up Backup from Standby](#), [Configuring the Remote Mode](#), [Setting up Partial Restore](#), and [Setting up PTRACK Backups](#).

Setting up STREAM Backups

To set up the cluster for [STREAM](#) backups, complete the following steps:

- If the `backup` role does not exist, create it with the `REPLICATION` privilege when [Configuring the Database Cluster](#):

```
CREATE ROLE backup WITH LOGIN REPLICATION;
```

- If the `backup` role already exists, grant it with the `REPLICATION` privilege:

```
ALTER ROLE backup WITH REPLICATION;
```

- In the `pg_hba.conf` file, allow replication on behalf of the `backup` role.
- Make sure the parameter `max_wal_senders` is set high enough to leave at least one session available for the backup process.
- Set the parameter `wal_level` to be higher than `minimal`.

If you are planning to take PAGE backups in the STREAM mode or perform PITR with STREAM backups, you still have to configure WAL archiving, as explained in the section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, and PTRACK backups in the **STREAM** WAL mode.

Note

If you are planning to rely on `.pgpass` for authentication when running backup in STREAM mode, then `.pgpass` must contain credentials for `replication` database, used to establish connection via replication protocol. Example: `pghost:5432:replication:backup_user:my_strong_password`

Setting up Continuous WAL Archiving

Making backups in PAGE backup mode, performing [PITR](#) and making backups with **ARCHIVE** WAL delivery mode require [continuous WAL archiving](#) to be enabled. To set up continuous archiving in the cluster, complete the following steps:

- Make sure the `wal_level` parameter is higher than `minimal`.
- If you are configuring archiving on master, `archive_mode` must be set to `on` or `always`. To perform archiving on standby, set this parameter to `always`.
- Set the `archive_command` parameter, as follows:

```
archive_command = '"install_dir/pg_probackup" archive-push -B "backup_dir" --  
instance instance_name --wal-file-name=%f [remote_options]'
```

where `install_dir` is the installation directory of the `pg_probackup` version you are going to use, `backup_dir` and `instance_name` refer to the already initialized backup catalog instance for this database cluster, and `remote_options` only need to be specified to archive WAL on a remote host. For details about all possible `archive-push` parameters, see the section [archive-push](#).

Once these steps are complete, you can start making backups in the **ARCHIVE** WAL mode, backups in the PAGE backup mode, as well as perform [PITR](#).

You can view the current state of the WAL archive using the `show` command. For details, see [the section called “Viewing WAL Archive Information”](#).

If you are planning to make PAGE backups and/or backups with **ARCHIVE** WAL mode from a standby server that generates a small amount of WAL traffic, without long waiting for WAL segment to fill up, consider setting the `archive_timeout` Postgres Pro parameter **on master**. The value of this parameter should be slightly lower than the `--archive-timeout` setting (5 minutes by default), so that there is enough time for the rotated segment to be streamed to standby and sent to WAL archive before the backup is aborted because of `--archive-timeout`.

Note

Instead of using the `archive-push` command provided by `pg_probackup`, you can use any other tool to set up continuous archiving as long as it delivers WAL segments into `backup_dir/wal/in-`

`stance_name` directory. If compression is used, it should be `gzip`, and `.gz` suffix in filename is mandatory.

Note

Instead of configuring continuous archiving by setting the `archive_mode` and `archive_command` parameters, you can opt for using the [pg_receivewal](#) utility. In this case, `pg_receivewal -D directory` option should point to `backup_dir/wal/instance_name` directory. `pg_probackup` supports WAL compression that can be done by `pg_receivewal`. “Zero Data Loss” archive strategy can be achieved only by using `pg_receivewal`.

Setting up Backup from Standby

`pg_probackup` can take backups from a standby server. This requires the following additional setup:

- On the standby server, set the [hot_standby](#) parameter to `on`.
- On the master server, set the [full_page_writes](#) parameter to `on`.
- To perform standalone backups on standby, complete all steps in section [Setting up STREAM Backups](#).
- To perform archive backups on standby, complete all steps in section [Setting up continuous WAL archiving](#).

Once these steps are complete, you can start taking FULL, PAGE, DELTA, or PTRACK backups with appropriate WAL delivery mode: ARCHIVE or STREAM, from the standby server.

Backup from the standby server has the following limitations:

- If the standby is promoted to the master during backup, the backup fails.
- All WAL records required for the backup must contain sufficient full-page writes. This requires you to enable `full_page_writes` on the master, and not to use tools like `pg_compresslog` as [archive_command](#) to remove full-page writes from WAL files.

Setting up Cluster Verification

Logical verification of a database cluster requires the following additional setup. Role `backup` is used as an example:

- Install the [amcheck](#) or [amcheck_next](#) extension **in every database** of the cluster:

```
CREATE EXTENSION amcheck;
```

- Grant the following permissions to the `backup` role **in every database** of the cluster:

```
GRANT SELECT ON TABLE pg_catalog.pg_am TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_class TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_namespace TO backup;
GRANT SELECT ON TABLE pg_catalog.pg_extension TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool) TO backup;
GRANT EXECUTE ON FUNCTION bt_index_check(regclass, bool, bool) TO backup;
```

Setting up Partial Restore

If you are planning to use partial restore, complete the following additional step:

- Grant the read-only access to `pg_catalog.pg_database` to the `backup` role only in the database **used for connection** to Postgres Pro server:

```
GRANT SELECT ON TABLE pg_catalog.pg_database TO backup;
```

Configuring the Remote Mode

`pg_probackup` supports the remote mode that allows you to perform backup, restore and WAL archiving operations remotely. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to backup and/or to restore is located on a remote system. Currently the only supported remote protocol is SSH.

Set up SSH

If you are going to use `pg_probackup` in remote mode via SSH, complete the following steps:

1. Install `pg_probackup` on both systems: `backup_host` and `postgres_host`.
2. For communication between the hosts set up a passwordless SSH connection between the `backup_user` user on `backup_host` and the `postgres` user on `postgres_host`:

```
[backup_user@backup_host] ssh-copy-id postgres@postgres_host
```

Where:

- `backup_host` is the system with *backup catalog*.
 - `postgres_host` is the system with the Postgres Pro cluster.
 - `backup_user` is the OS user on `backup_host` used to run `pg_probackup`.
 - `postgres` is the user on `postgres_host` under which Postgres Pro cluster processes are running. For Postgres Pro 11 or higher a more secure approach can be used thanks to [group access](#) feature.
3. If you are going to rely on [continuous WAL archiving](#), set up a passwordless SSH connection between the `postgres` user on `postgres_host` and the `backup` user on `backup_host`:

```
[postgres@postgres_host] ssh-copy-id backup_user@backup_host
```

4. Make sure `pg_probackup` on `postgres_host` can be located when a connection via SSH is made. For example, for Bash, you can modify `PATH` in `~/.bashrc` of the `postgres` user (above the line in `bashrc` that exits the script for non-interactive shells). Alternatively, for `pg_probackup` commands, specify the path to the directory containing the `pg_probackup` binary on `postgres_host` via the [--remote-path](#) option.

`pg_probackup` in the remote mode via SSH works as follows:

- Only the following commands can be launched in the remote mode: [add-instance](#), [backup](#), [restore](#), [catchup](#), [archive-push](#), and [archive-get](#).
- Operating in remote mode requires `pg_probackup` binary to be installed on both local and remote systems. The versions of local and remote binary must be the same.
- When started in the remote mode, the main `pg_probackup` process on the local system connects to the remote system via SSH and launches one or more agent processes on the remote system, which are called *remote agents*. The number of remote agents is equal to the `-j/--threads` setting.
- The main `pg_probackup` process uses remote agents to access remote files and transfer data between local and remote systems.
- Remote agents try to minimize the network traffic and the number of round-trips between hosts.
- The main process is usually started on `backup_host` and connects to `postgres_host`, but in case of `archive-push` and `archive-get` commands the main process is started on `postgres_host` and connects to `backup_host`.
- Once data transfer is complete, remote agents are terminated and SSH connections are closed.
- If an error condition is encountered by a remote agent, then all agents are terminated and error details are reported by the main `pg_probackup` process, which exits with an error.
- Compression is always done on `postgres_host`, while decompression is always done on `backup_host`.

Note

You can impose [additional restrictions](#) on SSH settings to protect the system in the event of account compromise.

Note

Setting the number of threads (`-j/--threads` option) to a value greater than 10 for `pg_probackup` working in the remote mode via SSH may result in the actual number of SSH connections exceeding the maximum allowed number of simultaneous SSH connections on the remote server and consequently lead to an “ERROR: Agent error: kex_exchange_identification: Connection closed by remote host” error. To correct the error, either reduce the number of `pg_probackup` threads or adjust the value of `MaxStartups` configuration parameter of the remote SSH server. If SSH is set up as a `xinetd` service on the remote server, adjust the value of the `xinetd` `per_source` configuration parameter rather than `MaxStartups`.

Configuring S3 Connectivity

`pg_probackup` supports S3 interface for storing backups. Backup data is transferred to and from S3 without saving it in intermediate locations thus eliminating the need of having a large temporary storage.

An example configuration with a remote agent and a cloud storage (S3) is shown in [Figure G.1](#).

Figure G.1. `pg_probackup` setup with a remote agent and S3

In this figure, the following logical components are shown:

Backup server

A server where the main process of `pg_probackup` runs and where local backups are stored.

Database server

A server with a database instance that needs to be backed up or restored.

Remote agent

A secondary `pg_probackup` process running on the database server. Only applicable to the remote mode.

Cloud storage

A cloud storage for backups.

Set up Access to S3 Storage

If you are going to use `pg_probackup` with S3 interface, complete the following steps:

- Create a bucket with a unique and meaningful name in the S3 storage for you future backups.
- Create `ACCESS_KEY` and `SECRET_ACCESS_KEY` tokens to be used for secure connectivity instead of your username and password.
- For communication between `pg_probackup` and S3 server, set values of environment variables corresponding to your S3 server. For example:

```
export PG_PROBACKUP_S3_HOST=127.0.0.1
export PG_PROBACKUP_S3_PORT=9000
export PG_PROBACKUP_S3_REGION=ru-msk
export PG_PROBACKUP_S3_BUCKET_NAME=test1
export PG_PROBACKUP_S3_ACCESS_KEY=admin
export PG_PROBACKUP_S3_SECRET_ACCESS_KEY=password
export PG_PROBACKUP_S3_HTTPS=ON
```

Alternatively, you can provide S3 server settings in the S3 configuration file (see the `--s3-config-file` option in the section [S3 Options](#) for details).

It makes sense to specify S3 server settings if `--s3=minio`, as described in the section [S3 Options](#).

The following environment variables can be specified:

`PG_PROBACKUP_S3_HOST`

Address or list of addresses of the S3 server. A list of one or several semicolon-delimited addresses. Do not add a semicolon after the last address in the list. Each address can include the port number, separated by a colon. If the port number is not specified, the value of `PG_PROBACKUP_S3_PORT` is assumed. Do not add a colon if the port number is not specified.

For example:

```
export PG_PROBACKUP_S3_PORT=80
export PG_PROBACKUP_S3_HOST="127.0.0.1:9000;10.4.13.56:443;172.17.0.1"
```

In this example, for the “127.0.0.1” address, the port 9000 is explicitly specified, for “10.4.13.56”, the port 443 is specified, while for the “172.17.0.1” address, port 80, specified through `PG_PROBACKUP_S3_PORT`, will be used.

If any of the specified addresses gets unavailable while `pg_probackup` is in operation, requests to the S3 storage are distributed between the rest of the specified addresses. That is, when several addresses are specified, `pg_probackup` performs load balancing of S3 requests.

`PG_PROBACKUP_S3_PORT`

The port of the S3 server.

`PG_PROBACKUP_S3_REGION`

The region of the S3 server.

`PG_PROBACKUP_S3_BUCKET_NAME`

The name of the bucket on the S3 server.

`PG_PROBACKUP_S3_ACCESS_KEY`

`PG_PROBACKUP_S3_SECRET_ACCESS_KEY`

Secure tokens on the S3 server.

`PG_PROBACKUP_S3_HTTPS`

The protocol to be used. Possible values:

- `ON` or `HTTPS` — use `HTTPS`
- Other than `ON` or `HTTPS` — use `HTTP`

`PG_PROBACKUP_S3_BUFFER_SIZE`

The size of the read/write buffer for communicating with S3, in MiB. The default is 16.

`PG_PROBACKUP_S3_RETRIES`

The maximum number of attempts to execute an S3 request in case of failures. The default is 3.

`PG_PROBACKUP_S3_TIMEOUT`

The maximum amount of time to execute an HTTP request to the S3 server, in seconds. The default is 300.

`PG_PROBACKUP_S3_IGNORE_CERT_VER`

Don't verify the certificate host and peer. The default is `ON`.

`PG_PROBACKUP_S3_CA_CERTIFICATE`

Specify the path to file with trust Certificate Authority (CA) bundle.

`PG_PROBACKUP_S3_CA_PATH`

Specify the directory with trust CA certificates.

`PG_PROBACKUP_S3_CLIENT_CERT`

Setup SSL client certificate.

`PG_PROBACKUP_S3_CLIENT_KEY`

Setup private key file for TLS and SSL client certificate.

Setting up PTRACK Backups

Note

PTRACK versions lower than 2.0 are deprecated and not supported. Postgres Pro Standard and Postgres Pro Enterprise versions starting with 11.9.1 contain PTRACK 2.0. Upgrade your server to avoid issues in backups that you will take in future and be sure to take fresh backups of your clusters with the upgraded PTRACK since the backups taken with PTRACK 1.x might be corrupt.

If you are going to use PTRACK backups, complete the following additional steps. The role that will perform PTRACK backups (the `backup` role in the examples below) must have access to all the databases of the cluster.

For Postgres Pro 11 or higher:

1. Create PTRACK extension:

```
CREATE EXTENSION ptrack;
```

2. To enable tracking page updates, set `ptrack.map_size` parameter to a positive integer and restart the server.

For optimal performance, it is recommended to set `ptrack.map_size` to $N / 1024$, where N is the size of the Postgres Pro cluster, in MB. If you set this parameter to a lower value, PTRACK is more likely to map several blocks together, which leads to false-positive results when tracking changed blocks and increases the incremental backup size as unchanged blocks can also be copied into the

incremental backup. Setting `ptrack.map_size` to a higher value does not affect PTRACK operation, but it is not recommended to set this parameter to a value higher than 1024.

Note

If you change the `ptrack.map_size` parameter value, the previously created PTRACK map file is cleared, and tracking newly changed blocks starts from scratch. Thus, you have to retake a full backup before taking incremental PTRACK backups after changing `ptrack.map_size`.

Usage

Creating a Backup

To create a backup, run the following command:

```
pg_probackup backup -B backup_dir --instance instance_name -b backup_mode
```

Where `backup_mode` can take one of the following values: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

When restoring a cluster from an incremental backup, `pg_probackup` relies on the parent full backup and all the incremental backups between them, which is called “the backup chain”. Thus, to perform incremental backups, it is necessary to have the last parent full backup with the status `OK` or `DONE` in the directory. If the parent full backup has the `MERGING` or `MERGED` status, an incremental backup cannot be performed.

For example, if merge has already been launched with a single full backup, an attempt to perform an incremental backup will end with the following messages:

```
WARNING: Valid full backup on current timeline 1 is not found, trying to look up on
previous timelines
WARNING: Cannot find valid backup on previous timelines
ERROR: Create new full backup before an incremental one
```

ARCHIVE Mode

ARCHIVE is the default WAL delivery mode.

For example, to make a FULL backup in ARCHIVE mode, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL
```

ARCHIVE backups rely on [continuous archiving](#) to get WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

When a backup is taken, `pg_probackup` ensures that WAL files containing WAL records between `Start LSN` and `Stop LSN` actually exist in `backup_dir/wal/instance_name` directory. `pg_probackup` also ensures that WAL records between `Start LSN` and `Stop LSN` can be parsed. This precaution eliminates the risk of silent WAL corruption.

STREAM Mode

STREAM is the optional WAL delivery mode.

For example, to make a FULL backup in the STREAM mode, add the `--stream` flag to the command from the previous example:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --stream --temp-slot
```

The optional `--temp-slot` flag ensures that the required segments remain available if the WAL is rotated before the backup is complete.

Unlike backups in ARCHIVE mode, STREAM backups include all the WAL segments required to restore the cluster to a consistent state at the time the backup was taken.

During **backup** `pg_probackup` streams WAL files containing WAL records between `Start LSN` and `Stop LSN` to `backup_dir/backups/instance_name/backup_id/database/pg_wal` directory. To eliminate the risk of silent WAL corruption, `pg_probackup` also checks that WAL records between `Start LSN` and `Stop LSN` can be parsed.

Even if you are using **continuous archiving**, **STREAM** backups can still be useful in the following cases:

- **STREAM** backups can be restored on the server that has no file access to WAL archive.
- **STREAM** backups enable you to restore the cluster state at the point in time for which WAL files in archive are no longer available.
- Backup in **STREAM** mode can be taken from a standby of a server that generates small amount of WAL traffic, without long waiting for WAL segment to fill up.

Page Validation

If **data_checksums** are enabled in the database cluster, `pg_probackup` uses this information to check correctness of data files during backup. While reading each page, `pg_probackup` checks whether the calculated checksum coincides with the checksum stored in the page header. This guarantees that the Postgres Pro instance and the backup itself have no corrupt pages. Note that `pg_probackup` reads database files directly from the filesystem, so under heavy write load during backup it can show false-positive checksum mismatches because of partial writes. If a page checksum mismatch occurs, the page is re-read and checksum comparison is repeated.

A page is considered corrupt if checksum comparison has failed more than 300 times. In this case, the backup is aborted.

Even if data checksums are not enabled, `pg_probackup` always performs sanity checks for page headers.

External Directories

To back up a directory located outside of the data directory, use the optional `--external-dirs` parameter that specifies the path to this directory. If you would like to add more than one external directory, you can provide several paths separated by colons on Linux systems or semicolons on Windows systems.

For example, to include `/etc/dir1` and `/etc/dir2` directories into the full backup of your `instance_name` instance that will be stored under the `backup_dir` directory on Linux, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=/etc/dir1:/etc/dir2
```

Similarly, to include `C:\dir1` and `C:\dir2` directories into the full backup on Windows, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --external-dirs=C:\dir1;C:\dir2
```

`pg_probackup` recursively copies the contents of each external directory into a separate subdirectory in the backup catalog. Since external directories included into different backups do not have to be the same, when you are restoring the cluster from an incremental backup, only those directories that belong to this particular backup will be restored. Any external directories stored in the previous backups will be ignored.

To include the same directories into each backup of your instance, you can specify them in the `pg_probackup.conf` configuration file using the **set-config** command with the `--external-dirs` option.

Performing Cluster Verification

To verify that Postgres Pro database cluster is not corrupt, run the following command:

```
pg_probackup checkdb [-B backup_dir [--instance instance_name]] [-D data_dir] [connection_options]
```

This command performs physical verification of all data files located in the specified data directory by running page header sanity checks, as well as block-level checksum verification if checksums are

enabled. If a corrupt page is detected, `checkdb` continues cluster verification until all pages in the cluster are validated.

By default, similar [page validation](#) is performed automatically while a backup is taken by `pg_probackup`. The `checkdb` command enables you to perform such page validation on demand, without taking any backup copies, even if the cluster is not backed up using `pg_probackup` at all.

To perform cluster verification, `pg_probackup` needs to connect to the cluster to be verified. In general, it is enough to specify the backup instance of this cluster for `pg_probackup` to determine the required connection options. However, if `-B` and `--instance` options are omitted, you have to provide [connection options](#) and `data_dir` via environment variables or command-line options.

Physical verification cannot detect logical inconsistencies, missing or nullified blocks and entire files, or similar anomalies. Extensions [amcheck](#) and [amcheck_next](#) provide a partial solution to these problems.

If you would like, in addition to physical verification, to verify all indexes in all databases using these extensions, you can specify the `--amcheck` flag when running the `checkdb` command:

```
pg_probackup checkdb -D data_dir --amcheck [connection_options]
```

You can skip physical verification by specifying the `--skip-block-validation` flag. In this case, you can omit `backup_dir` and `data_dir` options, only [connection options](#) are mandatory:

```
pg_probackup checkdb --amcheck --skip-block-validation [connection_options]
```

Logical verification can be done more thoroughly with the `--heapallindexed` flag by checking that all heap tuples that should be indexed are actually indexed, but at the higher cost of CPU, memory, and I/O consumption.

Validating a Backup

`pg_probackup` calculates checksums for each file in a backup during the backup process. The process of checking checksums of backup data files is called *the backup validation*. By default, validation is run immediately after the backup is taken and right before the restore, to detect possible backup corruption.

Note

The backup validation includes checking checksums for CFS files.

If you would like to skip backup validation, you can specify the `--no-validate` flag when running [backup](#) and [restore](#) commands.

To ensure that all the required backup files are present and can be used to restore the database cluster, you can run the [validate](#) command with the exact [recovery target options](#) you are going to use for recovery.

For example, to check that you can restore the database cluster from a backup copy up to transaction ID 4242, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name --recovery-target-xid=4242
```

If validation completes successfully, `pg_probackup` displays the corresponding message. If validation fails, you will receive an error message with the exact time, transaction ID, and LSN up to which the recovery is possible.

If you specify `backup_id` via `-i/--backup-id` option, then only the backup copy with specified backup ID will be validated. If `backup_id` is specified with [recovery target options](#), the `validate` command will check whether it is possible to restore the specified backup to the specified recovery target.

For example, to check that you can restore the database cluster from a backup copy with the `PT8XFX` backup ID up to the specified timestamp, run this command:

```
pg_probackup validate -B backup_dir --instance instance_name -i PT8XFX --recovery-  
target-time="2017-05-18 14:18:11+03"
```

If you specify the *backup_id* of an incremental backup, all its parents starting from FULL backup will be validated.

If you omit all the parameters, all backups are validated.

Restoring a Cluster

To restore the database cluster from a backup, run the [restore](#) command with at least the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -i backup_id
```

Where:

- *backup_dir* is the backup catalog that stores all backup files and meta information.
- *instance_name* is the backup instance for the cluster to be restored.
- *backup_id* specifies the backup to restore the cluster from. If you omit this option, `pg_probackup` uses the latest valid backup available for the specified instance. If you specify an incremental backup to restore, `pg_probackup` automatically restores the underlying full backup and then sequentially applies all the necessary increments.

Once the `restore` command is complete, start the database service.

If you restore [ARCHIVE](#) backups, perform [PITR](#), or specify the `--restore-as-replica` flag with the `restore` command to set up a standby server, `pg_probackup` creates a recovery configuration file once all data files are copied into the target directory. This file includes the minimal settings required for recovery, except for the password in the [primary_conninfo](#) parameter; you have to add the password manually or use the `--primary-conninfo` option, if required. For Postgres Pro 11, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file and then includes it into `postgresql.auto.conf`.

If you are restoring a [STREAM](#) backup, the restore is complete at once, with the cluster returned to a self-consistent state at the point when the backup was taken. For [ARCHIVE](#) backups, Postgres Pro replays all available archived WAL segments, so the cluster is restored to the latest state possible within the current timeline. You can change this behavior by using the [recovery target options](#) with the `restore` command, as explained in [the section called “Performing Point-in-Time \(PITR\) Recovery”](#).

If the cluster to restore contains tablespaces, `pg_probackup` restores them to their original location by default. To restore tablespaces to a different location, use the `--tablespace-mapping/-T` option. Otherwise, restoring the cluster on the same host will fail if tablespaces are in use, because the backup would have to be written to the same directories.

When using the `--tablespace-mapping/-T` option, you must provide absolute paths to the old and new tablespace directories. If a path happens to contain an equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces. For example:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -j 4 -  
i backup_id -T tablespace1_dir=tablespace1_newdir -T tablespace2_dir=tablespace2_newdir
```

To restore the cluster on a remote host, follow the instructions in [the section called “Using pg_probackup in the Remote Mode”](#).

Note

By default, the [restore](#) command validates the specified backup before restoring the cluster. If you run regular backup validations and would like to save time when restoring the cluster, you can specify the `--no-validate` flag to skip validation and speed up the recovery.

Incremental Restore

The speed of restore from backup can be significantly improved by replacing only invalid and changed pages in already existing Postgres Pro data directory using [incremental restore options](#) with the [restore](#) command.

To restore the database cluster from a backup in incremental mode, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name -D data_dir -
I incremental_mode
```

Where *incremental_mode* can take one of the following values:

- **CHECKSUM** — read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with checksum and LSN not matching with corresponding page in backup. This is the simplest, the most fool-proof incremental mode. Recommended to use by default.
- **LSN** — read the *pg_control* in the data directory to obtain redo LSN and redo TLI, which allows you to determine a point in history(shiftpoint), where data directory state shifted from target backup chain history. If shiftpoint is not within reach of backup chain history, then restore is aborted. If shiftpoint is within reach of backup chain history, then read all data files in the data directory, validate header and checksum in every page and replace only invalid pages and those with LSN greater than shiftpoint. This mode offers a greater speed up compared to CHECKSUM, but rely on two conditions to be met. First, [data checksums](#) parameter must be enabled in data directory (to avoid corruption due to hint bits). This condition will be checked at the start of incremental restore and the operation will be aborted if checksums are disabled. Second, the *pg_control* file must be synched with state of data directory. This condition cannot be checked at the start of restore, so it is a user responsibility to ensure that *pg_control* contain valid information. Therefore it is not recommended to use LSN mode in any situation, where *pg_control* cannot be trusted or has been tampered with: after *pg_resetxlog* execution, after restore from backup without recovery been run, etc.
- **NONE** — regular restore without any incremental optimizations.

Regardless of chosen incremental mode, *pg_probackup* will check, that postmaster in given destination directory is not running and *system-identifier* is the same as in the backup.

Suppose you want to return an old master as replica after switchover using incremental restore in LSN mode:

Instance	Version	ID	Recovery Time		Mode	WAL Mode	TLI	Time
Data	WAL	Zalg	Zratio	Start LSN	Stop LSN	Status		
node	12		QBRNBP	2020-06-11 17:40:58+03	DELTA	ARCHIVE	16/15	40s

INFO: Restore of backup QBRNBP completed.
```

Note

Incremental restore is possible only for backups with `program_version` equal or greater than 2.4.0.

Partial Restore

If you have enabled [partial restore](#) before taking backups, you can restore only some of the databases using [partial restore options](#) with the [restore](#) commands.

To restore the specified databases only, run the [restore](#) command with the following options:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=database_name
```

The `--db-include` option can be specified multiple times. For example, to restore only databases `db1` and `db2`, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-include=db1 --db-include=db2
```

To exclude one or more databases from restore, use the `--db-exclude` option:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=database_name
```

The `--db-exclude` option can be specified multiple times. For example, to exclude the databases `db1` and `db2` from restore, run the following command:

```
pg_probackup restore -B backup_dir --instance instance_name --db-exclude=db1 --db-exclude=db2
```

Partial restore relies on lax behavior of Postgres Pro recovery process toward truncated files. For recovery to work properly, files of excluded databases are restored as files of zero size. After the Postgres Pro cluster is successfully started, you must drop the excluded databases using `DROP DATABASE` command.

To decouple a single cluster containing multiple databases into separate clusters with minimal downtime, you can do partial restore of the cluster as a standby using the `--restore-as-replica` option for specific databases.

Note

The `template0` and `template1` databases are always restored.

Note

Due to recovery specifics of Postgres Pro versions earlier than 12, it is advisable that you set the [hot standby](#) parameter to `off` when running partial restore of a Postgres Pro cluster of version earlier than 12. Otherwise the recovery may fail.

Performing Point-in-Time (PITR) Recovery

If you have enabled [continuous WAL archiving](#) before taking backups, you can restore the cluster to its state at an arbitrary point in time (recovery target) using [recovery target options](#) with the [restore](#) command.

You can use both STREAM and ARCHIVE backups for point in time recovery as long as the WAL archive is available at least starting from the time the backup was taken. If `-i/--backup-id` option is omitted, `pg_probackup` automatically chooses the backup that is the closest to the specified recovery target and starts the restore process, otherwise `pg_probackup` will try to restore the specified backup to the specified recovery target.

- To restore the cluster state at the exact time, specify the `--recovery-target-time` option, in the timestamp format. For example:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-time="2017-05-18 14:18:11+03"
```

- To restore the cluster state up to a specific transaction ID, use the `--recovery-target-xid` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-xid=687
```

- To restore the cluster state up to the specific LSN, use `--recovery-target-lsn` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-lsn=16/B374D848
```

- To restore the cluster state up to the specific named restore point, use `--recovery-target-name` option:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target-name="before_app_upgrade"
```

- To restore the backup to the latest state available in the WAL archive, use `--recovery-target` option with `latest` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target="latest"
```

- To restore the cluster to the earliest point of consistency, use `--recovery-target` option with the `immediate` value:

```
pg_probackup restore -B backup_dir --instance instance_name --recovery-target='immediate'
```

Using pg_probackup in the Remote Mode

`pg_probackup` supports the remote mode that allows you to perform `backup` and `restore` operations remotely via SSH. In this mode, the backup catalog is stored on a local system, while Postgres Pro instance to be backed up is located on a remote system. You must have `pg_probackup` installed on both systems.

Note

`pg_probackup` relies on passwordless SSH connection for communication between the hosts.

Note

In addition to SSH connection, `pg_probackup` uses a regular connection to the database to manage the remote operation. See the section [Configuring the Database Cluster](#) for details of how to set up a database connection.

The typical workflow is as follows:

- On your backup host, configure `pg_probackup` as explained in the section [Installation and Setup](#). For the `add-instance` and `set-config` commands, make sure to specify [remote options](#) that point to the database host with the Postgres Pro instance.
- If you would like to take remote backups in [PAGE](#) mode, or rely on [ARCHIVE](#) WAL delivery mode, or use [PITR](#), configure continuous WAL archiving from the database host to the backup host as explained in the section [Setting up continuous WAL archiving](#). For the `archive-push` and `archive-get` commands, you must specify the [remote options](#) that point to the backup host with the backup catalog.
- Run `backup` or `restore` commands with [remote options on the backup host](#). `pg_probackup` connects to the remote system via SSH and creates a backup locally or restores the previously taken backup on the remote system, respectively.

For example, to create an archive full backup of a Postgres Pro cluster located on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

To restore the latest available backup on a remote system with host address `192.168.0.2` on behalf of the `postgres` user via SSH connection through port `2302`, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302
```

Restoring an [ARCHIVE](#) backup or performing [PITR](#) in the remote mode require additional information: destination address, port and username for establishing an SSH connection **from** the host with database **to** the host with the backup catalog. This information will be used by the `restore_command` to copy WAL segments from the archive to the Postgres Pro `pg_wal` directory.

To solve this problem, you can use [Remote WAL Archive Options](#).

For example, to restore latest backup on remote system using remote mode through SSH connection to user `postgres` on host with address `192.168.0.2` via port `2302` and user `backup` on backup catalog host with address `192.168.0.3` via port `2303`, run:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --archive-host=192.168.0.3 --archive-port=2303 --archive-user=backup
```

Provided arguments will be used to construct the `restore_command`:

```
restore_command = '"install_dir/pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Alternatively, you can use the `--restore-command` option to provide the entire `restore_command`:

```
pg_probackup restore -B backup_dir --instance instance_name --remote-user=postgres --remote-host=192.168.0.2 --remote-port=2302 --restore-command='"install_dir/pg_probackup" archive-get -B "backup_dir" --instance instance_name --wal-file-path=%p --wal-file-name=%f --remote-host=192.168.0.3 --remote-port=2303 --remote-user=backup'
```

Note

The remote mode is currently unavailable for Windows systems.

Running pg_probackup on Parallel Threads

[backup](#), [restore](#), [merge](#), [delete](#), [catchup](#), [checkdb](#), and [validate](#) processes can be executed on several parallel threads. This can significantly speed up pg_probackup operation given enough resources (CPU cores, disk, and network bandwidth).

Parallel execution is controlled by the `-j/--threads` command-line option. For example, to create a backup using four parallel threads, run:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL -j 4
```

Note

Parallel restore applies only to copying data from the backup catalog to the data directory of the cluster. When Postgres Pro server is started, WAL records need to be replayed, and this cannot be done in parallel.

Configuring pg_probackup

Once the backup catalog is initialized and a new backup instance is added, you can use the `pg_probackup-up.conf` configuration file located in the `backup_dir/backups/instance_name` directory to fine-tune pg_probackup configuration.

For example, [backup](#) and [checkdb](#) commands use a regular Postgres Pro connection. To avoid specifying [connection options](#) each time on the command line, you can set them in the `pg_probackup.conf` configuration file using the [set-config](#) command.

Note

It is **not recommended** to edit `pg_probackup.conf` manually.

Initially, `pg_probackup.conf` contains the following settings:

- `PGDATA` — the path to the data directory of the cluster to back up.
- `system-identifier` — the unique identifier of the Postgres Pro instance.

Additionally, you can define [remote](#), [retention](#), [logging](#), and [compression](#) settings using the `set-config` command:

```
pg_probackup set-config -B backup_dir --instance instance_name
[--external-dirs=external_directory_path] [remote_options] [connection_options]
[retention_options] [logging_options]
```

To view the current settings, run the following command:

```
pg_probackup show-config -B backup_dir --instance instance_name
```

You can override the settings defined in `pg_probackup.conf` when running pg_probackup [commands](#) via the corresponding environment variables and/or command line options.

Specifying Connection Settings

If you define connection settings in the `pg_probackup.conf` configuration file, you can omit connection options in all the subsequent pg_probackup commands. However, if the corresponding environment variables are set, they get higher priority. The options provided on the command line overwrite both environment variables and configuration file settings.

If nothing is given, the default values are taken. By default pg_probackup tries to use local connection via Unix domain socket (`localhost` on Windows) and tries to get the database name and the user name from the `PGUSER` environment variable or the current OS user name.

Managing the Backup Catalog

With `pg_probackup`, you can manage backups from the command line:

- [View backup information](#)
- [View WAL Archive Information](#)
- [Validate backups](#)
- [Merge backups](#)
- [Delete backups](#)

Viewing Backup Information

To view the list of existing backups for every instance, run the command:

```
pg_probackup show -B backup_dir
```

`pg_probackup` displays the list of all the available backups. For example:

```
BACKUP INSTANCE 'node'
```

=====										
Instance	Version	ID	Recovery time		Mode	WAL Mode	TLI	Time	Data	
WAL	Zalg	Zratio	Start LSN	Stop LSN	Status					
=====										
node	10		PYSUE8	2019-10-03 15:51:48+03	FULL	ARCHIVE	1/0	16s	9047kB

16MB	none	1.00	0/15000060	0/15000198	OK					
node	10		P7XDJA	2018-04-29 05:28:36+03	PTRACK	STREAM	1/1	21s	32MB	
32MB	none	1.00	0/13000028	0/13000198	OK					
node	10		P7XDHU	2018-04-29 05:27:59+03	PAGE	STREAM	1/1	15s	33MB	
16MB	none	1.00	0/11000028	0/110001D0	OK					
node	10		P7XDHB	2018-04-29 05:27:15+03	FULL	STREAM	1/0	11s	39MB	
16MB	none	1.00	0/F000028	0/F000198	OK					

For each backup, the following information is provided:

- **Instance** — the instance name.
- **Version** — Postgres Pro major version.
- **ID** — the backup identifier.
- **Recovery time** — the earliest moment for which you can restore the state of the database cluster.
- **Mode** — the method used to take this backup. Possible values: `FULL`, `PAGE`, `DELTA`, `PTRACK`.
- **WAL Mode** — WAL delivery mode. Possible values: `STREAM` and `ARCHIVE`.
- **TLI** — timeline identifiers of the current backup and its parent.
- **Time** — the time it took to perform the backup.
- **Data** — the size of the data files in this backup. This value does not include the size of WAL files. For `STREAM` backups, the total size of the backup can be calculated as `Data + WAL`.
- **WAL** — the uncompressed size of WAL files that need to be applied during recovery for the backup to reach a consistent state.
- **compress-alg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as “uncompressed-bytes” / “data-bytes”.
- **Start LSN** — WAL log sequence number corresponding to the start of the backup process. REDO point for Postgres Pro recovery process to start from.

- **Stop LSN** — WAL log sequence number corresponding to the end of the backup process. Consistency point for Postgres Pro recovery process.
- **Status** — backup status. Possible values:
 - **OK** — the backup is complete and valid.
 - **DONE** — the backup is complete, but was not validated.
 - **RUNNING** — the backup is in progress.
 - **MERGING** — the backup is being merged.
 - **MERGED** — the backup data files were successfully merged, but its metadata is in the process of being updated. Only full backups can have this status.
 - **DELETING** — the backup files are being deleted.
 - **CORRUPT** — some of the backup files are corrupt.
 - **ERROR** — the backup was aborted because of an unexpected error.
 - **ORPHAN** — the backup is invalid because one of its parent backups is corrupt or missing.
 - **HIDDEN_FOR_TEST** — a test script marked the backup as nonexistent. (pg_probackup never sets this status by itself.)

You can restore the cluster from the backup only if the backup status is **OK** or **DONE**.

To get more detailed information about the backup, run the `show` command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

The sample output is as follows:

```
#Configuration
backup-mode = FULL
stream = false
compress-alg = zlib
compress-level = 1
from-replica = false

#Compatibility
block-size = 8192
wal-block-size = 8192
checksum-version = 1
program-version = 2.1.3
server-version = 10

#Result backup info
timelineid = 1
start-lsn = 0/04000028
stop-lsn = 0/040000f8
start-time = '2017-05-16 12:57:29'
end-time = '2017-05-16 12:57:31'
end-validation-time = '2017-05-16 12:58:10'
recovery-xid = 597
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-05-16 12:57:31'
data-bytes = 22288792
wal-bytes = 16777216
uncompressed-bytes = 39961833
pgdata-bytes = 39859393
status = OK
parent-backup-id = 'PT8XFX'
primary_conninfo = 'user=backup passfile=/var/lib/pgsql/.pgpass port=5432
sslmode=disable sslcompression=1 target_session_attrs=any'
```

Detailed output has additional attributes:

- `compress-alg` — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- `compress-level` — compression level used during backup.
- `from-replica` — was this backup taken on standby? Possible values: 1, 0.
- `block-size` — the [block_size](#) setting of Postgres Pro cluster at the backup start.
- `checksum-version` — are [data_checksums](#) enabled in the backed up Postgres Pro cluster? Possible values: 1, 0.
- `program-version` — full version of `pg_probackup` binary used to create the backup.
- `start-time` — the backup start time.
- `end-time` — the backup end time.
- `end-validation-time` — the backup validation end time.
- `expire-time` — the point in time when a pinned backup can be removed in accordance with retention policy. This attribute is only available for pinned backups.
- `uncompressed-bytes` — the size of data files before adding page headers and applying compression. You can evaluate the effectiveness of compression by comparing `uncompressed-bytes` to `data-bytes` if compression is used.
- `pgdata-bytes` — the size of Postgres Pro cluster data files at the time of backup. You can evaluate the effectiveness of an incremental backup by comparing `pgdata-bytes` to `uncompressed-bytes`.
- `recovery-xid` — transaction ID at the backup end time.
- `parent-backup-id` — ID of the parent backup. Available only for incremental backups.
- `primary_conninfo` — libpq connection parameters used to connect to the Postgres Pro cluster to take this backup. The password is not included.
- `note` — text note attached to backup.
- `content-crc` — CRC32 checksum of `backup_content.control` file. It is used to detect corruption of backup metainformation.

You can also get the detailed information about the backup in the JSON format:

```
pg_probackup show -B backup_dir --instance instance_name --format=json -i backup_id
```

The sample output is as follows:

```
[
  {
    "instance": "node",
    "backups": [
      {
        "id": "PT91HZ",
        "parent-backup-id": "PT8XFX",

Viewing WAL Archive Information

To view the information about WAL archive for every instance, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive
```

pg_probackup displays the list of all the available WAL files grouped by timelines. For example:

```
ARCHIVE INSTANCE 'node'
```

TLI	Parent TLI	Switchpoint	Min Segno	Max Segno	N
segments	Size	Zalg Zratio	N backups	Status	
5	1	0/B000000	000000050000000000000000B	000000050000000000000000C	2
	685kB	lz4 48.00	0	OK	
4	3	0/18000000	00000004000000000000000018	0000000400000000000000001A	3
	648kB	zstd 77.00	0	OK	
3	2	0/15000000	00000003000000000000000015	00000003000000000000000017	3
	648kB	zstd 77.00	0	OK	
2	1	0/B000108	000000020000000000000000B	00000002000000000000000015	5
	892kB	zstd 94.00	1	DEGRADED	
1	0	0/0	00000001000000000000000001	000000010000000000000000A	10
	8774kB	zstd 19.00	1	OK	

For each timeline, the following information is provided:

- **TLI** — timeline identifier.
- **Parent TLI** — identifier of the timeline from which this timeline branched off.
- **Switchpoint** — LSN of the moment when the timeline branched off from its parent timeline.
- **Min Segno** — the first WAL segment belonging to the timeline.
- **Max Segno** — the last WAL segment belonging to the timeline.
- **N segments** — number of WAL segments belonging to the timeline.
- **Size** — the size that files take on disk.
- **Zalg** — compression algorithm used during backup. Possible values: `zlib`, `pglz`, `lz4`, `zstd`, `none`.
- **Zratio** — compression ratio calculated as `N segments * wal_segment_size * wal_block_size / Size`.
- **N backups** — number of backups belonging to the timeline. To get the details about backups, use the JSON format.
- **Status** — status of the WAL archive for this timeline. Possible values:
 - **OK** — all WAL segments between **Min Segno** and **Max Segno** are present.
 - **DEGRADED** — some WAL segments between **Min Segno** and **Max Segno** are missing. To find out which files are lost, view this report in the JSON format.

To get more detailed information about the WAL archive in the JSON format, run the command:

```
pg_probackup show -B backup_dir [--instance instance_name] --archive --format=json
```

The sample output is as follows:

```

```

Most fields are consistent with the plain format, with some exceptions:

- The size is in bytes.
- The `closest-backup-id` attribute contains the ID of the most recent valid backup that belongs to one of the previous timelines. You can use this backup to perform point-in-time recovery to this timeline. If such a backup does not exist, this string is empty.
- The `lost-segments` array provides with information about intervals of missing segments in `DEGRADED` timelines. In `OK` timelines, the `lost-segments` array is empty.
- The `backups` array lists all backups belonging to the timeline. If the timeline has no backups, this array is empty.

Configuring Retention Policy

With `pg_probackup`, you can configure retention policy to remove redundant backups, clean up unneeded WAL files, as well as pin specific backups to ensure they are kept for the specified time, as explained in the sections below. All these actions can be combined together in any way.

Removing Redundant Backups

By default, all backup copies created with `pg_probackup` are stored in the specified backup catalog. To save disk space, you can configure retention policy to remove redundant backup copies.

To configure retention policy, set one or more of the following variables in the `pg_probackup.conf` file via [set-config](#):

```
--retention-redundancy=redundancy
```

Specifies **the number of full backup copies** to keep in the backup catalog.

```
--retention-window=window
```

Defines the earliest point in time for which `pg_probackup` can complete the recovery. This option is set in **the number of days** from the current moment. For example, if `retention-window=7`, `pg_probackup` must keep at least one backup copy that is older than seven days, with all the corresponding WAL files, and all the backups that follow.

If both `--retention-redundancy` and `--retention-window` options are set, both these conditions have to be taken into account when purging the backup catalog. For example, if you set `--retention-redundancy=2` and `--retention-window=7`, `pg_probackup` has to keep two full backup copies, as well as all the backups required to ensure recoverability for the last seven days:

```
pg_probackup set-config -B backup_dir --instance instance_name --retention-redundancy=2  
--retention-window=7
```

It is recommended to always keep at least two last parent full backups to avoid errors when creating incremental backups.

To clean up the backup catalog in accordance with retention policy, you have to run the [delete](#) command with [retention flags](#), as shown below, or use the [backup](#) command with these flags to process the outdated backup copies right when the new backup is created.

For example, to remove all backup copies that no longer satisfy the defined retention policy, run the following command with the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

If you would like to also remove the WAL files that are no longer required for any of the backups, you should also specify the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --delete-wal
```

You can also set or override the current retention policy by specifying `--retention-redundancy` and `--retention-window` options directly when running `delete` or `backup` commands:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --  
retention-window=7 --retention-redundancy=2
```

Since incremental backups require that their parent full backup and all the preceding incremental backups are available, if any of such backups expire, they still cannot be removed while at least one incremental backup in this chain satisfies the retention policy. To avoid keeping expired backups that are still required to restore an active incremental one, you can merge them with this backup using the `--merge-expired` flag when running [backup](#) or [delete](#) commands.

Suppose you have backed up the `node` instance in the `backup_dir` directory, with the `--retention-window` option set to 7, and you have the following backups available on April 10, 2019:

```
BACKUP INSTANCE 'node'
```

Instance	Version	ID	Recovery time		Mode	WAL	TLI	Time	Data
WAL	Zalg	Zratio	Start	LSN	Stop LSN	Status			
node	10		P7XDHR	2019-04-10 05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/18000059	0/18000197	OK				
node	10		P7XDQV	2019-04-08 05:32:59+03	PAGE	STREAM	1/0	11s	19MB
16MB	none	1.0	0/15000060	0/15000198	OK				
node	10		P7XDJA	2019-04-03 05:28:36+03	DELTA	STREAM	1/0	21s	32MB
16MB	none	1.0	0/13000028	0/13000198	OK				
-----retention window-----									
node	10		P7XDHU	2019-04-02 05:27:59+03	PAGE	STREAM	1/0	31s	33MB
16MB	none	1.0	0/11000028	0/110001D0	OK				
node	10		P7XDHB	2019-04-01 05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/F000028	0/F000198	OK				
node	10		P7XDFT	2019-03-29 05:26:25+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/D000028	0/D000198	OK				

Even though P7XDHB and P7XDHU backups are outside the retention window, they cannot be removed as it invalidates the succeeding incremental backups P7XDJA and P7XDQV that are still required, so, if you run the [delete](#) command with the `--delete-expired` flag, only the P7XDFT full backup will be removed.

With the `--merge-expired` option, the P7XDJA backup is merged with the underlying P7XDHU and P7XDHB backups and becomes a full one, so there is no need to keep these expired backups anymore:

```
pg_probackup delete -B backup_dir --instance node --delete-expired --merge-expired
pg_probackup show -B backup_dir
```

```
BACKUP INSTANCE 'node'
```

Instance	Version	ID	Recovery time		Mode	WAL	TLI	Time	Data
WAL	Zalg	Zratio	Start	LSN	Stop LSN	Status			
node	10		P7XDHR	2019-04-10 05:27:15+03	FULL	STREAM	1/0	11s	200MB
16MB	none	1.0	0/18000059	0/18000197	OK				
node	10		P7XDQV	2019-04-08 05:32:59+03	PAGE	STREAM	1/0	11s	19MB
16MB	none	1.0	0/15000060	0/15000198	OK				
node	10		P7XDJA	2019-04-03 05:28:36+03	FULL	STREAM	1/0	21s	32MB
16MB	none	1.0	0/13000028	0/13000198	OK				

The Time field for the merged backup displays the time required for the merge.

Pinning Backups

If you need to keep certain backups longer than the established retention policy allows, you can pin them for arbitrary time. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=30d
```

This command sets the expiration time of the specified backup to 30 days starting from the time indicated in its `recovery-time` attribute.

You can also explicitly set the expiration time for a backup using the `--expire-time` option. For example:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --expire-time="2020-01-01 00:00:00+03"
```

Alternatively, you can use the `--ttl` and `--expire-time` options with the [backup](#) command to pin the newly created backup:

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --ttl=30d
```

```
pg_probackup backup -B backup_dir --instance instance_name -b FULL --expire-
time="2020-01-01 00:00:00+03"
```

To check if the backup is pinned, run the [show](#) command:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the backup is pinned, it has the `expire-time` attribute that displays its expiration time:

```
...
recovery-time = '2017-05-16 12:57:31'
expire-time = '2020-01-01 00:00:00+03'
data-bytes = 22288792
...
```

You can unpin the backup by setting the `--ttl` option to zero:

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id --ttl=0
```

Note

A pinned incremental backup implicitly pins all its parent backups. If you unpin such a backup later, its implicitly pinned parents will also be automatically unpinned.

Configuring WAL Archive Retention Policy

When [continuous WAL archiving](#) is enabled, archived WAL segments can take a lot of disk space. Even if you delete old backup copies from time to time, the `--delete-wal` flag can purge only those WAL segments that do not apply to any of the remaining backups in the backup catalog. However, if point-in-time recovery is critical only for the most recent backups, you can configure WAL archive retention policy to keep WAL archive of limited depth and win back some more disk space.

To configure WAL archive retention policy, you have to run the [set-config](#) command with the `--wal-depth` option that specifies the number of backups that can be used for PITR. This setting applies to all the timelines, so you should be able to perform PITR for the same number of backups on each timeline, if available. [Pinned backups](#) are not included into this count: if one of the latest backups is pinned, `pg_probackup` ensures that PITR is possible for one extra backup.

To remove WAL segments that do not satisfy the defined WAL archive retention policy, you simply have to run the [delete](#) or [backup](#) command with the `--delete-wal` flag. For archive backups, WAL segments between `Start LSN` and `Stop LSN` are always kept intact, so such backups remain valid regardless of the `--wal-depth` setting and can still be restored, if required.

You can also use the `--wal-depth` option with the [delete](#) and [backup](#) commands to override the previously defined WAL archive retention policy and purge old WAL segments on the fly.

Suppose you have backed up the `node` instance in the `backup_dir` directory and configured [continuous WAL archiving](#):

```
pg_probackup show -B backup_dir --instance node
```

```
BACKUP INSTANCE 'node'
```

```
=====
Instance  Version  ID      Recovery Time      Mode  WAL Mode  TLI  Time  Data

16MB none  1.00  0/3C000028  0/3C000198  OK
node      11      PZ7YFO  2019-10-11 19:43:04+03 FULL   STREAM      1/0    10s    30MB
16MB none  1.00  0/2000028   0/200ADD8   OK
```

You can check the state of the WAL archive by running the [show](#) command with the `--archive` flag:

```
pg_probackup show -B backup_dir --instance node --archive
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno                      Max Segno                      N
segments Size  Zalg  Zratio  N backups  Status
=====
1    0          0/0          00000001000000000000000001  00000001000000000000000047  71
      36MB  zstd  31.00   6              OK
=====
```

WAL purge without `--wal-depth` cannot achieve much, only one segment is removed:

```
pg_probackup delete -B backup_dir --instance node --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno                      Max Segno                      N
segments Size  Zalg  Zratio  N backups  Status
=====
1    0          0/0          00000001000000000000000002  00000001000000000000000047  70
      34MB  zstd  32.00   6              OK
=====
```

If you would like, for example, to keep only those WAL segments that can be applied to the latest valid backup, set the `--wal-depth` option to 1:

```
pg_probackup delete -B backup_dir --instance node --delete-wal --wal-depth=1
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno                      Max Segno                      N
segments Size  Zalg  Zratio  N backups  Status
=====
1    0          0/0          00000001000000000000000046  00000001000000000000000047  2
      143kB  zstd  228.00  6              OK
=====
```

Alternatively, you can use the `--wal-depth` option with the [backup](#) command:

```
pg_probackup backup -B backup_dir --instance node -b DELTA --wal-depth=1 --delete-wal
```

```
ARCHIVE INSTANCE 'node'
```

```
=====
TLI  Parent TLI  Switchpoint  Min Segno                      Max Segno                      N

      72kB  zstd  228.00  7              OK
=====
```

Merging Backups

As you take more and more incremental backups, the total size of the backup catalog can substantially grow. To save disk space, you can merge incremental backups to their parent full backup by running the `merge` command, specifying the backup ID of the most recent incremental backup you would like to merge:

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
```

This command merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant. Thus, the merge operation is virtually equivalent to retaking a full backup and removing all the outdated backups, but it allows you to save much time, especially for large data volumes, as well as I/O and network traffic if you are using `pg_probackup` in the [remote](#) mode.

Before the merge, `pg_probackup` validates all the affected backups to ensure that they are valid. You can check the current backup status by running the [show](#) command with the backup ID:

```
pg_probackup show -B backup_dir --instance instance_name -i backup_id
```

If the merge is still in progress, the backup status is displayed as `MERGING`. For full backups, it can also be shown as `MERGED` while the metadata is being updated at the final stage of the merge. The merge is idempotent, so you can restart the merge if it was interrupted.

Deleting Backups

To delete a backup that is no longer required, run the following command:

```
pg_probackup delete -B backup_dir --instance instance_name -i backup_id
```

This command will delete the backup with the specified `backup_id`, together with all the incremental backups that descend from `backup_id`, if any. This way you can delete some recent incremental backups, retaining the underlying full backup and some of the incremental backups that follow it.

To delete obsolete WAL files that are not necessary to restore any of the remaining backups, use the `--delete-wal` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-wal
```

To delete backups that are expired according to the current retention policy, use the `--delete-expired` flag:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired
```

Expired backups cannot be removed while at least one incremental backup that satisfies the retention policy is based on them. If you would like to minimize the number of backups still required to keep incremental backups valid, specify the `--merge-expired` flag when running this command:

```
pg_probackup delete -B backup_dir --instance instance_name --delete-expired --merge-expired
```

In this case, `pg_probackup` searches for the oldest incremental backup that satisfies the retention policy and merges this backup with the underlying full and incremental backups that have already expired, thus making it a full backup. Once the merge is complete, the remaining expired backups are deleted.

Before merging or deleting backups, you can run the `delete` command with the `--dry-run` flag, which displays the status of all the available backups according to the current retention policy, without performing any irreversible actions.

To delete all backups with specific status, use the `--status`:

```
pg_probackup delete -B backup_dir --instance instance_name --status=ERROR
```

Deleting backups by status ignores established retention policies.

Cloning and Synchronizing Postgres Pro Instance

`pg_probackup` can create a copy of a Postgres Pro instance directly, without using the backup catalog. To do this, you can run the [catchup](#) command. It can be useful in the following cases:

- To add a new standby server.

Usually, [pg_basebackup](#) is used to create a copy of a Postgres Pro instance. If the data directory of the destination instance is empty, the `catchup` command works similarly, but it can be faster if run in parallel mode.

- To have a fallen-behind standby server “catch up” with master.

Under write-intensive load, replicas may fail to replay WAL fast enough to keep up with master and hence may lag behind. A usual solution to create a new replica and switch to it requires a lot of extra space and data transfer. The `catchup` command allows you to update an existing replica much faster by bringing differences from master.

`catchup` is different from other `pg_probackup` operations:

- The backup catalog is not required.
- STREAM WAL delivery mode is only supported.
- Copying external directories is not supported.
- DDL commands [CREATE TABLESPACE/DROP TABLESPACE](#) cannot be run simultaneously with `catchup`.
- `catchup` takes configuration files, such as `postgresql.conf`, `postgresql.auto.conf`, or `pg_hba.conf`, from the source server and overwrites them on the target server. The `--exclude-path` option allows you to keep the configuration files intact.

To prepare for cloning/synchronizing a Postgres Pro instance, set up the source server as follows:

- [Configure the database cluster](#) for the instance to copy.
- To copy from a remote server, [configure the remote mode](#).
- To use the PTRACK `catchup` mode, [set up PTRACK backups](#).

Before cloning/synchronizing a Postgres Pro instance, ensure that the source server is running and accepting connections. To clone/sync a Postgres Pro instance, on the server with the destination instance, you can run the [catchup](#) command as follows:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream [connection_options] [remote_options]
```

Where *catchup_mode* can take one of the following values:

- FULL — creates a full copy of the Postgres Pro instance. The data directory of the destination instance must be empty for this mode.
- DELTA — reads all data files in the data directory and creates an incremental copy for pages that have changed since the destination instance was shut down.
- PTRACK — tracking page changes on the fly, only reads and copies pages that have changed since the point of divergence of the source and destination instances.

Warning

PTRACK `catchup` mode requires PTRACK not earlier than 2.0 and hence, Postgres Pro not earlier than 11.

By specifying the `--stream` option, you can set [STREAM](#) WAL delivery mode of copying, which will include all the necessary WAL files by streaming them from the server via replication protocol.

You can use [connection_options](#) to specify the connection to the source database cluster. If it is located on a different server, also specify [remote_options](#).

If the source database cluster contains tablespaces that must be located in a different directory, additionally specify the `--tablespace-mapping` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --tablespace-mapping=OLDDIR=NEWDIR
```

To run the `catchup` command on parallel threads, specify the number of threads with the `--threads` option:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --threads=num_threads
```

Before cloning/synchronising a Postgres Pro instance, you can run the `catchup` command with the `--dry-run` flag to estimate the size of data files to be transferred, but make no changes on disk:

```
pg_probackup catchup -b catchup_mode --source-pgdata=path_to_pgdata_on_remote_server --  
destination-pgdata=path_to_local_dir --stream --dry-run
```

For example, assume that a remote standby server with the Postgres Pro instance having `/replica-pgdata` data directory has fallen behind. To sync this instance with the one in `/master-pgdata` data directory, you can run the `catchup` command in the `PTRACK` mode on four parallel threads as follows:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=PTRACK  
--remote-host=remote-hostname --remote-user=remote-unix-username -j 4 --exclude-  
path=postgresql.conf --exclude-path=postgresql.auto.conf --exclude-path=pg_hba.conf --  
exclude-path=pg_ident.conf
```

Note that in this example, the configuration files will not be overwritten during synchronization.

Another example shows how you can add a new remote standby server with the Postgres Pro data directory `/replica-pgdata` by running the `catchup` command in the `FULL` mode on four parallel threads:

```
pg_probackup catchup --source-pgdata=/master-pgdata --destination-pgdata=/replica-  
pgdata -p 5432 -d postgres -U remote-postgres-user --stream --backup-mode=FULL --  
remote-host=remote-hostname --remote-user=remote-unix-username -j 4
```

Command-Line Reference

Commands

This section describes `pg_probackup` commands. Optional parameters are enclosed in square brackets. For detailed parameter descriptions, see the section [Options](#).

version

```
pg_probackup version
```

Prints `pg_probackup` version and edition, as well as Postgres Pro version and edition.

help

```
pg_probackup help [command]
```

Displays the synopsis of `pg_probackup` commands. If one of the `pg_probackup` commands is specified, shows detailed information about the options that can be used with this command.

init

```
pg_probackup init -B backup_dir [--skip-if-exists] [s3_options] [--help]  
[logging_options]
```

Initializes the backup catalog in `backup_dir` that will store backup copies, WAL archive, and meta information for the backed up database clusters. If the specified `backup_dir` already exists, it must be empty. Otherwise, `pg_probackup` displays a corresponding error message. You can ignore this error by

specifying the `--skip-if-exists` option. Although the backup will not be initialized, the application will return 0 code.

For details, see the section [Initializing the Backup Catalog](#).

add-instance

```
pg_probackup add-instance -B backup_dir -D data_dir --instance instance_name
[--skip-if-exists] [s3_options] [--help] [logging_options]
```

Initializes a new backup instance inside the backup catalog *backup_dir* and generates the `pg_probackup.conf` configuration file that controls `pg_probackup` settings for the cluster with the specified *data_dir* data directory. If the catalog was already initialized, you can ignore the error by specifying `--skip-if-exists`.

For details, see the section [Adding a New Backup Instance](#).

del-instance

```
pg_probackup del-instance -B backup_dir --instance instance_name [s3_options] [--help]
[logging_options]
```

Deletes all backups and WAL files associated with the specified instance.

set-config

```
pg_probackup set-config -B backup_dir --instance instance_name
[--help] [--pgdata=pgdata-path]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--compress-algorithm=compression_algorithm] [--compress-level=compression_level]
[-d dbname] [-h host] [-p port] [-U username]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--restore-command=cmdline]
[remote_options] [remote_wal_archive_options] [logging_options] [s3_options]
```

Adds the specified connection, compression, retention, logging, and external directory settings into the `pg_probackup.conf` configuration file, or modifies the previously defined values.

For all available settings, see the [Options](#) section.

It is **not recommended** to edit `pg_probackup.conf` manually.

set-backup

```
pg_probackup set-backup -B backup_dir --instance instance_name -i backup_id
{--ttl=ttl | --expire-time=time}
[--note=backup_note] [s3_options] [--help] [logging_options]
```

Sets the provided backup-specific settings into the `backup.control` configuration file, or modifies the previously defined values.

```
--note=backup_note
```

Sets the text note for backup copy. If *backup_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The `'none'` value removes current note.

For all available pinning settings, see the section [Pinning Options](#).

show-config

```
pg_probackup show-config -B backup_dir --instance instance_name [--format=plain|json]
[s3_options]
[--no-scale-units] [logging_options]
```

Displays all the current `pg_probackup` configuration settings, including those that are specified in the `pg_probackup.conf` configuration file located in the `backup_dir/backups/instance_name` directory and those that were provided on a command line. You can specify the `--format=json` option to get the result in the JSON format. By default, configuration settings are shown as plain text.

You can also specify the `--no-scale-units` option to display time and memory configuration settings in their base (unscaled) units. Otherwise, the values are scaled to larger units for optimal display. For example, if `archive-timeout` is 300, then 5min is displayed, but if `archive-timeout` is 301, then 301s is displayed. Also, if the `--no-scale-units` option is specified, configuration settings are displayed without units and for the JSON format, numeric and boolean values are not enclosed in quotes. This facilitates parsing the output.

To edit `pg_probackup.conf`, use the [set-config](#) command.

show

```
pg_probackup show -B backup_dir
[--help] [--instance instance_name [-i backup_id | --archive]] [--format=plain|json]
[--no-color] [--show-symlinks] [s3_options]
[logging_options]
```

Shows the contents of the backup catalog. If `instance_name` and `backup_id` are specified, shows detailed information about this backup. If the `--archive` option is specified, shows the contents of WAL archive of the backup catalog.

By default, the contents of the backup catalog is shown as plain text. You can specify the `--format=json` option to get the result in the JSON format. If `--no-color` flag is used, then the output is not colored.

If the `--show-symlinks` option is specified, the command also shows the links between [merged](#) backups and the original full backups that incremental backups were merged to.

For details on usage, see the sections [Managing the Backup Catalog](#) and [Viewing WAL Archive Information](#).

backup

```
pg_probackup backup -B backup_dir -b backup_mode --instance instance_name
[--help] [--j num_threads] [--progress]
[-C] [--stream [-S slot_name] [--temp-slot [=true|false|on|off]]] [--backup-pg-log]
[--no-validate] [--skip-block-validation]
[-w --no-password] [-W --password]
[--write-rate-limit=bitrate]
[--archive-timeout=timeout] [--external-dirs=external_directory_path]
[--no-sync] [--note=backup_note]
[connection_options] [compression_options] [remote_options]
[retention_options] [pinning_options] [logging_options] [s3_options]
```

Creates a backup copy of the Postgres Pro instance.

```
-b mode
--backup-mode=mode
```

Specifies the backup mode to use. Possible values are: [FULL](#), [DELTA](#), [PAGE](#), and [PTRACK](#).

```
-C
--smooth-checkpoint
```

Spreads out the checkpoint over a period of time. By default, `pg_probackup` tries to complete the checkpoint as soon as possible.

```
--stream
```

Makes a [STREAM](#) backup, which includes all the necessary WAL files by streaming them from the database server via replication protocol.

`--temp-slot [=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the backed up Postgres Pro instance. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

`--backup-pg-log`

Includes the log directory into the backup. This directory usually contains log messages. By default, log directory is excluded.

`-E external_directory_path`

`--external-dirs=external_directory_path`

Includes the specified directory into the backup by recursively copying its contents into a separate subdirectory in the backup catalog. This option is useful to back up scripts, SQL dump files, and configuration files located outside of the data directory. If you would like to back up several external directories, separate their paths by a colon on Unix and a semicolon on Windows.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the backup:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total backup time.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`--archive-timeout=wait_time`

Sets the timeout for WAL segment archiving and streaming, in seconds. By default, `pg_probackup` waits 300 seconds.

`--skip-block-validation`

Disables block-level checksum verification to speed up the backup process.

`--no-validate`

Skips automatic validation after the backup is taken. You can use this flag if you validate backups regularly and would like to save time when running backup operations.

`--no-sync`

Do not sync backed up files to disk. You can use this flag to speed up the backup process. Using this flag can result in data corruption in case of operating system or hardware crash. If you use

this option, it is recommended to run the [validate](#) command once the backup is complete to detect possible issues.

`--note=backup_note`

Sets the text note for backup copy. If *backup_note* contain newline characters, then only substring before first newline character will be saved. Max size of text note is 1 KB. The '*none*' value removes current note.

Additionally, [connection options](#), [retention options](#), [pinning options](#), [remote mode options](#), [compression options](#), [logging options](#), and [common options](#) can be used.

For details on usage, see the section [Creating a Backup](#).

restore

```
pg_probackup restore -B backup_dir --instance instance_name
[--help] [-D data_dir] [-i backup_id]
[-j num_threads] [--progress]
[-T OLDDIR=NEWDIR] [--external-mapping=OLDDIR=NEWDIR] [--skip-external-dirs]
[-R | --restore-as-replica] [--no-validate] [--skip-block-validation]
[--force] [--no-sync]
[--restore-command=cmdline]
[--primary-conninfo=primary_conninfo]
[-S | --primary-slot-name=slot_name]
[-X wal_dir | --waldir=wal_dir]
[recovery_target_options] [logging_options] [remote_options]
[partial_restore_options] [remote_wal_archive_options] [s3_options]
```

Restores the Postgres Pro instance from a backup copy located in the *backup_dir* backup catalog. If you specify a [recovery target option](#), `pg_probackup` finds the closest backup and restores it to the specified recovery target. If neither the backup ID nor recovery target options are provided, `pg_probackup` uses the most recent backup to perform the recovery.

`-R`

`--restore-as-replica`

Creates a minimal recovery configuration file to facilitate setting up a standby server. If the replication connection requires a password, you must specify the password manually in the [primary_conninfo](#) parameter as it is not included. For Postgres Pro 11 or lower, recovery settings are written into the `recovery.conf` file. Starting from Postgres Pro 12, `pg_probackup` writes these settings into the `probackup_recovery.conf` file in the data directory, and then includes them into the `postgresql.auto.conf` when the cluster is started.

`--primary-conninfo=primary_conninfo`

Sets the [primary_conninfo](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

Example: `--primary-conninfo="host=192.168.1.50 port=5432 user=foo password=foopass"`

`-S`

`--primary-slot-name=slot_name`

Sets the [primary_slot_name](#) parameter to the specified value. This option will be ignored unless the `-R` flag is specified.

`-T OLDDIR=NEWDIR`

`--tablespace-mapping=OLDDIR=NEWDIR`

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

`--external-mapping=OLDDIR=NEWDIR`

Relocates an external directory included into the backup from the `OLDDIR` to the `NEWDIR` directory at the time of recovery. Both `OLDDIR` and `NEWDIR` must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple directories.

`--skip-external-dirs`

Skip external directories included into the backup with the `--external-dirs` option. The contents of these directories will not be restored.

`--skip-block-validation`

Disables block-level checksum verification to speed up validation. During automatic validation before the restore only file-level checksums will be verified.

`--no-validate`

Skips backup validation. You can use this flag if you validate backups regularly and would like to save time when running restore operations.

`--restore-command=cmdline`

Sets the `restore_command` parameter to the specified command. For example: `--restore-command='cp /mnt/server/archivedir/%f "%p"'`

`--force`

Allows to ignore an invalid status of the backup. You can use this flag if you need to restore the Postgres Pro cluster from a corrupt or an invalid backup. Use with caution. If `PGDATA` contains a non-empty directory with system ID different from that of the backup being restored, [incremental restore](#) with this flag overwrites the directory contents (while an error occurs without the flag). If tablespaces are remapped through the `--tablespace-mapping` option into non-empty directories, the contents of such directories will be deleted.

`--no-sync`

Do not sync restored files to disk. You can use this flag to speed up restore process. Using this flag can result in data corruption in case of operating system or hardware crash. If it happens, you have to run the [restore](#) command again.

`-X wal_dir`

`--waldir=wal_dir`

Sets the directory to write WAL files to. By default WAL files will be placed in the `pg_wal` subdirectory of the target directory, but this option can be used to place them elsewhere. `wal_dir` must be an absolute path, which must not already exist, but if it does, it must be empty.

Additionally, [recovery target options](#), [remote mode options](#), [remote WAL archive options](#), [logging options](#), [partial restore options](#), and [common options](#) can be used.

For details on usage, see the section [Restoring a Cluster](#).

checkdb

`pg_probackup checkdb`

`[-B backup_dir] [--instance instance_name] [-D data_dir]`

`[--help] [-j num_threads] [--progress]`

`[--amcheck [--skip-block-validation] [--checkunique] [--heapallindexed]]`

`[connection_options] [logging_options]`

Verifies the Postgres Pro database cluster correctness by detecting physical and logical corruption.

--amcheck

Performs logical verification of indexes for the specified Postgres Pro instance if no corruption was found while checking data files. You must have the [amcheck](#) extension or the `amcheck_next` extension installed in the database to check its indexes. For databases without `amcheck`, index verification will be skipped. Additional options `--checkunique` and `--heapallindexed` are effective depending on the version of `amcheck` installed.

--checkunique

Verifies unique constraints during logical verification of indexes. You can use this flag only together with the `--amcheck` flag when the `amcheck` extension is installed in the database.

The verification of unique constraints is only possible if in the version of the `amcheck` extension you are using, the `bt_index_check` function takes the `checkunique` parameter.

--heapallindexed

Checks that all heap tuples that should be indexed are actually indexed. You can use this flag only together with the `--amcheck` flag.

This check is only possible if in the version of the `amcheck/amcheck_next` extension you are using, the `bt_index_check` function takes the `heapallindexed` parameter.

--skip-block-validation

Skip validation of data files. You can use this flag only together with the `--amcheck` flag, so that only logical verification of indexes is performed.

Additionally, [connection options](#) and [logging options](#) can be used.

For details on usage, see the section [Verifying a Cluster](#).

validate

```
pg_probackup validate -B backup_dir
[--help] [--instance instance_name] [-i backup_id]
[-j num_threads] [--progress]
[--skip-block-validation]
[recovery_target_options] [logging_options] [s3_options]
```

Verifies that all the files required to restore the cluster are present and are not corrupt. If `instance_name` is not specified, `pg_probackup` validates all backups available in the backup catalog. If you specify the `instance_name` without any additional options, `pg_probackup` validates all the backups available for this backup instance. If you specify the `instance_name` with a [recovery target option](#) and/or a `backup_id`, `pg_probackup` checks whether it is possible to restore the cluster using these options.

For details, see the section [Validating a Backup](#).

merge

```
pg_probackup merge -B backup_dir --instance instance_name -i backup_id
[--help] [-j num_threads] [--progress] [--no-validate] [--no-sync]
[logging_options]
```

Merges backups that belong to a common incremental backup chain. If you specify a full backup, it will be merged with its first incremental backup. If you specify an incremental backup, it will be merged to its parent full backup, together with all incremental backups between them. Once the merge is complete, the full backup takes in all the merged data, and the incremental backups are removed as redundant.

--no-validate

Skips automatic validation before and after merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the section [Merging Backups](#).

delete

```
pg_probackup delete -B backup_dir --instance instance_name
[--help] [-j num_threads] [--progress]
[--retention-redundancy=redundancy] [--retention-window=window] [--wal-depth=wal_depth]
[--delete-wal]
{-i backup_id | --delete-expired [--merge-expired] | --merge-expired | --
status=backup_status}
[--dry-run] [--no-validate] [--no-sync] [logging_options] [s3_options]
```

Deletes backup with specified *backup_id* or launches the retention purge of backups and archived WAL that do not satisfy the current retention policies.

`--no-validate`

Skips automatic validation before and after retention merge.

`--no-sync`

Do not sync merged files to disk. You can use this flag to speed up the retention merge process. Using this flag can result in data corruption in case of operating system or hardware crash.

For details, see the sections [Deleting Backups](#), [Retention Options](#), and [Configuring Retention Policy](#).

archive-push

```
pg_probackup archive-push -B backup_dir --instance instance_name
--wal-file-name=wal_file_name [--wal-file-path=wal_file_path]
[--help] [--no-sync] [--compress] [--no-ready-rename] [--overwrite]
[-j num_threads] [--batch-size=batch_size]
[--archive-timeout=timeout]
[--compress-algorithm=compression_algorithm]
[--compress-level=compression_level]
[remote_options] [logging_options] [s3_options]
```

Copies WAL files into the corresponding subdirectory of the backup catalog and validates the backup instance by *instance_name* and *system-identifier*. If parameters of the backup instance and the cluster do not match, this command fails with the following error message: Refuse to push WAL segment *segment_name* into archive. Instance parameters mismatch.

If the files to be copied already exists in the backup catalog, `pg_probackup` computes and compares their checksums. If the checksums match, `archive-push` skips the corresponding file and returns a successful execution code. Otherwise, `archive-push` fails with an error. If you would like to replace WAL files in the case of checksum mismatch, run the `archive-push` command with the `--overwrite` flag.

Each file is copied to a temporary file with the `.part` suffix. If the temporary file already exists, `pg_probackup` will wait `archive_timeout` seconds before discarding it. After the copy is done, atomic rename is performed. This algorithm ensures that a failed `archive-push` will not stall continuous archiving and that concurrent archiving from multiple sources into a single WAL archive has no risk of archive corruption.

The postgres server requests WAL segments one at a time. To speed up archiving, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

WAL segments copied to the archive are synced to disk unless the `--no-sync` flag is used.

You can use `archive-push` in the [archive_command](#) Postgres Pro parameter to set up [continuous WAL archiving](#).

For details, see sections [Archiving Options](#) and [Compression Options](#).

archive-get

```
pg_probackup archive-get -B backup_dir --instance instance_name --wal-file-  
path=wal_file_path --wal-file-name=wal_file_name  
[-j num_threads] [--batch-size=batch_size]  
[--prefetch-dir=prefetch_dir_path] [--no-validate-wal]  
[--help] [remote_options] [logging_options] [s3_options]
```

Copies WAL files from the corresponding subdirectory of the backup catalog to the cluster's write-ahead log location. This command is automatically set by `pg_probackup` as part of the `restore_command` when restoring backups using a WAL archive. You do not need to set it manually if you use local storage for backups or remote mode.

If you use S3 interface, to ensure that the Postgres Pro server has access to S3 storage to fetch WAL files during restore, you can specify the `--s3-config-file` option that defines the S3 configuration file with appropriate configuration settings, as described in [the section called “S3 Options”](#).

The postgres server requests WAL segments one at a time. To speed up recovery, you can specify the `--batch-size` option to copy WAL segments in batches of the specified size. If `--batch-size` option is used, then you can also specify the `-j` option to copy the batch of WAL segments on multiple threads.

For details, see section [Archiving Options](#).

catchup

```
pg_probackup catchup -b catchup_mode  
--source-pgdata=path_to_pgdata_on_remote_server  
--destination-pgdata=path_to_local_dir  
[--help] [-j | --threads=num_threads] [--dry-run]  
[--write-rate-limit=bitrate]  
[--stream [--temp-slot[=true|false|on|off]] [-P | --perm-slot] [-S | --slot=slot_name]]  
[--exclude-path=PATHNAME]  
[-T OLDDIR=NEWDIR]  
[-X | --waldir=wal_dir]  
[connection_options] [remote_options]  
[logging_options]
```

Creates a copy of a Postgres Pro instance without using the backup catalog.

```
-b catchup_mode  
--backup-mode=catchup_mode
```

Specifies the catchup mode to use. Possible values are: [FULL](#), [DELTA](#), and [PTRACK](#).

```
--source-pgdata=path_to_pgdata_on_remote_server
```

Specifies the path to the data directory of the instance to be copied. The path can be local or remote.

```
--destination-pgdata=path_to_local_dir
```

Specifies the path to the local data directory to copy to.

```
-j num_threads  
--threads=num_threads
```

Sets the number of parallel threads for `catchup` process.

```
--stream
```

Copies the instance in [STREAM](#) WAL delivery mode, including all the necessary WAL files by streaming them from the server via replication protocol. For `catchup`, it is enabled by default.

`--dry-run`

Displays the total size of the files to be transferred by `catchup`. This flag initiates a trial run of `catchup`, which does not actually create, delete or move files on disk. WAL streaming is skipped with `--dry-run`. This flag also allows you to check that all the options are correct and cloning/synchronising is ready to run.

`--write-rate-limit=bitrate`

Sets the rate of writing data to disk, in MBps or GBps. The default unit is MBps. For example: `--write-rate-limit=1GBps` or `--write-rate-limit=100` (MBps). The default value is 0 — no limitation.

If this option is specified, the following information is displayed at the end of the `catchup` operation:

- `written` — the amount of data written, in MB.
- `total time` — the time that elapsed between the first and last writes, in seconds. Note that this is not the total duration of the `catchup` operation.
- `sleep time` — the amount of forced delay time, in seconds.
- `average rate` — the actual average write rate, in MBps.

For example:

```
INFO: Rate limit: written 14975.445 MB, total time 17.163 s, sleep time 2.370 s,
      average rate 872.560715 MBps
```

`-x=path_prefix`

`--exclude-path=path_prefix`

Specifies a prefix for files to exclude from the synchronization of Postgres Pro instances during copying. The prefix must contain a path relative to the data directory of an instance. If the prefix specifies a directory, all files in this directory will not be synchronized.

Warning

This option is dangerous since excluding files from synchronization can result in incomplete synchronization; use with care.

`--temp-slot [=true|false|on|off]`

Creates a *temporary* physical replication slot for streaming WAL from the Postgres Pro instance being copied. `--temp-slot` is enabled by default. It ensures that all the required WAL segments remain available if WAL is rotated while the backup is in progress. This flag can only be used together with the `--stream` flag and cannot be used together with the `--perm-slot` flag. The default slot name is `pg_probackup_slot`. To change it, use the `--slot/-S` option and explicitly specify `--temp-slot` or `--temp-slot=true|on`.

`-P`

`--perm-slot`

Creates a *permanent* physical replication slot for streaming WAL from the Postgres Pro instance being copied. This flag can only be used together with the `--stream` flag and cannot be used together with the `--temp-slot` flag. The default slot name is `pg_probackup_perm_slot`, which can be changed using the `--slot/-S` option.

`-S slot_name`

`--slot=slot_name`

Specifies the replication slot to connect to for WAL streaming. This option can only be used together with the `--stream` flag.

```
-T OLDDIR=NEWDIR
--tablespace-mapping=OLDDIR=NEWDIR
```

Relocates the tablespace from the *OLDDIR* to the *NEWDIR* directory at the time of recovery. Both *OLDDIR* and *NEWDIR* must be absolute paths. If the path contains the equals sign (=), escape it with a backslash. This option can be specified multiple times for multiple tablespaces.

```
-X wal_dir
--waldir=wal_dir
```

Sets the directory to write WAL files to. By default WAL files will be placed in the *pg_wal* subdirectory of the target directory, but this option can be used to place them elsewhere. *wal_dir* must be an absolute path, which must not already exist, but if it does, it must be empty to perform *catchup* with *--catchup-mode=FULL*.

Additionally, [connection options](#), [remote mode options](#) can be used.

For details on usage, see the section [Cloning and Synchronizing Postgres Pro Instance](#).

Options

This section describes command-line options for *pg_probackup* commands. If the option value can be derived from an environment variable, this variable is specified below the command-line option, in the uppercase. Some values can be taken from the *pg_probackup.conf* configuration file located in the backup catalog.

For details, see [the section called “Configuring pg_probackup”](#).

If an option is specified using more than one method, command-line input has the highest priority, while the *pg_probackup.conf* settings have the lowest priority.

Common Options

The list of general options.

```
-B directory
--backup-path=directory
BACKUP_PATH
```

Specifies the absolute path to the backup catalog. Backup catalog is a directory where all backup files and meta information are stored. Since this option is required for most of the *pg_probackup* commands, you are recommended to specify it once in the *BACKUP_PATH* environment variable. In this case, you do not need to use this option each time on the command line.

```
-D directory
--pgdata=directory
PGDATA
```

Specifies the absolute path to the data directory of the database cluster. This option is mandatory only for the [add-instance](#) command. Other commands can take its value from the *PGDATA* environment variable, or from the *pg_probackup.conf* configuration file.

```
-i backup_id
--backup-id=backup_id
```

Specifies the unique identifier of the backup.

```
-j num_threads
--threads=num_threads
```

Sets the number of parallel threads for backup, restore, merge, validate, checkdb, and archive-push processes.

`--progress`

Shows the progress of operations.

`--help`

Shows detailed information about the options that can be used with this command.

Recovery Target Options

If [continuous WAL archiving](#) is configured, you can use one of these options together with [restore](#) or [validate](#) commands to specify the moment up to which the database cluster must be restored or validated.

`--recovery-target=immediate|latest`

Defines when to stop the recovery:

- The `immediate` value stops the recovery after reaching the consistent state of the specified backup, or the latest available backup if the `-i/--backup-id` option is omitted. This is the default behavior for STREAM backups.
- The `latest` value continues the recovery until all WAL segments available in the archive are applied. Setting this value of `--recovery-target` also sets `--recovery-target-timeline` to `latest`.

`--recovery-target-timeline=timeline`

Specifies a particular timeline to be used for recovery:

- `current` — the timeline of the specified backup, default.
- `latest` — the timeline of the latest available backup.
- A numeric value.

`--recovery-target-lsn=lsn`

Specifies the LSN of the write-ahead log location up to which recovery will proceed.

`--recovery-target-name=recovery_target_name`

Specifies a named savepoint up to which to restore the cluster.

`--recovery-target-time=time`

Specifies the timestamp up to which recovery will proceed. If the time zone offset is not specified, the local time zone is used.

Example: `--recovery-target-time="2020-01-01 00:00:00+03"`

`--recovery-target-xid=xid`

Specifies the transaction ID up to which recovery will proceed.

`--recovery-target-inclusive=boolean`

Specifies whether to stop just after the specified recovery target (`true`), or just before the recovery target (`false`). This option can only be used together with `--recovery-target-name`, `--recovery-target-time`, `--recovery-target-lsn` or `--recovery-target-xid` options. The default depends on the [recovery_target_inclusive](#) parameter.

`--recovery-target-action=pause|promote|shutdown`

Specifies [recovery_target_action](#) the server should take when the recovery target is reached.

Default: `pause`

Retention Options

You can use these options together with [backup](#) and [delete](#) commands.

For details on configuring retention policy, see the section [Configuring Retention Policy](#).

`--retention-redundancy=redundancy`

Specifies the number of full backup copies to keep in the data directory. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--retention-window=window`

Number of days of recoverability. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--wal-depth=wal_depth`

Number of latest valid backups on every timeline that must retain the ability to perform PITR. Must be a non-negative integer. The zero value disables this setting.

Default: 0

`--delete-wal`

Deletes WAL files that are no longer required to restore the cluster from any of the existing backups.

`--delete-expired`

Deletes backups that do not conform to the retention policy defined in the `pg_probackup.conf` configuration file.

`--merge-expired`

Merges the oldest incremental backup that satisfies the requirements of retention policy with its parent backups that have already expired.

`--dry-run`

Displays the current status of all the available backups, without deleting or merging expired backups, if any.

Pinning Options

You can use these options together with [backup](#) and [set-backup](#) commands.

For details on backup pinning, see the section [Backup Pinning](#).

`--ttl=ttl`

Specifies the amount of time the backup should be pinned. Must be a non-negative integer. The zero value unpins the already pinned backup. Supported units: ms, s, min, h, d (s by default).

Example: `--ttl=30d`

`--expire-time=time`

Specifies the timestamp up to which the backup will stay pinned. Must be an ISO-8601 complaint timestamp. If the time zone offset is not specified, the local time zone is used.

Example: `--expire-time="2020-01-01 00:00:00+03"`

Logging Options

You can use these options with any command.

`--no-color`

Disable coloring for console log messages of `warning` and `error` levels.

`--log-level-console=log_level`

Controls which message levels are sent to the console log. Valid values are `verbose`, `log`, `info`, `warning`, `error` and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables console logging.

Default: `info`

Note

All console log messages are going to `stderr`, so the output of `show` and `show-config` commands does not mingle with log messages.

`--log-level-file=log_level`

Controls which message levels are sent to a log file. Valid values are `verbose`, `log`, `info`, `warning`, `error`, and `off`. Each level includes all the levels that follow it. The later the level, the fewer messages are sent. The `off` level disables file logging.

Default: `off`

`--log-filename=log_filename`

Defines the filenames of the created log files. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `pg_probackup.log`

For example, if you specify the `pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `pg_probackup-1.log` for Monday, `pg_probackup-2.log` for Tuesday, and so on.

This option takes effect if file logging is enabled by the `--log-level-file` option.

`--error-log-filename=error_log_filename`

Defines the filenames of log files for error messages only. The filenames are treated as a `strftime` pattern, so you can use %-escapes to specify time-varying filenames.

Default: `none`

For example, if you specify the `error-pg_probackup-%u.log` pattern, `pg_probackup` generates a separate log file for each day of the week, with `%u` replaced by the corresponding decimal number: `error-pg_probackup-1.log` for Monday, `error-pg_probackup-2.log` for Tuesday, and so on.

This option is useful for troubleshooting and monitoring.

`--log-directory=log_directory`

Defines the directory in which log files will be created. You must specify the absolute path. This directory is created lazily, when the first log message is written.

Default: `$BACKUP_PATH/log/`

`--log-format-console=log_format`

Defines the format of the console log. Only set from the command line. Note that you cannot specify this option in the `pg_probackup.conf` configuration file through the `set-config` command and that the `backup` command also treats this option specified in the configuration file as an error. Possible values are:

- `plain` — sets the plain-text format of the console log.
- `json` — sets the JSON format of the console log.

Default: `plain`

`--log-format-file=log_format`

Defines the format of log files used. Possible values are:

- `plain` — sets the plain-text format of log files.
- `json` — sets the JSON format of log files.

Default: `plain`

`--log-rotation-size=log_rotation_size`

Maximum size of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The zero value disables size-based rotation. Supported units: kB, MB, GB, TB (kB by default).

Default: 0

`--log-rotation-age=log_rotation_age`

Maximum lifetime of an individual log file. If this value is reached, the log file is rotated once a `pg_probackup` command is launched, except `help` and `version` commands. The time of the last log file creation is stored in `$BACKUP_PATH/log/log_rotation`. The zero value disables time-based rotation. Supported units: ms, s, min, h, d (min by default).

Default: 0

Connection Options

You can use these options together with `backup`, `catchup`, and `checkdb` commands.

All `libpq` environment variables are supported.

`-d dbname`

`--pgdatabase=dbname`

`PGDATABASE`

Specifies the name of the database to connect to. The connection is used only for managing backup process, so you can connect to any existing database. If this option is not provided on the command line, `PGDATABASE` environment variable, or the `pg_probackup.conf` configuration file, `pg_probackup` tries to take this value from the `PGUSER` environment variable, or from the current user name if `PGUSER` variable is not set.

`-h host`

`--pghost=host`

`PGHOST`

Specifies the host name of the system on which the server is running. If the value begins with a slash, it is used as a directory for the Unix domain socket.

Default: `localhost`

`-p port`

`--pgport=port`

`PGPORT`

Specifies the TCP port or the local Unix domain socket file extension on which the server is listening for connections.

Default: 5432

```
-U username
--pguser=username
PGUSER
```

User name to connect as.

```
-w
--no-password
```

Disables a password prompt. If the server requires password authentication and a password is not available by other means such as a [.pgpass](#) file or `PGPASSWORD` environment variable, the connection attempt will fail. This flag can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W
--password
```

Forces a password prompt. (Deprecated)

Compression Options

You can use these options together with [backup](#) and [archive-push](#) commands.

```
--compress-algorithm=compression_algorithm
```

Defines the algorithm to use for compressing data files. Possible values are `zlib`, `lz4`, `zstd`, `pglz`, and `none`. If set to any value, but `none`, this option enables compression that uses the corresponding algorithm. Both data files and WAL files are compressed. By default, compression is disabled. For the [archive-push](#) command, the `pglz` compression algorithm is not supported.

Note

`pg_probackup` supports compression algorithms included in the Postgres Pro version. In particular:

- `lz4` is supported for Postgres Pro Enterprise 13 and higher.
- `zstd` is supported for Postgres Pro Enterprise 11 and higher.

Default: none

```
--compress-level=compression_level
```

Defines the compression level. This option can be used together with the `--compress-algorithm` option. Possible values depend on the compression algorithm specified:

- 0 — 9 for `zlib`
- 1 for `pglz`
- 0 — 12 for `lz4`
- 0 — 22 for `zstd`

The value of 0 sets the default compression level for the specified algorithm:

- 6 for `zlib`
- 1 for `pglz`
- 9 for `lz4`

- 3 for `zstd`

Note

The pure lz4 algorithm has only one compression level — 1. So, if the specified compression algorithm is `lz4` and `--compress-level` is greater than 1, the `lz4hc` algorithm is actually used, which is much slower although does better compression.

Default: 1

`--compress`

Specifies the default compression algorithm and `--compress-level=1`. The default algorithm is selected among those supported by Postgres Pro according to the priorities: `zstd` (highest) -> `lz4` -> `zlib` -> `pglz`. The `--compress` option overrides the `--compression-algorithm` and `--compress-level` settings and cannot be specified together with them.

Archiving Options

These options can be used with the [archive-push](#) command in the `archive_command` setting and the [archive-get](#) command in the `restore_command` setting.

Additionally, [remote mode options](#) and [logging options](#) can be used.

`--wal-file-path=wal_file_path`

Provides the path to the WAL file in `archive_command` and `restore_command`. Use the `%p` variable as the value for this option or explicitly specify the path to a file outside of the data directory. If you skip this option, the path specified in `pg_probackup.conf` will be used.

`--wal-file-name=wal_file_name`

Provides the name of the WAL file in `archive_command` and `restore_command`. Use the `%f` variable as the value for this option for correct processing. If the value of `--wal-file-path` is a path outside of the data directory, explicitly specify the filename.

`--overwrite`

Overwrites archived WAL file. Use this flag together with the [archive-push](#) command if the specified subdirectory of the backup catalog already contains this WAL file and it needs to be replaced with its newer copy. Otherwise, `archive-push` reports that a WAL segment already exists, and aborts the operation. If the file to replace has not changed, `archive-push` skips this file regardless of the `--overwrite` flag.

`--batch-size=batch_size`

Used to speed up archiving in case of `archive-push` or to speed up recovery in case of `archive-get`. Sets the maximum number of WAL files that can be copied into the archive by a single `archive-push` process, or from the archive by a single `archive-get` process.

`--archive-timeout=wait_time`

Sets the timeout for considering existing `.part` files to be stale. By default, `pg_probackup` waits 300 seconds. This option can be used only with [archive-push](#) command.

`--no-ready-rename`

Do not rename status files in the `archive_status` directory. This option should be used only if `archive_command` contains multiple commands. This option can be used only with [archive-push](#) command.

`--no-sync`

Do not sync copied WAL files to disk. You can use this flag to speed up archiving process. Using this flag can result in WAL archive corruption in case of operating system or hardware crash. This option can be used only with [archive-push](#) command.

`--prefetch-dir=path`

Directory used to store prefetched WAL segments if `--batch-size` option is used. Directory must be located on the same filesystem and on the same mountpoint the `PGDATA/pg_wal` is located. By default files are stored in `PGDATA/pg_wal/pbk_prefetch` directory. This option can be used only with [archive-get](#) command.

`--no-validate-wal`

Do not validate prefetched WAL file before using it. Use this option if you want to increase the speed of recovery. This option can be used only with [archive-get](#) command.

Remote Mode Options

This section describes the options related to running `pg_probackup` operations remotely via SSH. These options can be used with [add-instance](#), [set-config](#), [backup](#), [catchup](#), [restore](#), [archive-push](#), and [archive-get](#) commands.

For details on configuring and using the remote mode, see [the section called “Configuring the Remote Mode”](#) and [the section called “Using pg_probackup in the Remote Mode”](#).

`--remote-proto=proto`

Specifies the protocol to use for remote operations. Currently only the SSH protocol is supported. Possible values are:

- `ssh` enables the remote mode via SSH. This is the default value.
- `none` explicitly disables the remote mode.

You can omit this option if the `--remote-host` option is specified.

`--remote-host=destination`

Specifies the remote host IP address or hostname to connect to.

`--remote-port=port`

Specifies the remote host port to connect to.

Default: 22

`--remote-user=username`

Specifies remote host user for SSH connection. If you omit this option, the current user initiating the SSH connection is used.

`--remote-path=path`

Specifies `pg_probackup` installation directory on the remote system.

`--ssh-options=ssh_options`

Provides a string of SSH command-line options. For example, the following options can be used to set `keep-alive` for SSH connections opened by `pg_probackup`: `--ssh-options="-o ServerAliveCountMax=5 -o ServerAliveInterval=60"`. For the full list of possible options, see [ssh_config manual page](#).

Remote WAL Archive Options

This section describes the options used to provide the arguments for [remote mode options](#) in [archive-get](#) used in the [restore_command](#) command when restoring ARCHIVE backups or performing PITR.

`--archive-host=destination`

Provides the argument for the `--remote-host` option in the `archive-get` command.

`--archive-port=port`

Provides the argument for the `--remote-port` option in the `archive-get` command.

Default: 22

`--archive-user=username`

Provides the argument for the `--remote-user` option in the `archive-get` command. If you omit this option, the user that has started the Postgres Pro cluster is used.

Default: Postgres Pro user

Incremental Restore Options

This section describes the options for incremental cluster restore. These options can be used with the `restore` command.

`-I incremental_mode`

`--incremental-mode=incremental_mode`

Specifies the incremental mode to be used. Possible values are:

- `CHECKSUM` — replace only pages with mismatched checksum and LSN.
- `LSN` — replace only pages with LSN greater than point of divergence.
- `NONE` — regular restore.

Partial Restore Options

This section describes the options for partial cluster restore. These options can be used with the `restore` command.

`--db-exclude=dbname`

Specifies the name of the database to exclude from restore. All other databases in the cluster will be restored as usual, including `template0` and `template1`. This option can be specified multiple times for multiple databases.

`--db-include=dbname`

Specifies the name of the database to restore from a backup. All other databases in the cluster will not be restored, with the exception of `template0` and `template1`. This option can be specified multiple times for multiple databases.

S3 Options

This section describes the options needed to store backups in private clouds. These options can be used with any commands that `pg_probackup` runs using S3 interface.

`--s3=s3_interface_provider`

Specifies the S3 interface provider. Possible values are:

- `minio` — MinIO object storage, compatible with S3 cloud storage service. With this provider, custom S3 server settings can be specified. The HTTP protocol, port 9000, and region `us-east-1` are used by default.
- `vk` — VK Cloud storage. With this provider, the S3 host address `hb.vkcs.cloud`, port 443, and HTTPS protocol are only used. Custom values of the host, port, and protocol are ignored. The default value of region is `ru-msk`.
- `aws` — Amazon S3 storage, offered by Amazon Web Services (AWS). With this provider, the S3 host address `bucket_name.s3.region.amazonaws.com`, port 443, and HTTPS protocol are only

used. Custom values of the host, port, and protocol are ignored. The default value of region is `us-east-1`.

With `--s3=minio`, `pg_probackup` will work fine for a VK Cloud storage if the S3 host address, port and protocol are properly specified (host address is `hb.vkcs.cloud` or the one specified in the appropriate section of the VK Cloud profile, port 443, and HTTPS protocol). Do not specify `--s3=minio` for the Amazon S3 storage.

Once a `pg_probackup` command runs with the `--s3` option, `pg_probackup` starts running all commands that support parallel execution on 10 parallel threads (for details, see [the section called “Running pg_probackup on Parallel Threads”](#)). You can change the number of threads using the `-j/--threads` option.

`--s3-config-file=path_to_config_file`

Specifies the S3 configuration file. Settings in the configuration file override the environment variables. If this option is not specified, `pg_probackup` first looks for the S3 configuration file at `/etc/pg_probackup/s3.config` and then at `~postgres/.pg_probackup/s3.config`. The following is an example of the S3 configuration file:

```
access-key = ...
secret-key = ...
s3-host = localhost
s3-port = 9000
s3-bucket = s3demo
s3-region=us-east-1
s3-buffer-size = 32
s3-secure = on | https | http | off
```

Testing and Debugging Options

This section describes options useful only in a test or development environment.

`--cfs-nondatfile-mode`

Instructs [backup](#) command to backup CFS in a legacy mode. This allows fine-tuning compatibility with `pg_probackup` versions earlier than 2.6.0. This option is mainly designed for testing.

`PGPROBACKUP_TESTS_SKIP_HIDDEN`

Instructs `pg_probackup` to ignore backups marked as hidden. Note that `pg_probackup` can never mark a backup as hidden. It can only be done by directly editing the `backup.control` file. This option can only be set with environment variables.

`--destroy-all-other-dbs`

By default, `pg_probackup` exits with an error if an attempt is made to perform a partial incremental restore since this destroys databases not included in the restore set. This flag allows you to suppress the error and proceed with the partial incremental restore (e.g., to keep a development database snapshot up-to-date with a production one). This option can be used with the [restore](#) command.

Important

Never use this flag in a production cluster.

`PGPROBACKUP_TESTS_SKIP_EMPTY_COMMIT`

Instructs `pg_probackup` to skip empty commits after `pg_backup_stop`.

Versioning

`pg_probackup` follows [semantic](#) versioning.

pg_probackup utility is based on pg_arman, which was originally written by NTT and then developed and maintained by Michael Paquier.

pg_repack

pg_repack — utility and Postgres Pro Enterprise extension to reorganize tables

Synopsis

```
pg_repack [option...] [dbname]
```

Description

[pg_repack](#) is a Postgres Pro Enterprise extension which lets you remove bloat from tables and indexes, and optionally restore the physical order of clustered indexes. Unlike [CLUSTER](#) and `VACUUM FULL` it works online, without holding an exclusive lock on the processed tables during processing. `pg_repack` is efficient to boot, with performance comparable to using `CLUSTER` directly.

`pg_repack` is a fork of the previous https://github.com/reorg/pg_reorg project.

You can choose one of the following methods to reorganize data:

- Online `CLUSTER` (ordered by cluster index)
- Ordering by specified columns
- Online `VACUUM FULL` (packing rows only)
- Rebuild or relocate only the indexes of a table

Note

Only superusers can use the utility.

Note

Target table must have a PRIMARY KEY, or at least a UNIQUE total index on a NOT NULL column.

Installation

On Linux systems, `pg_repack` is provided together with Postgres Pro as a separate pre-built package and requires the `postgrespro-ent-13-server` package to be installed with all the dependencies. For the list of available packages and detailed installation instructions, see [Chapter 17](#). On Windows systems, `pg_repack` is automatically installed as part of Postgres Pro.

Once you have `pg_repack` installed, load the `pg_repack` extension in the database you want to process, as follows:

```
$ psql -c "CREATE EXTENSION pg_repack" -d your_database
```

You can later remove `pg_repack` from a Postgres Pro installation using `DROP EXTENSION pg_repack`.

If you are upgrading from a previous version of `pg_repack`, just drop the old version from the database as explained above and install the new version.

Options

Reorganization Options

```
-a  
--all
```

Attempt to repack all the databases of the cluster. Databases where the `pg_repack` extension is not installed will be skipped.

`-t table`
`--table=table`

Reorganize the specified table(s) only. Multiple tables may be reorganized by writing multiple `-t` switches. By default, all eligible tables in the target databases are reorganized.

`-c schema`
`--schema=schema`

Repack the tables in the specified schema(s) only. Multiple schemas may be repacked by writing multiple `-c` switches. Can be used in conjunction with `--tablespace` to move tables to a different tablespace.

`-o column[, ...]`
`--order-by=column[, ...]`

Perform an online `CLUSTER` ordered by the specified columns.

`-n`
`--no-order`

Perform an online `VACUUM FULL`. Since version 1.2 this is the default for non-clustered tables.

`-N`
`--dry-run`

Show what would be repacked and exit.

`-j num_jobs`
`--jobs=num_jobs`

Create the specified number of extra connections to Postgres Pro, and use these extra connections to parallelize the rebuild of indexes on each table. Parallel index builds are only supported for full-table repacks, not with `--index` or `--only-indexes` options. If your server has extra cores and disk I/O available, this can be a useful way to speed up `pg_repack`.

`-s tablespace`
`--tablespace=tablespace`

Move the repacked tables to the specified tablespace: essentially an online version of `ALTER TABLE ... SET TABLESPACE`. The tables' indexes are left in the original tablespace unless `--moveidx` is specified too.

`-S`
`--moveidx`

Also move the indexes of the repacked tables to the tablespace specified by the `--tablespace` option.

`-i index`
`--index=index`

Repack the specified index(es) only. Multiple indexes may be repacked by writing multiple `-i` switches. May be used in conjunction with `--tablespace` to move the index(es) to a different tablespace.

`-x`
`--only-indexes`

Repack only the indexes of the specified table(s), which must be specified with the `--table` option.

`-T secs`
`--wait-timeout=secs`

`pg_repack` needs to take an exclusive lock at the end of the reorganization. This setting controls how many seconds `pg_repack` will wait to acquire this lock. If the lock cannot be taken after this duration,

`pg_repack` will forcibly cancel the conflicting queries. If you are using Postgres Pro or PostgreSQL version 8.4 or newer, `pg_repack` will fall back to using `pg_terminate_backend()` to disconnect any remaining backends after this timeout has passed twice. The default is 60 seconds.

`-Z`
`--no-analyze`

Disable `ANALYZE` after a full-table reorganization. If not specified, `ANALYZE` is executed after the reorganization.

Connection Options

`[-d] dbname`
`[--dbname=] dbname`

Specifies the name of the database to be reorganized. If this is not specified and `-a` (or `--all`) is not used, the database name is read from the environment variable `PGDATABASE`. If that is not set, the user name specified for the connection is used.

`-h host`
`--host=host`

Specifies the host name of the machine on which the server is running. If the value begins with a slash, it is used as the directory for the Unix domain socket.

`-p port`
`--port=port`

Specifies the TCP port or local Unix domain socket file extension on which the server is listening for connections.

`-U username`
`--username=username`

User name to connect as.

`-w`
`--no-password`

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

`-W`
`--password`

Force `pg_repack` to prompt for a password before connecting to a database.

This option is never essential, since `pg_repack` will automatically prompt for a password if the server demands password authentication. However, `pg_repack` will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Generic Options

`-e`
`--echo`

Echo the commands that `pg_repack` generates and sends to the server.

`-E level`
`--elevel=level`

Choose the output message level from `DEBUG`, `INFO`, `NOTICE`, `WARNING`, `ERROR`, `LOG`, `FATAL`, and `PANIC`. The default is `INFO`.

`--help`

Show help about `pg_repack` command line arguments, and exit.

`-V`

`--version`

Print the `pg_repack` version and exit.

Environment

`PGDATABASE`

`PGHOST`

`PGPORT`

`PGUSER`

Default connection parameters

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by `libpq` (see [Section 35.14](#)).

Examples

Perform an online `CLUSTER` of all the clustered tables in the database `test`, and perform an online `VACUUM FULL` of all the non-clustered tables:

```
$ pg_repack test
```

Perform an online `VACUUM FULL` on the tables `foo` and `bar` in the database `test` (an eventual cluster index is ignored):

```
$ pg_repack --no-order --table foo --table bar test
```

Move all indexes of table `foo` to tablespace `tbs`:

```
$ pg_repack -d test --table foo --only-indexes --tablespace tbs
```

Move the specified index to tablespace `tbs`:

```
$ pg_repack -d test --index idx --tablespace tbs
```

Diagnostics

Error messages are reported when `pg_repack` fails. The following list shows the cause of errors.

You need to cleanup by hand after fatal errors. To cleanup, just remove `pg_repack` from the database and install it again.

For Postgres Pro or PostgreSQL 9.1 and newer execute:

```
DROP EXTENSION pg_repack CASCADE
```

in the database where the error occurred, followed by

```
CREATE EXTENSION pg_repack
```

For previous versions load the script `$SHAREDIR/contrib/uninstall_pg_repack.sql` into the database where the error occurred and then load `$SHAREDIR/contrib/pg_repack.sql` again.

```
INFO: database "db" skipped:
```

```
pg_repack VER is not installed in the database:
```

```
pg_repack is not installed in the database when the --all option is specified.
```

Create the `pg_repack` extension in the database.

```
ERROR: pg_repack VER is not installed in the database:
pg_repack is not installed in the database specified by --dbname
```

Create the `pg_repack` extension in the database.

```
ERROR: program 'pg_repack V1' does not match database library 'pg_repack V2':
There is a mismatch between the pg_repack binary and the database library
(.so or .dll).
```

The mismatch could be due to the wrong binary in the `PATH` or the wrong database being addressed. Check the program directory and the database; if they are what expected you may need to repeat `pg_repack` installation.

```
ERROR: extension 'pg_repack V1' required, found 'pg_repack V2':
The SQL extension found in the database does not match the version required by the
pg_repack program.
```

You should drop the extension from the database and reload it as described in [the section called “Installation”](#).

```
ERROR: relation "table" must have a primary key or not-null unique keys:
The target table doesn't have a PRIMARY KEY or any UNIQUE constraints defined.
```

Define a `PRIMARY KEY` or a `UNIQUE` constraint on the table.

```
ERROR: query failed: ERROR: column "col" does not exist:
The target table doesn't have columns specified by --order-by option.
```

Specify existing columns.

```
WARNING: the table "tbl" already has a trigger called z_repack_trigger:
The trigger was probably installed during a previous attempt
to run pg_repack on the table which was interrupted
and for some reason failed to clean up the temporary objects.
```

You can remove all the temporary objects by dropping and re-creating the extension: see [the section called “Installation”](#) for the details.

```
WARNING: trigger "trg" conflicting on table "tbl":
The target table has a trigger whose name follows z_repack_trigger
in alphabetical order.
```

The `z_repack_trigger` should be the last `BEFORE` trigger to fire. Please rename your trigger so that it sorts alphabetically before `pg_repack` one; you can use:

```
ALTER TRIGGER zzz_my_trigger
ON sometable RENAME TO yyy_my_trigger;
```

ERROR: Another `pg_repack` command may be running on the table. Please try again later.

There is a chance of deadlock when two concurrent `pg_repack` commands are run on the same table. So, try to run the command after some time.

WARNING: Cannot create index "schema"."index_xxxxx", already exists
DETAIL: An invalid index may have been left behind by a previous `pg_repack` on the table which was interrupted. Please use `DROP INDEX "schema"."index_xxxxx"` to remove this index and try again.

A temporary index apparently created by `pg_repack` has been left behind, and we do not want to risk dropping this index ourselves. If the index was in fact created by an old `pg_repack` job which didn't get cleaned up, you should just use `DROP INDEX` and try the `repack` command again.

Restrictions

`pg_repack` comes with the following restrictions.

Temporary tables

`pg_repack` cannot reorganize temporary tables.

GiST indexes

`pg_repack` cannot cluster tables by GiST indexes.

DDL commands

You will not be able to perform DDL commands of the target table(s) *except* `VACUUM` or `ANALYZE` while `pg_repack` is working. `pg_repack` will hold an `ACCESS SHARE` lock on the target table during a full-table repack, to enforce this restriction.

If you are using version 1.1.8 or earlier, you must not attempt to perform any DDL commands on the target table(s) while `pg_repack` is running. In many cases `pg_repack` would fail and rollback correctly, but there were some cases in these earlier versions which could result in data corruption.

[clusterdb](#), [vacuumdb](#)

vacuumlo

`vacuumlo` — remove orphaned large objects from a Postgres Pro database

Synopsis

```
vacuumlo [option...] dbname...
```

Description

`vacuumlo` is a simple utility program that will remove any “orphaned” large objects from a Postgres Pro database. An orphaned large object (LO) is considered to be any LO whose OID does not appear in any `oid` or `lo` data column of the database.

If you use this, you may also be interested in the `lo_manage` trigger in the [lo](#) module. `lo_manage` is useful to try to avoid creating orphaned LOs in the first place.

All databases named on the command line are processed.

Options

`vacuumlo` accepts the following command-line arguments:

```
-l limit  
--limit=limit
```

Remove no more than *limit* large objects per transaction (default 1000). Since the server acquires a lock per LO removed, removing too many LOs in one transaction risks exceeding [max_locks_per_transaction](#). Set the limit to zero if you want all removals done in a single transaction.

```
-n  
--dry-run
```

Don't remove anything, just show what would be done.

```
-v  
--verbose
```

Write a lot of progress messages.

```
-V  
--version
```

Print the `vacuumlo` version and exit.

```
-?  
--help
```

Show help about `vacuumlo` command line arguments, and exit.

`vacuumlo` also accepts the following command-line arguments for connection parameters:

```
-h host  
--host=host
```

Database server's host.

```
-p port  
--port=port
```

Database server's port.

```
-U username  
--username=username
```

User name to connect as.

```
-w  
--no-password
```

Never issue a password prompt. If the server requires password authentication and a password is not available by other means such as a `.pgpass` file, the connection attempt will fail. This option can be useful in batch jobs and scripts where no user is present to enter a password.

```
-W  
--password
```

Force vacuumlo to prompt for a password before connecting to a database.

This option is never essential, since vacuumlo will automatically prompt for a password if the server demands password authentication. However, vacuumlo will waste a connection attempt finding out that the server wants a password. In some cases it is worth typing `-w` to avoid the extra connection attempt.

Environment

```
PGHOST  
PGPORT  
PGUSER
```

Default connection parameters.

This utility, like most other Postgres Pro utilities, also uses the environment variables supported by libpq (see [Section 35.14](#)).

The environment variable `PG_COLOR` specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

Notes

vacuumlo works by the following method: First, vacuumlo builds a temporary table which contains all of the OIDs of the large objects in the selected database. It then scans through all columns in the database that are of type `oid` or `lo`, and removes matching entries from the temporary table. (Note: Only types with these names are considered; in particular, domains over them are not considered.) The remaining entries in the temporary table identify orphaned LOs. These are removed.

G.2. Server Applications

This section covers Postgres Pro Enterprise server-related applications. They are typically run on the host where the database server resides. See also [Postgres Pro Server Applications](#) for information about server applications that are part of the core Postgres Pro Enterprise distribution.

mamonsu

mamonsu — a monitoring agent for collecting Postgres Pro and system metrics

Synopsis

```
mamonsu agent [agent_action]

mamonsu bootstrap -M mamonsu_user [-c | --config] [-x | --create-extensions] [connection_options]

mamonsu export {template | config} filename [export_options]

mamonsu report [report_options] [connection_options]

mamonsu tune [tuning_options] [connection_options]

mamonsu upload [upload_options]

mamonsu zabbix dashboard upload template_name

mamonsu zabbix {template | host | hostgroup} server_action

mamonsu zabbix item {error | lastvalue | lastclock} host_id

mamonsu zabbix version

mamonsu [-c | --config] [-d | --daemonize]

mamonsu --version

mamonsu --help
```

Description

mamonsu is a monitoring agent for collecting Postgres Pro and system metrics that can be visualized on the Zabbix server. Unlike the native Zabbix Agent configured to collect Postgres Pro metrics, mamonsu uses a single database connection, which allows to minimize performance impact on the monitored system.

The mamonsu agent includes the following components:

- A supervisor process that monitors database and system activity.
- Plugins that specify which Postgres Pro and system metrics to collect.
- Customizable configuration and template files that define which plugins to use and how to visualize the collected data.

mamonsu is an active agent, which means that it sends the data to the Zabbix server once it is collected. Pre-configured to monitor multiple Postgres Pro and system metrics out of the box, mamonsu can be extended with your own custom plugins to track other metrics critical for your system.

mamonsu also provides the command-line interface for updating some Zabbix server settings, as well as getting an overview of the monitored system configuration and tuning Postgres Pro and system settings on the fly. You can find the list of all mamonsu commands in [the section called “Command-Line Reference”](#).

Installation and Setup

Important

Before you start installation, attentively read [Compatibility Considerations](#).

To use mamonsu, you must create a Zabbix account and set up a Zabbix server as explained in [Zabbix documentation](#). Naturally, you must also have a Postgres Pro instance up and running if you are going to monitor Postgres Pro metrics. If you are configuring your Postgres Pro cluster from scratch, see [Chapter 17](#) and [Section 18.2](#) for Postgres Pro installation and setup instructions, respectively.

Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

A pre-built mamonsu package is provided together with Postgres Pro Enterprise, but has a separate installer. Once you have installed mamonsu, complete the following steps to set up metrics collection:

1. Optionally, bootstrap mamonsu

If you omit this step, metrics can only be collected on behalf of a superuser, which is not recommended.

In this step, the `bootstrap` command sets the mamonsu user, creates `mamonsu` schema in the specified or implied database, as well as extensions and objects needed for monitoring.

`bootstrap` has no mandatory options. When run without options, it takes the values needed from the configuration file (`/etc/mamonsu/agent.conf` by default). Below is a simple example of bootstrap:

1. In the `[postgres]` section of `agent.conf`, specify connection parameters for the Postgres Pro cluster you are going to monitor. For more details, see [Connection Parameters](#).
2. Run the following command to bootstrap mamonsu:

```
mamonsu bootstrap
```

This command will create the user `mamonsu` with the password `mamonsu`, create monitoring functions in the database specified in `agent.conf` and grant the right to execute them to the `mamonsu` user.

In the following example, `bootstrap` options are passed explicitly.

1. Create a non-privileged database user for mamonsu. For example:

```
CREATE USER mamonsu_user WITH PASSWORD 'mamonsu_password';
GRANT pg_monitor TO mamonsu_user;
```

2. Create a database that will be used for connection to Postgres Pro. For example:

```
CREATE DATABASE mamonsu_database OWNER mamonsu_user;
```

3. Run the following command to bootstrap mamonsu:

```
mamonsu bootstrap -M mamonsu_user -x -c /etc/mamonsu/agent.conf -d
mamonsu_database -U postgres --host myhost --port 5432
```

For details of the options `-M`, `-x` and `-c`, see [bootstrap](#). For details of other options, see [Connection Options](#). This command will create monitoring functions in the `mamonsu_database` and grant the right to execute them to `mamonsu_user`. The `pg_buffercache` extension will also be created to

ensure collection of metrics on the shared buffer cache, and the path to the configuration file will be changed.

As a result, a superuser connection is no longer required. Note that mamonsu also creates several tables in the `mamonsu` schema in the specified database. Do not delete these tables as they are required for mamonsu to work.

2. Configure mamonsu

Edit the `agent.conf` configuration file, which is located in the `/etc/mamonsu/` directory by default.

- Configure Zabbix-related settings. The `address` field must point to the running Zabbix server, while the `client` field must provide the name of the Zabbix host. You can find the list of hosts available for your account in the Zabbix web interface under **Configuration > Hosts**.

```
[zabbix]
; enabled by default
enabled = True
client = zabbix_host_name
address = zabbix_server
```

- By default, mamonsu will collect both Postgres Pro and system metrics. If required, you can disable metrics collection of either type by setting the `enabled` parameter to `False` in the `[postgres]` or `[system]` section of the `agent.conf` file, respectively.

```
[system]
; enabled by default
enabled = True
```

Note

While mamonsu can collect Postgres Pro metrics from a remote cluster, system metrics are only collected locally. If you choose to collect Postgres Pro metrics remotely, make sure to disable collection of system metrics to avoid confusion, as they will be displayed under the same host in Zabbix.

- If you are going to collect Postgres Pro metrics, specify connection parameters for the Postgres Pro cluster you are going to monitor. In the `user`, `password`, and `database` fields, you must specify the `mamonsu_user`, `mamonsu_password`, and the `mamonsu_database` used for bootstrap, respectively. If you skipped the bootstrap, specify superuser credentials and the database to connect to.

```
[postgres]
; enabled by default
enabled = True
user = mamonsu_user
database = mamonsu_database
password = mamonsu_password
port = 5432
```

These are the main mamonsu settings to get started. You can also fine-tune other mamonsu settings as explained in [the section called “Configuration Parameters”](#).

3. Configure how to display metrics on the Zabbix server

1. Generate a template that defines how to visualize the collected metrics on the Zabbix server:

```
mamonsu export template template.xml
```

mamonsu generates the `template.xml` file in your current directory. By default, the name of the template that will be displayed in the Zabbix account is `PostgresPro-OS`, where `OS` is the name

of your operating system. To get a template with a different display name, you can run the above command with the `--template-name` option.

2. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:

- Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
- Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

3. Upload `template.xml` to the Zabbix server.

```
mamonsu zabbix template export template.xml
```

Alternatively, you can upload the template through the Zabbix web interface: log in to your Zabbix account and select **Templates > Import**.

4. Link the generated template to the host to be monitored.

In the Zabbix web interface, select your host, go to **Templates > Add**, select your template, and click **Update**.

Tip

If you would like to link a template with a new Zabbix host, you can do it from the command line using `mamonsu zabbix` commands. See [the section called “Managing Zabbix Server Settings from the Command Line”](#) for details.

When the setup is complete, start `mamonsu`. For example, on Linux systems, you can start `mamonsu` as a service with the following command:

```
service mamonsu start
```

`mamonsu` picks up all the parameters from the `mamonsu` configuration file and starts monitoring your system.

Command-Line Reference

agent

Syntax:

```
mamonsu agent { metric-list | metric-get metric_name | version }
```

Provide information on the collected metrics from the command line. You can specify one of the following parameters:

`metric-list`

Show the list of metrics that `mamonsu` is collecting. The output of this command provides the item key of each metric, its latest value, and the time when this value was received.

`metric-get metric_name`

Check the latest value for the specified metric. You can get the list of available metrics using the `metric-list` option.

`version`

Display `mamonsu` version.

bootstrap

Syntax:

```
mamonsu bootstrap -M mamonsu_user
                    [-c config_file] | --config[=config_file]
                    [-x | --create-extensions] [connection_options]
```

Bootstrap mamonsu. This command can take the following options:

-M
Specify a non-privileged user that will own all mamonsu processes.

-c *config_file*
--config=*config_file*
Specify the `agent.conf` file where the `[postgres]` section contains the database name to be used if `--dbname` is not specified through *connection_options*.

Default: `/etc/mamonsu/agent.conf`

-x
--create-extensions
Create auxiliary extensions. The `pg_buffercache` extension will be created, which is no longer created by default. For Postgres Pro 12 or higher, the `bootstrap -x` command will also create functions to work with the `pgpro_stats` extension and grant the right to execute them to the `mamonsu` user.

connection_options
Provide optional *command-line connection parameters*.

export

Syntax:

```
mamonsu export config filename.conf  [--add-plugins=plugin_directory]
mamonsu export template filename.xml  [--add-plugins=plugin_directory]
                                         [--template-name=template_name]
                                         [--application=application_name]
                                         [--old-zabbix]
```

Generate a template or configuration file for metrics collection. The optional parameters to customize metrics collection are as follows:

--add-plugins=*plugin_directory*
Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

--template-name=*template_name*
Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

--application=*application_name*
Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

--old-zabbix
Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

export zabbix-parameters

Syntax:

```
mamonsu export zabbix-parameters filename.conf [--add-plugins=plugin_directory]
                                         [--plugin-type={pg | sys | all}]
                                         [--pg-version=version]
                                         [--config=config_file]
```

Export metrics configuration for use with the native [Zabbix agent](#). The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` for Postgres Pro metrics.
- `sys` for system metrics.
- `all` for both Postgres Pro and system metrics.

Default: `all`

`--pg-version=version`

Specify the major version of the server for which to configure metrics collection. `mamonsu` can collect metrics for all supported Postgres Pro versions, as well as PostgreSQL versions starting from 9.5.

Default: `10`

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

export zabbix-template

Syntax:

```
mamonsu export zabbix-template filename.conf [--add-plugins=plugin_directory]
                                         [--plugin-type={pg | sys | all}]
                                         [--template-name=template_name]
                                         [--application=application_name]
                                         [--config=config_file]
                                         [--old-zabbix]
```

Export a template for use with the native Zabbix agent. The optional parameters to customize metrics collection are as follows:

`--add-plugins=plugin_directory`

Collect metrics that are defined in custom plugins located in the specified *plugin_directory*. If you are going to use custom plugins, you must provide this option when generating both the configuration file and the template.

`--plugin-type={pg | sys | all}`

Specify the type of metrics to collect:

- `pg` configures Postgres Pro metrics.
- `sys` configures system metrics.
- `all` configures both Postgres Pro and system metrics.

Default: `all`

`--template-name=template_name`

Specify the name of the template that will be displayed on the Zabbix server.

Default: `PostgresPro-OS`, where *OS* is the name of your operating system

`--application=application_name`

Specify an identifier under which the collected metrics will be displayed on the Zabbix server.

Default: `App-PostgresPro-OS`, where *OS* is the name of your operating system

`--config=config_file`

Specify the `agent.conf` file to be used as the source for metrics definitions.

Default: `/etc/mamonsu/agent.conf`

`--old-zabbix`

Export a template for Zabbix server version 4.2 or lower. By default, the template is generated in a format compatible with Zabbix 4.4 or higher.

report

Syntax:

```
mamonsu report [--run-system=Boolean] [--run-postgres=Boolean]
               [--print-report=Boolean] [--report-path=report_file]
               [--disable-sudo] [connection_options]
```

Generate a detailed report on the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration.

The following optional parameters customize the report:

`--run-system=Boolean`

Include system information into the generated report.

Default: `True`

`--run-postgres=Boolean`

Include information on Postgres Pro into the generated report.

Default: `True`

`--print-report=Boolean`

Print the report to stdout.

Default: `True`

`--report-path=report_file`

Save the report into the specified file.

Default: `/tmp/report.txt`

`--disable-sudo`

Do not report data that can only be received with superuser rights. This option is only available for Linux systems.

connection_options

Provide optional *command-line connection parameters*.

tune

Syntax:

```
mamonsu tune [--dry-run] [--disable-sudo] [--log-level {INFO|DEBUG|WARN}]
             [--dont-tune-pgbadger] [--dont-reload-postgresql]
             [connection_options]
```

Optimize Postgres Pro and system configuration based on the collected statistics. You can use the following options:

`--dry-run`

Display the settings to be tuned without changing the actual system and Postgres Pro configuration.

`--disable-sudo`

Do not tune the settings that can only be changed by a superuser. This option is only available for Linux systems.

`--dont-tune-pgbadger`

Do not tune *pgbadger* parameters.

`--log-level { INFO | DEBUG | WARN }`

Change the logging level.

Default: INFO

`--dont-reload-postgresql`

Forbid mamonsu to run the `pg_reload_conf()` function. If you specify this option, the modified settings that require reloading Postgres Pro configuration do not take effect immediately.

connection_options

Provide optional *command-line connection parameters*.

upload

Syntax:

```
mamonsu upload [--zabbix-file=metrics_file]
               [--zabbix-address=zabbix_address] [--zabbix-port=port_number]
               [--zabbix-client=zabbix_host_name] [--zabbix-log-level={INFO|DEBUG|
WARN}]
```

Upload metrics data previously saved into a file onto a Zabbix server for visualization. For details on how to save metrics into a file, see [the section called “Logging Parameters”](#).

This command can take the following options:

`--zabbix-address=zabbix_address`

The address of the Zabbix server.

Default: localhost

`--zabbix-port=port_number`

The port of the Zabbix server.

Default: 10051

`--zabbix-file=metrics_file`

A text file that stores the collected metrics data to be visualized, such as `localhost.log`.

`--zabbix-client=zabbix_host_name`

The name of the Zabbix host.

Default: `localhost`

`--zabbix-log-level={INFO|DEBUG|WARN}`

Change the logging level.

Default: `INFO`

zabbix dashboard upload

Syntax:

`mamonsu dashboard upload template_name`

Upload a Zabbix dashboard with the mamonsu metrics to a template on the Zabbix server version 6.0 or higher.

zabbix item

Syntax:

`mamonsu zabbix item {error | lastvalue | lastclock } host_name`

View the specified property of the latest metrics data received by Zabbix for the specified host.

zabbix version

Syntax:

`mamonsu zabbix version`

Get the version of the Zabbix server that mamonsu is connected to.

zabbix host

Syntax:

`mamonsu zabbix host list`

`mamonsu zabbix host show host_name`

`mamonsu zabbix host id host_name`

`mamonsu zabbix host delete host_id`

`mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address`

`mamonsu zabbix host info {templates | hostgroups | graphs | items} host_id`

Manage Zabbix hosts using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix hostgroup

Syntax:

`mamonsu zabbix hostgroup list`

`mamonsu zabbix hostgroup show hostgroup_name`

`mamonsu zabbix hostgroup id hostgroup_name`

```
mamonsu zabbix hostgroup delete hostgroup_id
mamonsu zabbix hostgroup create hostgroup_name
```

Manage Zabbix host groups using one of the actions described in [the section called “Zabbix Server Actions”](#).

zabbix template

Syntax:

```
mamonsu zabbix template list
mamonsu zabbix template show template_name
mamonsu zabbix template id template_name
mamonsu zabbix template delete template_id
mamonsu zabbix template export file
```

Manage Zabbix templates using one of the actions described in [the section called “Zabbix Server Actions”](#).

[--config] [--daemonize]

Syntax:

```
mamonsu [-c config_file | --config=config_file]
        [-d | --daemonize]
```

Start working as a monitoring agent in the foreground or in the background using configuration parameters loaded from the configuration file. If the specified or default configuration file does not exist, exit with an error. Useful for debugging. You can specify the following options:

```
-c config_file
--config=config_file
```

Specify the `agent.conf` file where to load the configuration parameters from.

Default: `/etc/mamonsu/agent.conf`

```
-d
--daemonize
```

Run in the background. Without it, mamonsu will run in the foreground.

--version

Syntax:

```
mamonsu --version
```

Display mamonsu version.

--help

Syntax:

```
mamonsu --help
```

Display mamonsu command-line help.

Connection Options

connection_options provide command-line connection parameters for the target Postgres Pro cluster. *connection_options* can be `--host`, `--port`, `--dbname (-d)`, `--username (-U)`, and `--password (-W)`. The `--dbname` option should specify the *mamonsu_database* created for monitoring purposes. Note that the `--username (-U)` option must specify a superuser that can access the cluster.

If you omit *connection_options*, mamonsu checks the configuration file for the needed settings.

Zabbix Server Actions

Using `mamonsu`, you can control some of the Zabbix server functionality from the command line. Specifically, you can create or delete Zabbix hosts and host groups, as well as generate, import, and delete Zabbix templates using one of the following commands. The *object_name* to use must correspond to the type of the Zabbix object specified in the command: `template`, `host`, or `hostgroup`.

`list`

Display the list of available templates, hosts, or host groups.

`show object_name`

Display the details about the specified template, host, or host group.

`id object_name`

Show the ID of the specified object, which is assigned automatically by the Zabbix server.

`delete object_id`

Delete the object with the specified ID.

`create hostgroup_name`

`create host_name hostgroup_id template_id mamonsu_address`

Create a new host or a host group.

`export template_name`

Generate a Zabbix template.

`info {templates | hostgroups | graphs | items} host_id`

Display detailed information about the templates, host groups, graphs, and metrics available on the host with the specified ID.

Configuration Parameters

The `agent.conf` configuration file is located in the `/etc/mamonsu` directory by default. It provides several groups of parameters that control which metrics to collect and how to log the collected data:

- [connection parameters](#)
- [logging parameters](#)
- [plugin parameters](#)

All parameters must be specified in the `parameter = value` format.

Connection Parameters

[postgres]

The `[postgres]` section controls Postgres Pro metrics collection and can contain the following parameters:

`enabled`

Enables/disables Postgres Pro metrics collection if set to `True` or `False`, respectively.

Default: `True`

`user`

The user on behalf of which the cluster will be monitored. It must be the `mamonsu` user set in `bootstrap`, or a superuser if `bootstrap` was not run.

Default: postgres

password

The password for the specified user.

database

The database to connect to for metrics collection.

Default: postgres

host

The server address to connect to.

Default: localhost

port

The port to connect to.

Default: 5432

application_name

Application name that identifies mamonsu connected to the Postgres Pro cluster.

Default: mamonsu

query_timeout

[statement_timeout](#) for the mamonsu session, in seconds. If a Postgres Pro metric query does not complete within this time interval, it gets terminated.

Default: 10

[system]

The [system] section controls system metrics collection and can contain the following parameters:

enabled

Enables/disables system metrics collection if set to `True` or `False`, respectively.

Default: `True`

[zabbix]

The [zabbix] section provides connection settings for the Zabbix server and can contain the following parameters:

enabled

Enables/disables sending the collected metrics data to the Zabbix server if set to `True` or `False`, respectively.

Default: `True`

client

The name of the Zabbix host.

address

The address of the Zabbix server.

Default: 127.0.0.1

port

The port of the Zabbix server.

Default: 10051

timeout

Maximum time to wait while connecting to the Zabbix server, in seconds.

Default: 15

[agent]

The [agent] section specifies the location of mamonsu and whether it is allowed to access metrics from the command line:

enabled

Enables/disables metrics collection from the command line using the agent command.

Default: True

host

The address of the system on which mamonsu is running.

Default: 127.0.0.1

port

The port on which mamonsu is running.

Default: 10052

[sender]

The [sender] section controls the queue size of the data to be sent to the Zabbix server:

queue

The maximum number of collected metric values that can be accumulated locally before mamonsu sends them to the Zabbix server. Once the accumulated data is sent, the queue is cleared.

Default: 2048

Logging Parameters

[metric_log]

The [metric_log] section enables storing the collected metrics data in text files locally. This section can contain the following parameters:

enabled

Enables/disables storing the collected metrics data in a text file. If this option is set to True, mamonsu creates the localhost.log file for storing metric values.

Default: False

directory

Specifies the directory where log files with metrics data will be stored.

Default: /var/log/mamonsu

max_size_mb

The maximum size of a log file, in MB. When the specified size is reached, it is renamed to localhost.log.archive, and an empty localhost.log file is created.

Default: 1024

[log]

The [log] section specifies logging settings for mamonsu and can contain the following parameters:

file

Specifies the log filename, which can be preceded by the full path.

level

Specifies the debug level. This option can take `DEBUG`, `ERROR`, or `INFO` values.

Default: `INFO`

format

The format of the logged data.

Default: `[% (levelname)s] %(asctime)s - %(name)s - %(message)s`

where `levelname` is the debug level, `asctime` returns the current time, `name` specifies the plugin that emitted this log entry or `root` otherwise, and `message` provides the actual log message.

Plugin Parameters

[plugins]

The [plugins] section specifies custom plugins to be added for metrics collection and can contain the following parameters:

enabled

Enables/disables using custom plugins for metrics collection if set to `True` or `False`, respectively.

Default: `False`

directory

Specifies the directory that contains custom plugins for metrics collection. Setting this parameter to `None` forbids using custom plugins.

Default: `/etc/mamonsu/plugins`

If you need to configure any of the plugins you add to mamonsu after installation, you have to add this plugin section to the `agent.conf` file.

The syntax of this section should follow the syntax used with the examples shown below in [the section called “Individual Plugin Sections”](#).

Individual Plugin Sections

All built-in plugins are installed along with mamonsu. To configure a built-in plugin you should find a corresponding section below the Individual Plugin Sections heading and edit its parameter values:

enabled

Enables/disables using built-in plugins if set to `True` or `False`, respectively. These values are case-sensitive.

Default: `False`

interval

Specifies the plugin operation interval, in seconds. The parameter is set with an integer specifying the plugin operation interval in seconds. You can set different intervals for different plugins. For plugins

that collect PostgreSQL/ Postgres Pro metrics, for example, autovacuum, checkpoint, etc., this is the interval within which mamonsu accesses the Postgres Pro instance for metrics collection. For system plugins, for example, diskstats, memory, etc., this is the interval within which the operating system is accessed. For service plugins, for example, agentapi, logsender, zbxsender, this is the interval within which their functions are called. Note that the `interval` parameter of the `zbxsender` plugin is associated with the `timeout` parameter of the `[zabbix]` section. The maximum Zabbix server response timeout greater than the plugin operation interval may cause misbehavior of the `zbxsender` plugin: the plugin restarts with an error message if the connection or data transfer require longer time than the value specified in the `interval` parameter.

Default: 60

The example below shows individual plugin sections corresponding to the `preparedtransaction` and the `pgprobackup` built-in plugins:

```
[preparedtransaction]
max_prepared_transaction_time = 60
interval = 60

[pgprobackup]
enabled = false
interval = 300
backup_dirs = /backup_dir1,/backup_dir2
pg_probackup_path = /usr/bin/pg_probackup-11
```

[preparedtransaction]

This plugin gets age in seconds of the oldest prepared transaction and number of all transactions prepared for a two-phase commit. For additional information refer to [PREPARE TRANSACTION](#) and [Section 53.80](#).

The `max_prepared_transaction_time` parameter specifies the threshold in seconds for the age of the prepared transaction.

The plugin collects two metrics: `pgsql.prepared.count` (number of prepared transactions) and `pgsql.prepared.oldest` (oldest prepared transaction age in seconds).

If `pgsql.prepared.oldest` value exceeds the threshold specified by the `max_prepared_transaction_time` parameter, a trigger with the following message is fired: "PostgreSQL prepared transaction is too old on {host}".

[pgprobackup]

This plugin uses [pg_probackup](#) to track its backups' state and gets size of backup directories which store all backup files.

Please note that this plugin counts the total size of all files in the target directory. Make sure that extraneous files are not stored in this directory.

The `backup_dirs` parameter specifies a comma-separated list of paths to directories for which metrics should be collected.

The `pg_probackup_path` parameter specifies the path to `pg_probackup`.

By default this plugin is disabled. To enable it set the `enabled` parameter to `True`.

This plugin collects two metrics: `pg_probackup.dir.size[#backup_directory]` (the size of the target directory) and `pg_probackup.dir.error[#backup_directory]` (backup errors) for each specified `backup_directory`.

If any generated backup has bad status, like `ERROR`, `CORRUPT`, `ORPHAN`, a trigger is fired.

Usage

Collecting and Viewing Metrics Data

Once started, mamonsu begins collecting system and Postgres Pro metrics. The `agent` command enables you to get an overview of the collected metrics from the command line in real time.

To view the list of available metrics, use the `agent metric-list` command:

```
mamonsu agent metric-list
```

The output of this command provides the item key of each metric, its latest value, and the time when this value was received. For example:

```
system.memory[active]          7921004544      1564570818
system.memory[swap_cache]      868352      1564570818
pgsql.connections[idle]        6.0        1564570818
pgsql.archive_command[failed_trying_to_archive] 0        1564570818
```

To view the current value for a specific metric, you can use the `agent metric-get` command:

```
mamonsu agent metric-get metric_name
```

where `metric_name` is the item key of the metric to monitor, as returned by the `metric-list` command. For example, `pgsql.connections[idle]`.

You can view graphs for the collected metrics in the Zabbix web interface under the **Graphs** menu. For details on working with Zabbix, see its official documentation at <https://www.zabbix.com/documentation/current/manual>.

If you have chosen to save all the collected metrics data into a file, as explained in [the section called “Logging Parameters”](#), you can later upload these metrics onto a Zabbix server for visualization using the `upload` command.

Adding Custom Plugins

You can extend mamonsu with your own custom plugins, as follows:

1. Save all custom plugins in a single directory, such as `/etc/mamonsu/plugins`.
2. Make sure this directory is specified in your configuration file under the `[plugins]` section:

```
[plugins]
directory = /etc/mamonsu/plugins
```

3. Generate a new Zabbix template to include custom plugins:

```
mamonsu export template template.xml --add-plugins=/etc/mamonsu/plugins
```

4. Upload the generated `template.xml` to the Zabbix server as explained in [the section called “Installation and Setup”](#).

Tuning Postgres Pro and System Configuration

Based on the collected metrics data, mamonsu can tune your Postgres Pro and system configuration for optimal performance.

You can get detailed information about the hardware, operating system, memory usage and other parameters of the monitored system, as well as Postgres Pro configuration, as follows:

```
mamonsu report
```

To view the suggested optimizations without applying them, run the `tune` command with the `--dry-run` option:

```
mamonsu tune --dry-run
```

To apply all the suggested changes, run the `tune` command without any parameters:

```
mamonsu tune
```

You can exclude some settings from the report or disable some of the optimizations by passing optional parameters. See [the section called “Command-Line Reference”](#) for the full list of parameters available for `report` and `tune` commands.

Managing Zabbix Server Settings from the Command Line

`mamonsu` enables you to work with the Zabbix server from the command line. You can upload template files to Zabbix, create and delete Zabbix hosts and host groups, link templates with hosts and check the latest metric values.

To set up your Zabbix host from scratch, you can follow these steps:

1. Optionally, specify your Zabbix account settings in the following environment variables on your monitoring system:
 - Set the `ZABBIX_USER` and `ZABBIX_PASSWD` variables to the login and password of your Zabbix account, respectively.
 - Set the `ZABBIX_URL` to `http://zabbix/`

If you skip this step, you will have to add the following options to all `mamonsu zabbix` commands that you run:

```
--url=http://zabbix/ --user=zabbix_login --password=zabbix_password
```

2. Generate a new template file and upload it to the Zabbix server:

```
mamonsu export template template.xml
mamonsu zabbix template export template.xml
```

3. Create a new host group:

```
mamonsu zabbix hostgroup create hostgroup_name
```

4. Check the IDs for this host group and the uploaded template, which are assigned automatically by the Zabbix server:

```
mamonsu zabbix hostgroup id hostgroup_name
mamonsu zabbix template id template_name
```

5. Create a host associated with this group and link it with the uploaded template using a single command:

```
mamonsu zabbix host create host_name hostgroup_id template_id mamonsu_address
```

where *host_name* is the name of the host, *hostgroup_id* and *template_id* are the unique IDs returned in the previous step, and *mamonsu_address* is the IP address of the system on which `mamonsu` runs.

Once your Zabbix host is configured, complete the setup of your monitoring system as explained in [the section called “Installation and Setup”](#).

Exporting Metrics for Native Zabbix Agent

Using `mamonsu`, you can convert system and Postgres Pro metrics definitions to the format supported by the native [Zabbix agent](#).

This feature currently has the following limitations:

- You cannot export metrics if you run `mamonsu` on Windows systems.
- Metrics definitions for `pg_wait_sampling` and CFS features available in Postgres Pro Enterprise are not converted.

Important

To work with Zabbix proxy, you must export settings to the format supported by the native Zabbix agent.

To collect metrics provided by mamonsu using the native Zabbix agent, do the following:

1. Generate a configuration file that is compatible with the native Zabbix agent and place it under `/etc/zabbix/zabbix_agent.d/`. You can prepend the filename with the required path:

```
mamonsu export zabbix-parameters /etc/zabbix/zabbix_agent.d/zabbix_agent.conf
```

For all possible options of the `export zabbix-parameters` command, see [the section called “Command-Line Reference”](#).
2. Generate a template for the native Zabbix agent:

```
mamonsu export zabbix-template template.xml
```

For all possible options of the `export zabbix-template` command, see [the section called “Command-Line Reference”](#).
3. Upload the generated template to the Zabbix server, as explained in [the section called “Installation and Setup”](#).
4. If you are going to collect Postgres Pro metrics, change the following macros in the template after the upload:
 - For `{$PG_CONNINFO}`, provide connection parameters for the Postgres Pro server to be monitored.
 - For `{$PG_PATH}`, specify `psql` installation directory.

Compatibility Considerations

If you want to upgrade mamonsu to a version that is not compatible with the previous one, what you must do to continue using the application depends on whether you need to retain the metrics data collected.

- If you need to retain the collected data, do the following:
 1. Install the new version of mamonsu.
 2. Generate a new template for the Zabbix server.
 3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
 4. Upload the new template to the Zabbix server.
 5. Rename the host for which you want to retain the collected data and leave the old template linked to that host.
 6. Create a new host for the same system and link the new template to it.
 7. Restart mamonsu. It will collect data for the new host. The old host will no longer be used, but the data collected will be available.
- If you do not need to retain the collected data, do the following:
 1. Install the new version of mamonsu.
 2. Generate a new template for the Zabbix server.
 3. If you performed a bootstrap using the previous version of mamonsu, run the `bootstrap` command again.
 4. Upload the new template to the Zabbix server.

5. In the settings of the Zabbix host, link the new template to the host instead of the old one.
6. Restart mamonsu. It will start collecting data. All the data collected earlier will be lost.

pgbouncer

pgbouncer — a Postgres Pro connection pooler

Synopsis

On Linux systems:

```
pgbouncer [ -d ] [ -R ] [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

On Windows:

```
pgbouncer [ -v ] [ -u user ] pgbouncer.ini
```

```
pgbouncer -V | -h
```

To use pgbouncer as a Windows service:

```
pgbouncer.exe --regservice pgbouncer.ini
```

```
pgbouncer.exe --unregservice pgbouncer.ini
```

Description

pgbouncer is a Postgres Pro connection pooler. Any target application can be connected to pgbouncer as if it were a Postgres Pro server, and pgbouncer will create a connection to the actual server, or it will reuse one of its existing connections.

The aim of pgbouncer is to lower the performance impact of opening new connections to Postgres Pro.

In order not to compromise transaction semantics for connection pooling, pgbouncer supports several types of pooling when rotating connections:

Session pooling

Most polite method. When a client connects, a server connection will be assigned to it for the whole duration the client stays connected. When the client disconnects, the server connection will be put back into the pool. This is the default method.

Transaction pooling

A server connection is assigned to a client only during a transaction. When pgbouncer notices that transaction is over, the server connection will be put back into the pool.

Statement pooling

Most aggressive method. The server connection will be put back into the pool immediately after a query completes. Multi-statement transactions are disallowed in this mode as they would break.

The administration interface of pgbouncer consists of some new `SHOW` commands available when connected to a special “virtual” database `pgbouncer`.

Quick Start

Basic setup and usage is as follows.

1. Create a `pgbouncer.ini` file. Details in the `pgbouncer(5)` man page. Simple example:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser
```

```
[pgbouncer]
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = userlist.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
```

2. Create a `userlist.txt` file that contains the users allowed in:

```
"someuser" "same_password_as_in_server"
```

3. Launch `pgbouncer`:

```
$ pgbouncer -d pgbouncer.ini
```

Note

The above command does not work on Windows systems. Instead, `pgbouncer` must be launched as a service that first needs to be registered, as follows:

```
pgbouncer --regservice
```

4. Have your application (or the `psql` client) connect to `pgbouncer` instead of directly to the PostgreSQL server:

```
$ psql -p 6432 -U someuser template1
```

5. Manage `pgbouncer` by connecting to the special administration database `pgbouncer` and issuing `SHOW HELP`; to begin:

```
$ psql -p 6432 -U someuser pgbouncer
pgbouncer=# SHOW HELP;
NOTICE:  Console usage
DETAIL:
SHOW [HELP|CONFIG|DATABASES|FDS|POOLS|CLIENTS|SERVERS|SOCKETS|LISTS|VERSION|...]
SET key = arg
RELOAD
PAUSE
SUSPEND
RESUME
SHUTDOWN
[...]
```

6. If you made changes to the `pgbouncer.ini` file, you can reload it with:

```
pgbouncer=# RELOAD;
```

Options

`-d, --daemon`

Run in the background. Without it, the process will run in the foreground. In daemon mode, setting `pidfile` as well as `logfile` or `syslog` is required. No log messages will be written to `stderr` after going into the background.

Note

Does not work on Windows, `pgbouncer` needs to run as service there.

`-R, --reboot`

Note

This option is deprecated. Instead of this option use a rolling restart with multiple pgbouncer processes listening on the same port using `so_reuseport` instead.

Do an online restart. That means connecting to the running process, loading the open sockets from it, and then using them. If there is no active process, boot normally.

Note

Works only if OS supports Unix sockets and the `unix_socket_dir` is not disabled in configuration. Does not work on Windows. Does not work with TLS connections, they are dropped.

`-u user, --user user`

Switch to the given user on startup.

`-v, --verbose`

Increase verbosity. Can be used multiple times.

`-q, --quiet`

Be quiet: do not log to stderr. This does not affect logging verbosity, only that stderr is not to be used. For use in `init.d` scripts.

`-V, --version`

Show version.

`-h, --help`

Show short help.

`--regservice`

Win32: Register to run as Windows service. The `service_name` configuration parameter value is used as the name to register under.

`--unregservice`

Win32: Unregister Windows service.

Admin Console

The console is available by connecting as normal to the database pgbouncer:

```
$ psql -p 6432 pgbouncer
```

Only users listed in the configuration parameters `admin_users` or `stats_users` are allowed to log in to the console. (Except when `auth_mode=any`, then any user is allowed in as a `stats_user`.)

Additionally, the user name `pgbouncer` is allowed to log in without password, if the login comes via the Unix socket and the client has same Unix user uid as the running process.

The admin console currently only supports the simple query protocol. Some drivers use the extended query protocol for all commands; these drivers will not work for this.

Show Commands

The `SHOW` commands output information. Each command is described below.

SHOW STATS

Shows statistics. In this and related commands, the total figures are since process start, the averages are updated every `stats_period`.

database

Statistics are presented per database.

total_xact_count

Total number of SQL transactions pooled by pgbouncer.

total_query_count

Total number of SQL queries pooled by pgbouncer.

total_received

Total volume in bytes of network traffic received by pgbouncer.

total_sent

Total volume in bytes of network traffic sent by pgbouncer.

total_xact_time

Total number of microseconds spent by pgbouncer when connected to Postgres Pro in a transaction, either idle in transaction or executing queries.

total_query_time

Total number of microseconds spent by pgbouncer when actively connected to Postgres Pro, executing queries.

total_wait_time

Time spent by clients waiting for a server, in microseconds. Updated when a client connection is assigned a backend connection.

avg_xact_count

Average transactions per second in last stat period.

avg_query_count

Average queries per second in last stat period.

avg_recv

Average received (from clients) bytes per second.

avg_sent

Average sent (to clients) bytes per second.

avg_xact_time

Average transaction duration, in microseconds.

avg_query_time

Average query duration, in microseconds.

avg_wait_time

Average time spent by clients waiting for a server that were assigned a backend connection within the current `stats_period`, in microseconds (average per second within that period).

SHOW STATS_TOTALS

Subset of `SHOW STATS` showing the total values (`total_`).

SHOW STATS_AVERAGES

Subset of `SHOW STATS` showing the average values (`avg_`).

SHOW TOTALS

Like `SHOW STATS` but aggregated across all databases.

SHOW SERVERS

`type`

S, for server.

`user`

User name pgbouncer uses to connect to server.

`database`

Database name.

`state`

State of the pgbouncer server connection, one of `active`, `idle`, `used`, `tested`, `new`, `active_cancel`, or `being_canceled`.

`addr`

IP address of Postgres Pro server.

`port`

Port of Postgres Pro server.

`local_addr`

Connection start address on local machine.

`local_port`

Connection start port on local machine.

`connect_time`

When the connection was made.

`request_time`

When last request was issued.

`wait`

Not used for server connections.

`wait_us`

Not used for server connections.

`close_needed`

1 if the connection will be closed as soon as possible, because a configuration file reload or DNS update changed the connection information or `RECONNECT` was issued.

`ptr`

Address of internal object for this connection. Used as unique ID.

link

Address of client connection the server is paired with.

remote_pid

PID of backend server process. In case connection is made over Unix socket and OS supports getting process ID info, its OS PID. Otherwise it's extracted from cancel packet the server sent, which should be the PID in case the server is Postgres Pro, but it's a random number in case the server is another pgbouncer.

tls

A string with TLS connection information, or empty if not using TLS.

application_name

A string containing the `application_name` set on the linked client connection, or empty if this is not set, or if there is no linked connection.

SHOW CLIENTS

type

C, for client.

user

Client connected user.

database

Database name.

state

State of the client connection, one of `active`, `waiting`, `active_cancel_req`, or `waiting_cancel_req`.

addr

IP address of the client.

port

Source port of the client.

local_addr

Connection end address on local machine.

local_port

Connection end port on local machine.

connect_time

Timestamp of connect time.

request_time

Timestamp of latest client request.

wait

Current waiting time in seconds.

wait_us

Microsecond part of the current waiting time.

close_needed

Not used for clients.

ptr

Address of internal object for this connection. Used as unique ID.

link

Address of server connection the client is paired with.

remote_pid

Process ID, in case client connects over Unix socket and OS supports getting it.

tls

A string with TLS connection information, or empty if not using TLS.

application_name

A string containing the `application_name` set by the client for this connection, or empty if this is not set.

SHOW POOLS

A new pool entry is made for each couple of (database, user).

database

Database name.

user

User name.

cl_active

Client connections that are either linked to server connections or are idle with no queries waiting to be processed.

cl_waiting

Client connections that have sent queries but have not yet got a server connection.

cl_active_cancel_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl_waiting_cancel_req

Client connections that have not forwarded query cancellations to the server yet.

sv_active

Server connections that are linked to a client.

sv_active_cancel

Server connections that are currently forwarding a cancel request.

sv_being_canceled

Servers that normally could become idle but are waiting to do so until all in-flight cancel requests have completed that were sent to cancel a query on this server.

sv_idle

Server connections that are unused and immediately usable for client queries.

sv_used

Server connections that have been idle for more than `server_check_delay`, so they need `server_check_query` to run on them before they can be used again.

sv_tested

Server connections that are currently running either `server_reset_query` or `server_check_query`.

sv_login

Server connections currently in the process of logging in.

maxwait

How long the first (oldest) client in the queue has waited, in seconds. If this starts increasing, then the current pool of servers does not handle requests quickly enough. The reason may be either an overloaded server or just too small of a `pool_size` setting.

maxwait_us

Microsecond part of the maximum waiting time.

pool_mode

The pooling mode in use.

SHOW PEER_POOLS

A new `peer_pool` entry is made for each configured peer.

database

ID of the configured peer entry.

cl_active_cancel_req

Client connections that have forwarded query cancellations to the server and are waiting for the server response.

cl_waiting_cancel_req

Client connections that have not forwarded query cancellations to the server yet.

sv_active_cancel

Server connections that are currently forwarding a cancel request.

sv_login

Server connections currently in the process of logging in.

SHOW LISTS

Show following internal information, in columns (not rows):

databases

Count of databases.

users

Count of users.

pools

Count of pools.

free_clients

Count of free clients.

used_clients

Count of used clients.

login_clients

Count of clients in login state.

free_servers

Count of free servers.

used_servers

Count of used servers.

dns_names

Count of DNS names in the cache.

dns_zones

Count of DNS zones in the cache.

dns_queries

Count of in-flight DNS queries.

dns_pending

Not used.

SHOW USERS

name

The user name.

pool_mode

The user's override `pool_mode`, or `NULL` if the default will be used instead.

SHOW DATABASES

name

Name of configured database entry.

host

Host pgbouncer connects to.

port

Port pgbouncer connects to.

database

Actual database name pgbouncer connects to.

`force_user`

When the user is part of the connection string, the connection between pgbouncer and Postgres Pro is forced to the given user, whatever the client user.

`pool_size`

Maximum number of server connections.

`min_pool_size`

Minimum number of server connections.

`reserve_pool`

Maximum number of additional connections for this database.

`pool_mode`

The database's override `pool_mode`, or `NULL` if the default will be used instead.

`max_connections`

Maximum number of allowed connections for this database, as set by `max_db_connections`, either globally or per database.

`current_connections`

Current number of connections for this database.

`paused`

1 if this database is currently paused, else 0.

`disabled`

1 if this database is currently disabled, else 0.

SHOW PEERS

`peer_id`

ID of the configured peer entry.

`host`

Host pgbouncer connects to.

`port`

Port pgbouncer connects to.

`pool_size`

Maximum number of server connections that can be made to this peer.

SHOW FDS

Internal command — shows list of file descriptors (FDs) in use with internal state attached to them.

When the connected user has the user name `pgbouncer`, connects through the Unix socket and has the same UID as the running process, the actual FDs are passed over the connection. This mechanism is used to do an online restart.

Note

This does not work on Windows.

This command also blocks the internal event loop, so it should not be used while pgbouncer is in use.

`fd`

File descriptor numeric value.

`task`

One of `pooler`, `client` or `server`.

`user`

User of the connection using the FD.

`database`

Database of the connection using the FD.

`addr`

IP address of the connection using the FD, `unix` if a Unix socket is used.

`port`

Port used by the connection using the FD.

`cancel`

Cancel key for this connection.

`link`

File descriptor for corresponding server/client. `NULL` if idle.

SHOW SOCKETS, SHOW ACTIVE_SOCKETS

Shows low-level information about sockets or only active sockets. This includes the information shown under `SHOW CLIENTS` and `SHOW SERVERS` as well as other more low-level information.

SHOW CONFIG

Show the current configuration settings, one per row, with the following columns:

`key`

Configuration variable name.

`value`

Configuration value.

`default`

Configuration default value.

`changeable`

Either `yes` or `no`, shows if the variable can be changed while running. If `no`, the variable can be changed only at boot-time. Use `SET` to change a variable at run time.

SHOW MEM

Shows low-level information about the current sizes of various internal memory allocations. The information presented is subject to change.

SHOW DNS_HOSTS

Show host names in DNS cache.

hostname

Host name.

ttl

How many seconds until next lookup.

addrs

Comma separated list of addresses.

SHOW DNS_ZONES

Show DNS zones in cache.

zonename

Zone name.

serial

Current serial.

count

Host names belonging to this zone.

SHOW VERSION

Show the pgbouncer version string.

SHOW STATE

Show the pgbouncer state settings. Current states are active, paused and suspended.

Process Controlling Commands

PAUSE [db]

pgbouncer tries to disconnect from all servers. Disconnecting each server connection waits for that server connection to be released according to the server pool's pooling mode (in transaction pooling mode, the transaction must complete, in statement mode, the statement must complete, and in session pooling mode the client must disconnect). The command will not return before all server connections have been disconnected. To be used at the time of database restart.

If database name is given, only that database will be paused.

New client connections to a paused database will wait until `RESUME` is called.

DISABLE db

Reject all new client connections on the given database.

ENABLE db

Allow new client connections after a previous `DISABLE` command.

RECONNECT db

Close each open server connection for the given database, or all databases, after it is released (according to the pooling mode), even if its lifetime is not up yet. New server connections can be made immediately and will connect as necessary according to the pool size settings.

This command is useful when the server connection setup has changed, for example to perform a gradual switchover to a new server. It is not necessary to run this command when the connection string in `pgbouncer.ini` has been changed and reloaded (see `RELOAD`) or when DNS resolution has changed,

because then the equivalent of this command will be run automatically. This command is only necessary if something downstream of pgbouncer routes the connections.

After this command is run, there could be an extended period where some server connections go to an old destination and some server connections go to a new destination. This is likely only sensible when switching read-only traffic between read-only replicas, or when switching between nodes of a multimas-ter replication setup. If all connections need to be switched at the same time, `PAUSE` is recommended instead. To close server connections without waiting (for example, in emergency failover rather than gradual switchover scenarios), also consider `KILL`.

KILL *db*

Immediately drop all client and server connections on given database.

New client connections to a killed database will wait until `RESUME` is called.

SUSPEND

All socket buffers are flushed and pgbouncer stops listening for data on them. The command will not return before all buffers are empty. To be used at the time of pgbouncer online reboot.

New client connections to a suspended database will wait until `RESUME` is called.

RESUME [*db*]

Resume work from previous `KILL`, `PAUSE`, or `SUSPEND` command.

SHUTDOWN

The pgbouncer process will exit.

RELOAD

The pgbouncer process will reload its configuration files and update changeable settings. This includes the main configuration file as well as the files specified by the settings `auth_file` and `auth_hba_file`.

pgbouncer notices when a configuration file reload changes the connection parameters of a database definition. An existing server connection to the old destination will be closed when the server connection is next released (according to the pooling mode), and new server connections will immediately use the updated connection parameters.

WAIT_CLOSE [*db*]

Wait until all server connections, either of the specified database or of all databases, have cleared the `close_needed` state (see [the section called “SHOW SERVERS”](#)). This can be called after a `RECONNECT` or `RELOAD` to wait until the respective configuration change has been fully activated, for example in switchover scripts.

Other Commands

SET *key* = *arg*

Changes a configuration setting (see also [the section called “SHOW CONFIG”](#)). For example:

```
SET log_connections = 1;
SET server_check_query = 'select 2';
```

(Note that this command is run on the pgbouncer admin console and sets pgbouncer settings. A `SET` command run on another database will be passed to the Postgres Pro backend like any other SQL command.)

Signals

`SIGHUP`

Reload config. Same as issuing the command `RELOAD` on the console.

SIGINT

Safe shutdown. Same as issuing `PAUSE` and `SHUTDOWN` on the console.

SIGTERM

Immediate shutdown. Same as issuing `SHUTDOWN` on the console.

SIGUSR1

Same as issuing `PAUSE` on the console.

SIGUSR2

Same as issuing `RESUME` on the console.

Libevent Settings

From the libevent documentation:

It is possible to disable support for `epoll`, `kqueue`, `devpoll`, `poll`, or `select` by setting the environment variable `EVENT_NOEPOLL`, `EVENT_NOKQUEUE`, `EVENT_NODEVPOLL`, `EVENT_NOPOLL` or `EVENT_NOSELECT`, respectively.

By setting the environment variable `EVENT_SHOW_METHOD`, libevent displays the kernel notification method that it uses.

pgbouncer.ini Configuration File

The configuration file is in the `.ini` format. Section names are between `[` and `]`. Lines starting with `;` or `#` are taken as comments and ignored. The characters `;` and `#` are not recognized as special when they appear later in the line.

Generic Settings

`logfile`

Specifies the log file. For daemonization (`-d`), either this or `syslog` has to be set. The log file is kept open, so after rotation, `kill -HUP` or on console `RELOAD;` should be done. On Windows, the service must be stopped and started.

Note that setting `logfile` does not by itself turn off logging to `stderr`. Use the command-line option `-q` or `-d` for that.

Default: not set

`pidfile`

Specifies the PID file. Without `pidfile` set, daemonization (`-d`) is not allowed.

Default: not set

`listen_addr`

Specifies a list (comma-separated) of addresses where to listen for TCP connections. You may also use `*` meaning "listen on all addresses". When not set, only Unix socket connections are accepted.

Addresses can be specified numerically (IPv4/IPv6) or by name.

Default: not set

`listen_port`

Which port to listen on. Applies to both TCP and Unix sockets.

Default: 6432

`unix_socket_dir`

Specifies the location for Unix sockets. Applies to both the listening socket and server connections. If set to an empty string, Unix sockets are disabled. A value that starts with @ specifies that a Unix socket in the abstract namespace should be created (currently supported on Linux and Windows).

For online reboot (-R) to work, a Unix socket needs to be configured, and it needs to be in the file-system namespace.

Default: /tmp (empty on Windows)

`unix_socket_mode`

File system mode for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: 0777

`unix_socket_group`

Group name to use for Unix socket. Ignored for sockets in the abstract namespace. Not supported on Windows.

Default: not set

`user`

If set, specifies the Unix user to change to after startup. Works only if pgbouncer is started as root or if it's already running as the given user.

Not supported on Windows.

Default: not set

`pool_mode`

Specifies when a server connection can be reused by other clients.

`session`

Server is released back to pool after client disconnects. Default.

`transaction`

Server is released back to pool after transaction finishes.

`statement`

Server is released back to pool after query finishes. Transactions spanning multiple statements are disallowed in this mode.

`max_client_conn`

Maximum number of client connections allowed.

When this setting is increased, then the file descriptor limits in the operating system might also have to be increased. Note that the number of file descriptors potentially used is more than `max_client_conn`. If each user connects under its own username to the server, the theoretical maximum used is:

`max_client_conn + (max pool_size * total databases * total users)`

If a database user is specified in the connection string (all users connect under the same user name), the theoretical maximum is:

`max_client_conn + (max pool_size * total databases)`

The theoretical maximum should never be reached, unless somebody deliberately crafts a special load for it. Still, it means you should set the number of file descriptors to a safely high number.

Search for `ulimit` in your favorite shell man page. Note: `ulimit` does not apply in a Windows environment.

Default: 100

`default_pool_size`

How many server connections to allow per user/database pair. Can be overridden in the per-database configuration.

Default: 20

`min_pool_size`

Add more server connections to pool if below this number. Improves the behavior when the normal load suddenly comes back after a period of total inactivity. The value is effectively capped at the pool size.

Default: 0 (disabled)

`reserve_pool_size`

How many additional connections to allow to a pool (see [reserve_pool_timeout](#)). The 0 value disables this parameter.

Default: 0 (disabled)

`reserve_pool_timeout`

If a client has not been serviced in this time, `pgbouncer` enables use of additional connections from the reserve pool. The 0 value disables this parameter. [seconds]

Default: 5.0

`max_db_connections`

Do not allow more than this many server connections per database (regardless of user). This considers the `pgbouncer` database that the client has connected to, not the Postgres Pro database of the outgoing connection. This can also be set per database in the `[databases]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

`max_user_connections`

Do not allow more than this many server connections per user (regardless of database). This considers the `pgbouncer` user that is associated with a pool, which is either the user specified for the server connection or in absence of that the user the client has connected as. This can also be set per user in the `[users]` section.

Note that when you hit the limit, closing a client connection to one pool will not immediately allow a server connection to be established for another pool, because the server connection for the first pool is still open. Once the server connection closes (due to idle timeout), a new server connection will immediately be opened for the waiting pool.

Default: 0 (unlimited)

server_round_robin

By default, pgbouncer reuses server connections in LIFO (last-in, first-out) manner, so that few connections get the most load. This gives best performance if you have a single server serving a database. But if there is a round-robin system behind a database address (TCP, DNS, or host list), then it is better if pgbouncer also uses connections in that manner, thus achieving uniform load.

Default: 0

track_extra_parameters

By default, pgbouncer tracks `client_encoding`, `datestyle`, `timezone`, `standard_conforming_strings` and `application_name` parameters per client. To allow other parameters to be tracked, they can be specified here, so that pgbouncer knows that they should be maintained in the client variable cache and restored in the server whenever the client becomes active.

If you need to specify multiple values, use a comma-separated list (e.g. `default_transaction_read-only, IntervalStyle`)

Note

Most parameters cannot be tracked this way. The only parameters that can be tracked are ones that Postgres Pro reports to the client. Postgres Pro has [an official list of parameters that it reports to the client](#). Postgres Pro extensions can change this list though, they can add parameters themselves that they also report, and they can start reporting already existing parameters that Postgres Pro does not report. Notably Citus 12.0+ causes PostgreSQL to also report `search_path`.

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `track_extra_parameters`. However, it's not possible to include `options` itself in `track_extra_parameters`, only the parameters contained in `options`.

Default: `IntervalStyle`

ignore_startup_parameters

By default, pgbouncer allows only parameters it can keep track of in startup packets: `client_encoding`, `datestyle`, `timezone` and `standard_conforming_strings`.

All other parameters will raise an error. To allow other parameters, they can be specified here, so that pgbouncer knows that they are handled by the admin and it can ignore them.

If you need to specify multiple values, use a comma-separated list (e.g. `options,extra_float_digits`).

The `postgres` protocol allows specifying parameter settings, both directly as a parameter in the startup packet, or inside the [options startup packet](#). Parameters specified using both of these methods are supported by `ignore_startup_parameters`. It's even possible to include `options` itself in `ignore_startup_parameters`, which results in any unknown parameters contained inside `options` to be ignored.

Default: empty

peer_id

The peer ID used to identify this pgbouncer process in a group of pgbouncer processes that are peered together. The `peer_id` value should be unique within a group of peered pgbouncer processes. When set to 0, pgbouncer peering is disabled. See also [\[peers\] Section](#) for more information. The maximum value that can be used for the `peer_id` is 16383.

Default: 0

`disable_pgexec`

Disable the Simple Query protocol (PQexec). Unlike the Extended Query protocol, Simple Query allows multiple queries in one packet, which allows some classes of SQL-injection attacks. Disabling it can improve security. Obviously, this means only clients that exclusively use the Extended Query protocol will stay working.

Default: 0

`application_name_add_host`

Add the client host address and port to the application name setting set on connection start. This helps in identifying the source of bad queries, etc. This logic applies only at the start of a connection. If `application_name` is later changed with `SET`, `pgbouncer` does not change it again.

Default: 0

`conffile`

Show location of current configuration file. Changing it will make `pgbouncer` use another configuration file for next `RELOAD` / `SIGHUP`.

Default: file from command line

`service_name`

Used on win32 service registration.

Default: `pgbouncer`

`job_name`

Alias for `service_name`.

`stats_period`

Sets how often the averages shown in various `SHOW` commands are updated and how often aggregated statistics are written to the log (but see `log_stats`). [seconds]

Default: 60

Authentication Settings

`pgbouncer` handles its own client authentication and has its own database of users. These settings control this.

`auth_type`

How to authenticate users.

`cert`

The client must connect over TLS connection with a valid client certificate. The user name is then taken from the `CommonName` field from the certificate.

`md5`

Use MD5-based password check. This is the default authentication method. `auth_file` may contain both MD5-encrypted and plain-text passwords. If `md5` is configured and a user has a SCRAM secret, then SCRAM authentication is used automatically instead.

`scram-sha-256`

Use password check with SCRAM-SHA-256. `auth_file` has to contain SCRAM secrets or plain-text passwords. Note that SCRAM secrets can only be used for verifying the password of a client

but not for logging into a server. To be able to use SCRAM on server connections, use plain-text passwords.

plain

The clear-text password is sent over the wire. Deprecated.

trust

No authentication is done. The user name must still exist in `auth_file`.

any

Like the `trust` method, but the user name given is ignored. Requires that all databases are configured to log in as a specific user. Additionally, the console database allows any user to log in as admin.

hba

The actual authentication type is loaded from `auth_hba_file`. This allows different authentication methods for different access paths, for example: connections over Unix socket use `peer` authentication method, connections over TCP must use TLS.

pam

Pluggable Authentication Modules (PAM) method is used to authenticate users, `auth_file` is ignored. This method is not compatible with databases using the `auth_user` option. The service name reported to PAM is `pgbouncer`. `pam` is not supported in the HBA configuration file.

auth_hba_file

HBA configuration file to use when `auth_type` is `hba`.

Default: not set

auth_file

The name of the file to load user names and passwords from. See [the section called “Authentication File Format”](#) for details.

Most authentication types (see `auth_type`) require that either `auth_file` or `auth_user` be set; otherwise there would be no users defined.

Default: not set

auth_user

If `auth_user` is set, then any user not specified in `auth_file` will be queried through the `auth_query` query from `pg_shadow` in the database, using `auth_user`. The password of `auth_user` will be taken from `auth_file`. (If `auth_user` does not require a password, then it does not need to be defined in `auth_file`.)

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Default: not set

auth_query

Query to load user's password from database.

Direct access to `pg_shadow` requires admin rights. It's preferable to use a non-superuser that calls a `SECURITY DEFINER` function instead.

Note that the query is run inside the target database. So if a function is used, it needs to be installed into each database.

Default: `SELECT username, passwd FROM pg_shadow WHERE username=$1`

`auth_dbname`

Database name in the [\[databases\] section](#) to be used for authentication purposes. This option can be either global or overridden in the connection string if this parameter is specified.

Log Settings

`syslog`

Toggles syslog on/off. On Windows, the event log is used instead.

Default: 0

`syslog_ident`

Under what name to send logs to syslog.

Default: `pgbouncer` (program name)

`syslog_facility`

Under what facility to send logs to syslog. Possibilities: `auth`, `authpriv`, `daemon`, `user`, `local0-7`.

Default: `daemon`

`log_connections`

Log successful logins.

Default: 1

`log_disconnections`

Log disconnections with reasons.

Default: 1

`log_pooler_errors`

Log error messages the pooler sends to clients.

Default: 1

`log_stats`

Write aggregated statistics into the log, every [stats_period](#). This can be disabled if external monitoring tools are used to grab the same data from `SHOW` commands.

Default: 1

`verbose`

Increase verbosity. Mirrors the `-v` switch on the command line. For example, using `-v -v` on the command line is the same as `verbose=2`.

Default: 0

Console Access Control

`admin_users`

Comma-separated list of database users that are allowed to connect and run all commands on the console. Ignored when [auth_type](#) is `any`, in which case any user name is allowed in as admin.

Default: empty

`stats_users`

Comma-separated list of database users that are allowed to connect and run read-only queries on the console. That means all `SHOW` commands except `SHOW FDS`.

Default: empty

Connection Sanity Checks, Timeouts`server_reset_query`

Query sent to server on connection release, before making it available to other clients. At that moment no transaction is in progress, so the value should not include `ABORT` or `ROLLBACK`.

The query is supposed to clean any changes made to the database session so that the next client gets the connection in a well-defined state. The default is `DISCARD ALL`, which cleans everything, but that leaves the next client no pre-cached state. It can be made lighter, e.g. `DEALLOCATE ALL` to just drop prepared statements, if the application does not break when some state is kept around.

When transaction pooling is used, the `server_reset_query` is not used, because in that mode, clients must not use any session-based features, since each transaction ends up in a different connection and thus gets a different session state.

Default: `DISCARD ALL`

`server_reset_query_always`

Whether `server_reset_query` should be run in all pooling modes. When this setting is off (default), the `server_reset_query` will be run only in pools that are in sessions-pooling mode. Connections in transaction-pooling mode should not have any need for a reset query.

This setting is for working around broken setups that run applications that use session features over a transaction-pooled pgbouncer. It changes non-deterministic breakage to deterministic breakage: clients always lose their state after each transaction.

Default: 0

`server_check_delay`

How long to keep released connections available for immediate re-use, without running `server_check_query` on it. If 0 then the query is always run.

Default: 30.0

`server_check_query`

Simple do-nothing query to check if the server connection is alive.

If an empty string, then sanity checking is disabled.

Default: `select 1`

`server_fast_close`

Disconnect a server in session pooling mode immediately or after the end of the current transaction if it is in `close_needed` mode (set by `RECONNECT`, `RELOAD` that changes connection settings, or DNS change), rather than waiting for the session end. In statement or transaction pooling mode, this has no effect since that is the default behavior there.

If because of this setting a server connection is closed before the end of the client session, the client connection is also closed. This ensures that the client notices that the session has been interrupted.

This setting makes connection configuration changes take effect sooner if session pooling and long-running sessions are used. The downside is that client sessions are liable to be interrupted by a

configuration change, so client applications will need logic to reconnect and reestablish session state. But note that no transactions will be lost, because running transactions are not interrupted, only idle sessions.

Default: 0

`server_lifetime`

The pooler will close an unused (not currently linked to any client connection) server connection that has been connected longer than this. Setting it to 0 means the connection is to be used only once, then closed. [seconds]

Default: 3600.0

`server_idle_timeout`

If a server connection has been idle more than this many seconds it will be closed. If 0 then timeout is disabled. [seconds]

Default: 600.0

`server_connect_timeout`

If connection and login don't finish in this amount of time, the connection will be closed. [seconds]

Default: 15.0

`server_login_retry`

If login to the server failed, because of failure to connect or from authentication, the pooler waits this much before retrying to connect. During the waiting interval, new clients trying to connect to the failing server will get an error immediately without another connection attempt. [seconds]

The purpose of this behavior is that clients don't unnecessarily queue up waiting for a server connection to become available if the server is not working. However, it also means that if a server is momentarily failing, for example during a restart or if the configuration was erroneous, then it will take at least this long until the pooler will consider connecting to it again. Planned events such as restarts should normally be managed using the `PAUSE` command to avoid this.

Default: 15.0

`client_login_timeout`

If a client connects but does not manage to log in in this amount of time, it will be disconnected. Mainly needed to avoid dead connections stalling `SUSPEND` and thus online restart. [seconds]

Default: 60.0

`autodb_idle_timeout`

If the automatically created (via `"*`") database pools have been unused this many seconds, they are freed. The negative aspect of that is that their statistics are also forgotten. [seconds]

Default: 3600.0

`dns_max_ttl`

How long DNS lookups can be cached. The actual DNS TTL is ignored. [seconds]

Default: 15.0

`dns_nxdomain_ttl`

How long DNS errors and `NXDOMAIN` DNS lookups can be cached. [seconds]

Default: 15.0

`dns_zone_check_period`

Period to check if a zone serial has changed.

pgbouncer can collect DNS zones from host names (everything after first dot) and then periodically check if the zone serial changes. If it notices changes, all host names under that zone are looked up again. If any host IP changes, its connections are invalidated.

Default: 0.0 (disabled)

`resolv_conf`

The location of a custom `resolv.conf` file. This is to allow specifying custom DNS servers and perhaps other name resolution options, independent of the global operating system configuration.

The parsing of the file is done by the DNS backend library, not pgbouncer, so see the library's documentation for details on allowed syntax and directives.

Default: empty (use operating system defaults)

TLS Settings

`client_tls_sslmode`

TLS mode to use for connections from clients. TLS connections are disabled by default. When enabled, `client_tls_key_file` and `client_tls_cert_file` must be also configured to set up the key and certificate pgbouncer uses to accept client connections.

`disable`

Plain TCP. If client requests TLS, it's ignored. Default.

`allow`

If client requests TLS, it is used. If not, plain TCP is used. If the client presents a client certificate, it is not validated.

`prefer`

Same as `allow`.

`require`

The client must use TLS. If not, the client connection is rejected. If the client presents a client certificate, it is not validated.

`verify-ca`

Client must use TLS with valid client certificate.

`verify-full`

Same as `verify-ca`.

`client_tls_key_file`

Private key for pgbouncer to accept client connections.

Default: not set

`client_tls_cert_file`

Certificate for private key. Clients can validate it.

Default: not set

`client_tls_ca_file`

Root certificate file to validate client certificates.

Default: not set

`client_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`client_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

`client_tls_ecdhcurve`

Elliptic Curve name to use for ECDH key exchanges.

Allowed values: `none` (DH is disabled), `auto` (256-bit ECDH), curve name.

Default: `auto`

`client_tls_dheparams`

DHE key exchange type.

Allowed values: `none` (DH is disabled), `auto` (2048-bit DH), `legacy` (1024-bit DH).

Default: `auto`

`server_tls_sslmode`

TLS mode to use for connections to Postgres Pro servers. The default mode is `prefer`.

`disable`

Plain TCP. TLS is not even requested from the server.

`prefer`

TLS connection is always requested first from Postgres Pro. If refused, the connection will be established over plain TCP. Server certificate is not validated. Default.

`require`

Connection must go over TLS. If server rejects it, plain TCP is not attempted. Server certificate is not validated.

`verify-ca`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name is not checked against certificate.

`verify-full`

Connection must go over TLS and server certificate must be valid according to `server_tls_ca_file`. Server host name must match certificate information.

`server_tls_ca_file`

Root certificate file to validate Postgres Pro server certificates.

Default: not set

`server_tls_key_file`

Private key for pgbouncer to authenticate against Postgres Pro server.

Default: not set

`server_tls_cert_file`

Certificate for private key. Postgres Pro server can validate it.

Default: not set

`server_tls_protocols`

Which TLS protocol versions are allowed. Allowed values: `tlsv1.0`, `tlsv1.1`, `tlsv1.2`, `tlsv1.3`. Shortcuts: `all` (`tlsv1.0,tlsv1.1,tlsv1.2,tlsv1.3`), `secure` (`tlsv1.2,tlsv1.3`), `legacy` (`all`).

Default: `secure`

`server_tls_ciphers`

Allowed TLS ciphers, in OpenSSL syntax. Shortcuts: `default/secure`, `compat/legacy`, `insecure/all`, `normal`, `fast`.

Only connections using TLS version 1.2 and lower are affected. There is currently no setting that controls the cipher choices used by TLS version 1.3 connections.

Default: `fast`

Dangerous Timeouts

Setting the following timeouts can cause unexpected errors.

`query_timeout`

Queries running longer than that are canceled. This should be used only with a slightly smaller server-side `statement_timeout`, to apply only for network problems. [seconds]

Default: 0.0 (disabled)

`query_wait_timeout`

Maximum time queries are allowed to spend waiting for execution. If the query is not assigned to a server during that time, the client is disconnected. The 0 value disables this parameter. If this is disabled, clients will be queued indefinitely. [seconds]

This setting is used to prevent unresponsive servers from grabbing up connections. It also helps when the server is down or rejects connections for any reason.

Default: 120.0

`cancel_wait_timeout`

Maximum time cancellation requests are allowed to spend waiting for execution. If the cancel request is not assigned to a server during that time, the client is disconnected. 0 disables. If this is disabled, cancel requests will be queued indefinitely. [seconds]

This setting is used to prevent a client locking up when a cancel cannot be forwarded due to the server being down.

Default: 10.0

`client_idle_timeout`

Client connections idling longer than this many seconds are closed. This should be larger than the client-side connection lifetime settings, and only used for network problems. [seconds]

Default: 0.0 (disabled)

`idle_transaction_timeout`

If a client has been in the “idle in transaction” state longer, it will be disconnected. [seconds]

Default: 0.0 (disabled)

`suspend_timeout`

How long to wait for buffer flush during `SUSPEND` or reboot (`-R`). A connection is dropped if the flush does not succeed. [seconds]

Default: 10

Low-Level Network Settings

`pkt_buf`

Internal buffer size for packets. Affects size of TCP packets sent and general memory usage. Actual libpq packets can be larger than this, so no need to set it large.

Default: 4096

`max_packet_size`

Maximum size for Postgres Pro packets that pgbouncer allows through. One packet is either one query or one result set row. The full result set can be larger.

Default: 2147483647

`listen_backlog`

The value of the `backlog` argument for `listen()`. Determines how many new unanswered connection attempts are kept in the queue. When the queue is full, further new connections are dropped.

Default: 128

`sbuf_loopcnt`

How many times to process data on one connection, before proceeding. Without this limit, one connection with a big result set can stall pgbouncer for a long time. One loop processes one `pkt_buf` amount of data. 0 means no limit.

Default: 5

`so_reuseport`

Specifies whether to set the socket option `SO_REUSEPORT` on TCP listening sockets. On some operating systems, this allows running multiple pgbouncer instances on the same host listening on the same port and having the kernel distribute the connections automatically. This option is a way to get pgbouncer to use more CPU cores. (pgbouncer is single-threaded and uses one CPU core per instance.)

This setting has the desired effect on Linux. On systems that don't support the socket option at all, turning this setting on will result in an error.

Each pgbouncer instance on the same host needs different settings for at least `unix_socket_dir` and `pidfile`, as well as `logfile` if that is used. Also note that if you make use of this option, you can no longer connect to a specific pgbouncer instance via TCP/IP, which might have implications for monitoring and metrics collection.

To make sure query cancellations keep working, you should set up pgbouncer peering between the different pgbouncer processes. For details see the [peer_id configuration option](#) and the [\[peers\] configuration section](#). There's also an example that uses peering and `so_reuseport` in the [Examples section](#).

Default: 0

`tcp_defer_accept`

Sets the `TCP_DEFER_ACCEPT` socket option; see `man 7 tcp` for details. (This is a Boolean option: 1 means enabled. The actual value set if enabled is currently hardcoded to 45 seconds.)

This is currently only supported on Linux.

Default: 1 on Linux, otherwise 0

`tcp_socket_buffer`

Default: not set

`tcp_keepalive`

Turns on basic keepalive with OS defaults.

On Linux, the system defaults are **`tcp_keepidle=7200`**, **`tcp_keepintvl=75`**, **`tcp_keepcnt=9`**. They are probably similar on other operating systems.

Default: 1

`tcp_keepcnt`

Default: not set

`tcp_keepidle`

Default: not set

`tcp_keepintvl`

Default: not set

`tcp_user_timeout`

Sets the `TCP_USER_TIMEOUT` socket option. This specifies the maximum amount of time in milliseconds that transmitted data may remain unacknowledged before the TCP connection is forcibly closed. If set to 0, then operating system's default is used.

This is currently only supported on Linux.

Default: 0

Section [databases]

The section `[databases]` defines the names of the databases that clients of pgbouncer can connect to and specifies where those connections will be routed. The section contains `key=value` lines like

```
dbname = connection string
```

where the key will be taken as a database name and the value as a connection string, consisting of `key=value` pairs of connection parameters, described below (similar to `libpq`, but the actual `libpq` is not used and the set of available features is different).

Example:

```
foodb = host=host1.example.com port=5432
```

```
bardb = host=localhost dbname=bazdb
```

The database name can contain characters `_0-9A-Za-z` without quoting. Names that contain other chars need to be quoted with standard SQL ident quoting: double quotes where `"` is taken as single quote.

The database name `pgbouncer` is reserved for the admin console and cannot be used as a key here.

* acts as fallback database: if the exact name does not exist, its value is taken as connection string for the requested database. For example, if there is the following entry (and no other overriding entries):

```
* = host=foo
```

In this case, a connection to `pgbouncer` specifying a database `bar` will effectively behave as if the following entry exists (taking advantage of the default for `dbname` being the client-side database name):

```
bar = host=foo dbname=bar
```

Such automatically created database entries are cleaned up if they stay idle longer than the time specified by the `autodb_idle_timeout` parameter.

`dbname`

Destination database name.

Default: same as client-side database name

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. When a host name's resolution changes, existing server connections are automatically closed when they are released (according to the pooling mode), and new server connections immediately use the new resolution. If DNS returns several results, they are used in a round-robin manner.

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

A comma-separated list of host names or addresses can be specified. In that case, connections are made in a round-robin manner. (If a host list contains host names that in turn resolve via DNS to multiple addresses, the round-robin systems operate independently. This is an implementation dependency that is subject to change.) Note that in a list, all hosts must be available at all times: there are no mechanisms to skip unreachable hosts or to select only available hosts from a list or similar. (This is different from what a host list in `libpq` means.) Also note that this only affects how the destinations of new connections are chosen. See also the setting `server_round_robin` for how clients are assigned to already established server connections.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/postgresql
host=192.168.0.1,192.168.0.2,192.168.0.3
```

Default: not set, meaning to use a Unix socket

`port`

Default: 5432

`user`

If `user=` is set, all connections to the destination database will be done with the specified user, meaning that there will be only one pool for this database.

Otherwise pgbouncer logs into the destination database with the client user name, meaning that there will be one pool per user.

password

If no password is specified here, the password from the `auth_file` or `auth_query` will be used.

auth_user

Override of the global `auth_user` setting, if specified.

pool_size

Set the maximum size of pools for this database. If not set, the `default_pool_size` is used.

min_pool_size

Set the minimum pool size for this database. If not set, the global `min_pool_size` is used.

reserve_pool

Set additional connections for this database. If not set, `reserve_pool_size` is used.

connect_query

Query to be executed after a connection is established, but before allowing the connection to be used by any clients. If the query raises errors, they are logged but ignored otherwise.

pool_mode

Set the pool mode specific to this database. If not set, the default `pool_mode` is used.

max_db_connections

Configure a database-wide maximum (i.e. all pools within the database will not have more than this many server connections).

client_encoding

Ask specific `client_encoding` from server.

datestyle

Ask specific `datestyle` from server.

timezone

Ask specific `timezone` from server.

Section [users]

This section contains `key=value` lines like

```
user1 = settings
```

where the key will be taken as a user name and the value as a list of configuration settings specific for this user.

Example:

```
user1 = pool_mode=session
```

Only a few settings are available here.

pool_mode

Set the pool mode to be used for all connections from this user. If not set, the database or default `pool_mode` is used.

`max_user_connections`

Configure a maximum for the user (i.e. all pools with the user will not have more than this many server connections).

Section [peers]

This section defines the peers that pgbouncer can forward cancellation requests to and where those cancellation requests will be routed.

pgbouncer processes can be peered together in a group by defining a `peer_id` value and a [peers] section in the configs of all the pgbouncer processes. These pgbouncer processes can then forward cancellation requests to the process that it originated from. This is needed to make cancellations work when multiple pgbouncer processes (possibly on different servers) are behind the same TCP load balancer. Cancellation requests are sent over different TCP connections than the query they are cancelling, so a TCP load balancer might send the cancellation request connection to a different process than the one that it was meant for. By peering them these cancellation requests eventually end up at the right process.

The section contains key=value lines like

```
peer_id = connection string
```

where the key will be taken as a `peer_id` and the value as a connection string, consisting of key=value pairs of connection parameters, described below (similar to libpq, but the actual libpq is not used and the set of available features is different).

Example:

```
1 = host=host1.example.com
2 = host=/tmp/pgbouncer-2 port=5555
```

Note

For peering to work, the `peer_id` of each pgbouncer process in the group must be unique within the peered group. And the [peers] section should contain entries for each of those peer IDs. An example can be found in the [Examples](#) section. It is allowed, but not necessary, for the [peers] section to contain the `peer_id` of the pgbouncer that the config is for. Such an entry will be ignored, but it is allowed to make config management easier. Because it allows using the exact same [peers] section for multiple configs.

`host`

Host name or IP address to connect to. Host names are resolved at connection time, the result is cached per `dns_max_ttl` parameter. If DNS returns several results, they are used in a round-robin manner. But in general it's not recommended to use a hostname that resolves to multiple IPs, because then the cancel request might still be forwarded to the wrong node and it would need to be forwarded again (which is only allowed up to three times).

If the value begins with `/`, then a Unix socket in the file-system namespace is used. If the value begins with `@`, then a Unix socket in the abstract namespace is used.

Examples:

```
host=localhost
host=127.0.0.1
host=2001:0db8:85a3:0000:0000:8a2e:0370:7334
host=/var/run/pgbouncer-1
```

`port`

Default: 6432

`pool_size`

If not set, the `default_pool_size` is used.

Include Directive

The pgbouncer configuration file can contain include directives, which specify another configuration file to read and process. This allows splitting the configuration file into physically separate parts. The include directives look like this:

```
%include filename
```

If the filename is not an absolute path, it is taken as relative to the current working directory.

Authentication File Format

This section describes the format of the file specified by the `auth_file` setting. It is a text file in the following format:

```
"username1" "password" ...
"username2" "md5abcdef012342345" ...
"username2" "SCRAM-SHA-256$iterations:salt$storedkey:serverkey"
```

There should be at least two fields, surrounded by double quotes. The first field is the user name and the second is either a plain-text, a MD5-hashed password, or a SCRAM secret. pgbouncer ignores the rest of the line. Double quotes in a field value can be escaped by writing two double quotes.

Postgres Pro MD5-hashed password format:

```
"md5" + md5(password + username)
```

```
So      user      admin      with      password      1234      will      have      MD5-hashed      password
md545f2603610af569b6155c45067268c6b.
```

Postgres Pro SCRAM secret format:

```
SCRAM-SHA-256$iterations:salt$storedkey:serverkey
```

The passwords or secrets stored in the authentication file serve two purposes. First, they are used to verify the passwords of incoming client connections, if a password-based authentication method is configured. Second, they are used as the passwords for outgoing connections to the backend server, if the backend server requires password-based authentication (unless the password is specified directly in the database's connection string). The latter works if the password is stored in plain text or MD5-hashed. SCRAM secrets can only be used for logging into a server if the client authentication also uses SCRAM, the pgbouncer database definition does not specify a user name, and the SCRAM secrets are identical in pgbouncer and the Postgres Pro server (same salt and iterations, not merely the same password). This is due to an inherent security property of SCRAM: the stored SCRAM secret cannot by itself be used for deriving login credentials.

The authentication file can be written by hand, but it's also useful to generate it from some other list of users and passwords. See `./etc/mkauth.py` for a sample script to generate the authentication file from the `pg_shadow` system table.

Alternatively, use `auth_query` instead of `auth_file` to avoid having to maintain a separate authentication file.

HBA File Format

The location of the HBA file is specified by the setting `auth_hba_file`. It is only used if `auth_type` is set to `hba`.

The file follows the format of the Postgres Pro `pg_hba.conf` file described in [Section 20.1](#).

- Supported record types: `local`, `host`, `hostssl`, `hostnossl`.

- **Database field:** Supports `all`, `sameuser`, `@file`, multiple names. Not supported: `replication`, `samerole`, `samegroup`.
- **User name field:** Supports `all`, `@file`, multiple names. Not supported: `+groupname`.
- **Address field:** Supports `IPv4`, `IPv6`. Not supported: DNS names, domain prefixes.
- **Auth-method field:** Only methods supported by pgbouncer's `auth_type` are supported, plus `peer` and `reject`, but except `any` and `pam`, which only work globally. User name map (`map=`) parameter is not supported.

Examples

Small example configuration:

```
[databases]
template1 = host=localhost dbname=template1 auth_user=someuser

[pgbouncer]
pool_mode = session
listen_port = 6432
listen_addr = localhost
auth_type = md5
auth_file = users.txt
logfile = pgbouncer.log
pidfile = pgbouncer.pid
admin_users = someuser
stats_users = stat_collector
```

Database examples:

```
[databases]

; foodb over Unix socket
foodb =

; redirect bardb to bazdb on localhost
bardb = host=localhost dbname=bazdb

; access to destination database will go with single user
forcedb = host=localhost port=300 user=baz password=foo client_encoding=UNICODE
datestyle=ISO
```

Example of a secure function for `auth_query`:

```
CREATE OR REPLACE FUNCTION pgbouncer.user_lookup(in i_username text, out uname text,
out phash text)
RETURNS record AS $$
BEGIN
    SELECT username, passwd FROM pg_catalog.pg_shadow
    WHERE username = i_username INTO uname, phash;
    RETURN;
END; $$ LANGUAGE plpgsql SECURITY DEFINER;
REVOKE ALL ON FUNCTION pgbouncer.user_lookup(text) FROM public, pgbouncer;
GRANT EXECUTE ON FUNCTION pgbouncer.user_lookup(text) TO pgbouncer;
```

Example configs for 2 peered pgbouncer processes to create a multi-core pgbouncer setup using [so_reuseport](#).

The config for the first process:

```
[databases]
postgres = host=localhost dbname=postgres
```

```
[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
unix_socket_dir=/tmp/pgbouncer1
peer_id=1
```

The config for the second process:

```
[databases]
postgres = host=localhost dbname=postgres

[peers]
1 = host=/tmp/pgbouncer1
2 = host=/tmp/pgbouncer2

[pgbouncer]
listen_addr=127.0.0.1
auth_file=auth_file.conf
so_reuseport=1
; only unix_socket_dir and peer_id are different
unix_socket_dir=/tmp/pgbouncer2
peer_id=2
```

pg_filedump

`pg_filedump` — display formatted contents of a Postgres Pro heap, index, or control file

Synopsis

```
pg_filedump [option...] [file]
```

Description

`pg_filedump` is a utility to format Postgres Pro heap/index/control files into a human-readable form. You can format/dump the files several ways, as listed in the [Options](#) section, as well as dump a straight binary. The type of file (heap/index) can usually be determined automatically by the content of the blocks within the file. However, to format a `pg_control` file you must use the `-c` option. The default is to format the entire file using the block size listed in block 0 and display block relative addresses. These defaults can be modified using run-time options. Some options may seem strange but they are there for a reason. For example, block size. It is there because if the header of block 0 is corrupt, you need a method of forcing a block size.

Installation

`pg_filedump` is provided with Postgres Pro as a separate pre-built package `pg-filedump-ent-13` (for the detailed installation instructions, see [Chapter 17](#)).

Options

Defaults are: relative addressing, range of the entire file, block size as listed on block 0 in the file.

The following options are valid for heap and index files:

- `-a`
Display absolute addresses when formatting. Block header information is always block-relative.
- `-b`
Display binary block images within a range. The option will turn off all formatting options.
- `-d`
Display formatted block content dump. The option will turn off all other formatting options.
- `-D attrlist`
Decode tuples using given comma-separated list of types. The list of supported types:
 - `bigint`
 - `bigserial`
 - `bool`
 - `char`
 - `charN — char(n)`
 - `date`
 - `float`
 - `float4`
 - `float8`
 - `int`
 - `json`
 - `macaddr`
 - `name`
 - `numeric`
 - `oid`
 - `real`

```

serial
smallint
smallserial
text
time
timestamp
timetz
uuid
varchar
varcharN — varchar(n)
xid
xml
~ — ignore all attributes left in a tuple

```

- f
Display formatted block content dump along with interpretation.
- h
Display help.
- i
Display interpreted item details.
- k
Verify block checksums.
- o
Do not dump old values.
- R *startblock* [*endblock*]
Display specific block ranges within the file. Blocks are indexed from 0. *startblock*: block to start at. *endblock*: block to end at. A *startblock* without an *endblock* will format a single block.
- s *segsize*
Force segment size to *segsize*.
- t
Dump TOAST files.
- v
Output additional information about TOAST relations.
- n *segnumber*
Force segment number to *segnumber*.
- S *blocksize*
Force block size to *blocksize*.
- x
Force interpreted formatting of block items as index items.
- y
Force interpreted formatting of block items as heap items.

The following options are valid for control files:

`-c`

Interpret the file listed as a control file.

`-f`

Display formatted content dump along with interpretation.

`-S blocksize`

Force block size to *blocksize*.

Additional parameters:

`-m`

Interpret file as `pg_filenode.map` file and print contents. All other options will be ignored.

In most cases, it is recommended to use the `-i` and `-f` options to get the most useful dump output.

pgpro_controldata

pgpro_controldata — display control information of a PostgreSQL/Postgres Pro database cluster and compatibility information for a cluster and/or server

Synopsis

```
pgpro_controldata [option...]
```

Description

pgpro_controldata prints control information, such as the catalog version, initialized by `initdb` command of any PostgreSQL/Postgres Pro server. It also shows information about write-ahead logging and checkpoint processing. This information is cluster-wide and not specific to any database.

pgpro_controldata also helps to check compatibility between PostgreSQL/Postgres Pro database servers and clusters. It can print server or cluster parameters that can affect the compatibility and check whether a cluster and server are compatible by comparing those parameters.

Options

pgpro_controldata accepts the following command-line arguments. If no arguments are specified, `pgpro_controldata` just prints the control information like [pg_controldata](#) does. Note that compatibility-related command-line arguments `-P` and `-S` specified together work the same way as `-C`.

General-Purpose

`-B`
`--bindir`
Specifies the PostgreSQL/Postgres Pro executable directory, needed to get server compatibility parameters.

`-D datadir`
`--pgdata=datadir`
Specifies the file system location of the database configuration files. If this option is omitted, the environment variable `PGDATA` is used.

`-V`
`--version`
Print the `pgpro_controldata` version, then exit.

`-?`
`--help`
Show help about `pgpro_controldata` command-line arguments, then exit.

Compatibility-Related

`-C`
`--compatibility-check`
Display all parameters that can affect compatibility between the specified server and cluster and check whether they are compatible.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

If the `-B` option is omitted, the current server is assumed.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-P`
`--cluster-compatibility-params`

Display all parameters of the specified cluster that can affect the compatibility.

Use the `-D` option or the environment variable `PGDATA` to provide the path to the data directory, where read access is required.

The cluster data and the server must have the same byte order and architecture type for this option to work correctly.

`-S`
`--server-compatibility-params`

Display all parameters of the specified or current server that can affect the compatibility.

If the `-B` option is omitted, the current server is assumed.

Environment

`PGDATA`
Default data directory location

`PG_COLOR`
Specifies whether to use color in diagnostic messages. Possible values are `always`, `auto` and `never`.

[pg_controldata](#)

pg_standby

`pg_standby` — supports the creation of a Postgres Pro warm standby server

Synopsis

```
pg_standby [option...] archivelocation nextwalfile walfilepath [restartwalfile]
```

Description

`pg_standby` supports creation of a “warm standby” database server. It is designed to be a production-ready program, as well as a customizable template should you require specific modifications.

`pg_standby` is designed to be a waiting `restore_command`, which is needed to turn a standard archive recovery into a warm standby operation. Other configuration is required as well, all of which is described in the main server manual (see [Section 26.2](#)).

To configure a standby server to use `pg_standby`, put this into its `postgresql.conf` configuration file:

```
restore_command = 'pg_standby archiveDir %f %p %r'
```

where *archiveDir* is the directory from which WAL segment files should be restored.

If *restartwalfile* is specified, normally by using the `%r` macro, then all WAL files logically preceding this file will be removed from *archivelocation*. This minimizes the number of files that need to be retained, while preserving crash-restart capability. Use of this parameter is appropriate if the *archivelocation* is a transient staging area for this particular standby server, but *not* when the *archivelocation* is intended as a long-term WAL archive area.

`pg_standby` assumes that *archivelocation* is a directory readable by the server-owning user. If *restartwalfile* (or `-k`) is specified, the *archivelocation* directory must be writable too.

There are two ways to fail over to a “warm standby” database server when the master server fails:

Smart Failover

In smart failover, the server is brought up after applying all WAL files available in the archive. This results in zero data loss, even if the standby server has fallen behind, but if there is a lot of unapplied WAL it can be a long time before the standby server becomes ready. To trigger a smart failover, create a trigger file containing the word `smart`, or just create it and leave it empty.

Fast Failover

In fast failover, the server is brought up immediately. Any WAL files in the archive that have not yet been applied will be ignored, and all transactions in those files are lost. To trigger a fast failover, create a trigger file and write the word `fast` into it. `pg_standby` can also be configured to execute a fast failover automatically if no new WAL file appears within a defined interval.

Options

`pg_standby` accepts the following command-line arguments:

- `-c`
Use `cp` or `copy` command to restore WAL files from archive. This is the only supported behavior so this option is useless.
- `-d`
Print lots of debug logging output on `stderr`.
- `-k`
Remove files from *archivelocation* so that no more than this many WAL files before the current one are kept in the archive. Zero (the default) means not to remove any files from *archivelocation*. This

parameter will be silently ignored if *restartwalfile* is specified, since that specification method is more accurate in determining the correct archive cut-off point. Use of this parameter is *deprecated* as of PostgreSQL 8.3; it is safer and more efficient to specify a *restartwalfile* parameter. A too small setting could result in removal of files that are still needed for a restart of the standby server, while a too large setting wastes archive space.

`-r maxretries`

Set the maximum number of times to retry the copy command if it fails (default 3). After each failure, we wait for *sleeptime* * *num_retries* so that the wait time increases progressively. So by default, we will wait 5 secs, 10 secs, then 15 secs before reporting the failure back to the standby server. This will be interpreted as end of recovery and the standby will come up fully as a result.

`-s sleeptime`

Set the number of seconds (up to 60, default 5) to sleep between tests to see if the WAL file to be restored is available in the archive yet. The default setting is not necessarily recommended; consult [Section 26.2](#) for discussion.

`-t triggerfile`

Specify a trigger file whose presence should cause failover. It is recommended that you use a structured file name to avoid confusion as to which server is being triggered when multiple servers exist on the same system; for example `/tmp/pgsql.trigger.5432`.

`-V`

`--version`

Print the `pg_standby` version and exit.

`-w maxwaittime`

Set the maximum number of seconds to wait for the next WAL file, after which a fast failover will be performed. A setting of zero (the default) means wait forever. The default setting is not necessarily recommended; consult [Section 26.2](#) for discussion.

`-?`

`--help`

Show help about `pg_standby` command line arguments, and exit.

Notes

`pg_standby` is designed to work with PostgreSQL 8.2 and later.

PostgreSQL 8.3 provides the `%r` macro, which is designed to let `pg_standby` know the last file it needs to keep. With PostgreSQL 8.2, the `-k` option must be used if archive cleanup is required. This option remains available in 8.3, but its use is deprecated.

PostgreSQL 8.4 provides the `recovery_end_command` option. Without this option a leftover trigger file can be hazardous.

`pg_standby` is written in C and has an easy-to-modify source code, with specifically designated sections to modify for your own needs

Examples

On Linux or Unix systems, you might use:

```
archive_command = 'cp %p .../archive/%f'
```

```
restore_command = 'pg_standby -d -s 2 -t /tmp/pgsql.trigger.5442 .../archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'rm -f /tmp/pgsql.trigger.5442'
```

where the archive directory is physically located on the standby server, so that the `archive_command` is accessing it across NFS, but the files are local to the standby (enabling use of `ln`). This will:

- produce debugging output in `standby.log`
- sleep for 2 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `/tmp/pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

On Windows, you might use:

```
archive_command = 'copy %p ...\\archive\\%f'
```

```
restore_command = 'pg_standby -d -s 5 -t C:\pgsql.trigger.5442 ...\\archive %f %p %r  
2>>standby.log'
```

```
recovery_end_command = 'del C:\pgsql.trigger.5442'
```

Note that backslashes need to be doubled in the `archive_command`, but *not* in the `restore_command` or `recovery_end_command`. This will:

- use the `copy` command to restore WAL files from archive
- produce debugging output in `standby.log`
- sleep for 5 seconds between checks for next WAL file availability
- stop waiting only when a trigger file called `C:\pgsql.trigger.5442` appears, and perform failover according to its content
- remove the trigger file when recovery ends
- remove no-longer-needed files from the archive directory

The `copy` command on Windows sets the final file size before the file is completely copied, which would ordinarily confuse `pg_standby`. Therefore `pg_standby` waits *sleep_time* seconds once it sees the proper file size. GNUWin32's `cp` sets the file size only after the file copy is complete.

Since the Windows example uses `copy` at both ends, either or both servers might be accessing the archive directory across the network.

[pg_archivecleanup](#)

pg_integrity_check

`pg_integrity_check` — calculate and validate checksums for controlled files (certified edition only)

Synopsis

```
pg_integrity_check [connection-option...] [-s | --system] [-u | --user] [-c | --catalog] [-o | --output]
[-l filename | --log=filename] [--syslog] [-D datadir] [-C filename] [-v | --verbose] [-? | --help]
```

Description

`pg_integrity_check` is a utility provided with Postgres Pro Enterprise that can calculate and validate checksums for the objects you would like to control. When running `pg_integrity_check`, you must specify at least one of the options that define the type of the controlled objects: `-s`, `-u`, or `-c` for read-only files, additional files, or system catalog tables, respectively.

If you use the `-o` option, `pg_integrity_check` calculates checksums and writes them into configuration files under the `share/security/` directory. You must have write access to the corresponding files to perform this command. You cannot use the `-o` option together with the `-s` option, since a checksum for read-only files cannot be overwritten.

If you omit the `-o` option, `pg_integrity_check` compares the calculated checksums with the corresponding checksums in the configuration files. If the checksums differ for any of the controlled objects, `pg_integrity_check` displays a message indicating the difference.

For details on using `pg_integrity_check`, see [Section 34.2](#).

Options

connection-options

Standard options for connecting to a database: `-d`, `-h`, `-p`, `-U`. You must specify `-d` and `-U` options when validating checksums for catalog tables with the `-c` option. For detailed description of connection options, see [psql](#).

`-s`
`--system`

Validate checksums for read-only files. Checksums for read-only files control both file contents and file attributes.

`-u`
`--user`

Validate checksums for additional files. Checksums for additional files control both file contents and file attributes.

`-c`
`--catalog`

Validate checksums for system catalog tables. For the `-c` option to work correctly, you must also specify connection parameters for the database. The database server must be started and accept connections.

`-o`
`--output`

Recalculate checksums and write it into a file.

`-l filename`
`--log=filename`

Write checksum validation results into a log file.

`--syslog`

Write checksum validation results into the syslog.

`-D datadir`

Data directory of the database cluster. This option is required to define the filenames for the generated configuration files when using `-u` option.

`-C filename`

The absolute path to the configuration file used for integrity checks of system catalog tables of the selected database. If used with the `-o` option, `pg_integrity_check` writes into the specified file. If no other option is used, `pg_integrity_check` checks data against the specified file.

`-v`

`--verbose`

Print debugging information.

`-?`

`--help`

Print command-line help.

Return Values

0 — checksums are calculated or validated successfully.

1 — an error occurred during the initial checksum calculation for read-only files.

2 — checksum validation revealed changes in one or more of the controlled objects.

3 — an unexpected error occurred during checksum validation.

Examples

Compute checksums for additional files and write them into the `share/security/_var_lib_pgpro_ent-13_data.user.conf` configuration file:

```
pg_integrity_check -u -o -D /var/lib/pgpro/ent-13/data
```

Check integrity of all controlled objects in the `postgres` database on behalf of the `postgres` user:

```
pg_integrity_check -s -u -c -D /var/lib/pgpro/ent-13/data -d postgres -h localhost -p  
5432 -U postgres
```

Appendix H. External Projects

Postgres Pro is a complex software project, and managing the project is difficult. We have found that many enhancements to Postgres Pro can be more efficiently developed separately from the core project.

H.1. Client Interfaces

There are only two client interfaces included in the base Postgres Pro Enterprise distribution:

- [libpq](#) is included because it is the primary C language interface, and because many other client interfaces are built on top of it.
- [ECPG](#) is included because it depends on the server-side SQL grammar, and is therefore sensitive to changes in Postgres Pro itself.

All other language interfaces are external projects and are distributed separately. A [list of language interfaces](#) is maintained on the PostgreSQL wiki. Note that some of these packages are not released under the same license as Postgres Pro. For more information on each language interface, including licensing terms, refer to its website and documentation.

https://wiki.postgresql.org/wiki/List_of_drivers

H.2. Administration Tools

There are several administration tools available for Postgres Pro. One of them is PPEM, an integrated administration panel for Postgres Pro Enterprise management. It provides centralized privilege-based access to a unified management and monitoring interface with embedded command line. There are other solutions, e.g. an open-source platform [pgAdmin](#).

H.3. Procedural Languages

Postgres Pro includes several procedural languages with the base distribution: [PL/pgSQL](#), [PL/Tcl](#), [PL/Perl](#), and [PL/Python](#).

In addition, there are a number of procedural languages that are developed and maintained outside the core Postgres Pro distribution. A list of [procedural languages](#) is maintained on the PostgreSQL wiki. Note that some of these projects are not released under the same license as Postgres Pro. For more information on each procedural language, including licensing information, refer to its website and documentation.

https://wiki.postgresql.org/wiki/PL_Matrix

H.4. Extensions

Postgres Pro is designed to be easily extensible. For this reason, extensions loaded into the database can function just like features that are built in. The extensions shipped with Postgres Pro are described in [Appendix F](#). Other extensions are developed independently, like [PostGIS](#). Even Postgres Pro replication solutions can be developed externally. For example, [Slony-I](#) is a popular master/standby replication solution that is developed independently from the core project.

Appendix I. Configuring Postgres Pro for 1C Solutions

You can install and use Postgres Pro with 1C solutions in a client/server model.

Make sure that the Russian locale (such as `ru_RU.UTF-8` on Linux systems) is installed and that it is the active locale of the user who creates the database cluster. For example, for Debian systems do the following:

```
sudo dpkg-reconfigure locales # Choose locale ru_RU.UTF-8 to generate
export LANG="ru_RU.UTF-8"
/opt/pgpro/ent-13/bin/pg-setup initdb
```

For more details, see related sections of the documentation for your operating system and for 1C.

Also, for optimal performance and stability, modify the following settings in the `postgresql.conf` configuration file of Postgres Pro server:

1. Increase the maximum number of allowed concurrent connections to the database server, up to 1000 connections. 1C solutions can open a large number of connections, even if not all of them are used, so it is recommended to allow not less than 500 connections.

```
max_connections = 1000
```

2. To ensure that temporary tables are handled correctly, modify the following parameters:

- Increase the buffer size for temporary tables:

```
temp_buffers = 32MB
```

- Increase the number of allowed locks of tables or indexes per transaction to 256:

```
max_locks_per_transaction = 256
```

Typically, 1C solutions use a lot of temporary tables. Every backend process usually contains multiple temporary tables. When closing a connection, Postgres Pro tries to drop all temporary tables in a single transaction, so this transaction may use a lot of locks. If the number of locks exceeds the `max_locks_per_transaction` value, the transaction will fail, leaving multiple orphaned temporary tables.

3. Enable backslash escapes in all strings, and switch off the warning about using the backslash escape symbol:

```
standard_conforming_strings = off
escape_string_warning = off
```

4. Set the `effective_cache_size` parameter to at least half of RAM available on the system. Postgres Pro query optimizer performance depends on the amount of allocated RAM.

5. Optimize query planning using [plantuner](#) extension, as follows:

- Add `plantuner` to the `shared_preload_libraries` variable:

```
shared_preload_libraries = 'plantuner'
```

- Tune Postgres Pro optimizer to improve planning for recently created empty tables:

```
plantuner.fix_empty_table = 'on'
```

Appendix J. Postgres Pro Limits

Table J.1 describes various hard limits of Postgres Pro. However, practical limits, such as performance limitations or available disk space may apply before absolute hard limits are reached.

Table J.1. Postgres Pro Limitations

Item	Upper Limit	Comment
database size	unlimited	
number of databases	4,294,950,911	
relations per database	1,431,650,303	
relation size	32 TB	with the default <code>BLCKSZ</code> of 8192 bytes
rows per table	limited by the number of tuples that can fit onto 4,294,967,295 pages	
columns per table	1,600	further limited by tuple size fitting on a single page; see note below
columns in a result set	1,664	
field size	1 GB	
indexes per table	unlimited	constrained by maximum relations per database
columns per index	32	can be increased by recompiling Postgres Pro
partition keys	32	can be increased by recompiling Postgres Pro
identifier length	63 bytes	can be increased by recompiling Postgres Pro
function arguments	100	can be increased by recompiling Postgres Pro
query parameters	65,535	

The maximum number of columns for a table is further reduced as the tuple being stored must fit in a single 8192-byte heap page. For example, excluding the tuple header, a tuple made up of 1,600 `int` columns would consume 6400 bytes and could be stored in a heap page, but a tuple of 1,600 `bigint` columns would consume 12800 bytes and would therefore not fit inside a heap page. Variable-length fields of types such as `text`, `varchar`, and `char` can have their values stored out of line in the table's TOAST table when the values are large enough to require it. Only an 18-byte pointer must remain inside the tuple in the table's heap. For shorter length variable-length fields, either a 4-byte or 1-byte field header is used and the value is stored inside the heap tuple.

Columns that have been dropped from the table also contribute to the maximum column limit. Moreover, although the dropped column values for newly created tuples are internally marked as null in the tuple's null bitmap, the null bitmap also occupies space.

Appendix K. Demo Database

“Airlines”

This is an overview of a demo database for Postgres Pro. This appendix describes the database schema, which consists of eight tables and several views. The subject field of this database is airline flights in Russia. You can download the database from [our website](#). See [Section K.1](#) for details.

Figure K.1. Airlines in Russia

You can use this database for various purposes, such as:

- learning SQL language on your own
- preparing books, manuals, and courses on SQL
- showing Postgres Pro features in stories and articles

When developing this demo database, we pursued several goals:

- Database schema must be simple enough to be understood without extra explanations.
- At the same time, database schema must be complex enough to allow writing meaningful queries.
- The database must contain true-to-life data that will be interesting to work with.

This demo database is distributed under the [PostgreSQL license](#).

You can send us your feedback to edu@postgrespro.ru.

K.1. Installation

The demo database is available at edu.postgrespro.com in three flavors, which differ only in the data size:

- [demo-small-en.zip](#) (21 MB) — flight data for one month (DB size is about 300 MB)
- [demo-medium-en.zip](#) (62 MB) — flight data for three months (DB size is about 700 MB)
- [demo-big-en.zip](#) (232 MB) — flight data for one year (DB size is about 2.5 GB)

The small database is good for writing queries, and it will not take up much disk space. The large database can help you understand the query behavior on large data volumes and consider query optimization.

The files include an SQL script that creates the `demo` database and fills it with data (virtually, it is a backup copy created with the `pg_dump` utility). The owner of the `demo` database will be the DBMS user who runs the script. For example, to create the small database, run the script as the user `postgres` by means of `psql`:

```
psql -f demo_small_YYYYMMDD.sql -U postgres
```

Note that if the `demo` database already exists, it will be deleted and recreated!

K.2. Schema Diagram

Figure K.2. Bookings Schema Diagram

K.3. Schema Description

The main entity is a booking (`bookings`).

One booking can include several passengers, with a separate ticket (`tickets`) issued to each passenger. A ticket has a unique number and includes information about the passenger. As such, the passenger is not a separate entity. Both the passenger's name and identity document number can change over time, so it is impossible to uniquely identify all the tickets of a particular person; for simplicity, we can assume that all passengers are unique.

The ticket includes one or more flight segments (`ticket_flights`). Several flight segments can be included into a single ticket if there are no non-stop flights between the points of departure and destination (connecting flights), or if it is a round-trip ticket. Although there is no constraint in the schema, it is assumed that all tickets in the booking have the same flight segments.

Each flight (`flights`) goes from one airport (`airports`) to another. Flights with the same flight number have the same points of departure and destination, but differ in departure date.

At flight check-in, the passenger is issued a boarding pass (`boarding_passes`), where the seat number is specified. The passenger can check in for the flight only if this flight is included into the ticket. The flight-seat combination must be unique to avoid issuing two boarding passes for the same seat.

The number of seats (`seats`) in the aircraft and their distribution between different travel classes depends on the model of the aircraft (`aircrafts`) performing the flight. It is assumed that every aircraft model has only one cabin configuration. Database schema does not check that seat numbers in boarding passes have the corresponding seats in the aircraft (such verification can be done using table triggers, or at the application level).

K.4. Schema Objects

K.4.1. List of Relations

Name	Type	Small	Medium	Big	Description
<code>aircrafts</code>	view				Aircraft
<code>aircrafts_data</code>	table	16 kB	16 kB	16 kB	Aircraft (translations)
<code>airports</code>	view				Airports
<code>airports_data</code>	table	56 kB	56 kB	56 kB	Airports (translations)
<code>boarding_passes</code>	table	31 MB	102 MB	427 MB	Boarding passes
<code>bookings</code>	table	13 MB	30 MB	105 MB	Bookings
<code>flights</code>	table	3 MB	6 MB	19 MB	Flights
<code>flights_v</code>	view				Flights
<code>routes</code>	view				Routes
<code>seats</code>	table	88 kB	88 kB	88 kB	Seats
<code>ticket_flights</code>	table	64 MB	145 MB	516 MB	Flight segments
<code>tickets</code>	table	47 MB	107 MB	381 MB	Tickets

K.4.2. View `bookings.aircrafts`

Each aircraft model is identified by its three-digit code (`aircraft_code`). The view also includes the name of the aircraft model (`model`) and the maximal flying distance, in kilometers (`range`).

The value of the `model` field is selected according to the chosen language. See [Section K.4.15](#) for details.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA
<code>model</code>	<code>text</code>	<code>not null</code>	Aircraft model
<code>range</code>	<code>integer</code>	<code>not null</code>	Maximal flying distance, km

View definition:

```
SELECT ml.aircraft_code,
       ml.model ->> lang() AS model,
       ml.range
FROM   aircrafts_data ml;
```

K.4.3. Table `bookings.aircrafts_data`

This is the base table for the `aircrafts` view. The `model` field of this table contains translations of aircraft models to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

Column	Type	Modifiers	Description
<code>aircraft_code</code>	<code>char(3)</code>	<code>not null</code>	Aircraft code, IATA

```

model          | jsonb   | not null    | Aircraft model
range          | integer | not null    | Maximal flying distance, km

```

Indexes:

```
PRIMARY KEY, btree (aircraft_code)
```

Check constraints:

```
CHECK (range > 0)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code)
TABLE "seats" FOREIGN KEY (aircraft_code)
REFERENCES aircrafts_data(aircraft_code) ON DELETE CASCADE

```

K.4.4. View `bookings.airports`

An airport is identified by a three-letter code (`airport_code`) and has a name (`airport_name`).

There is no separate entity for the city, but there is a city name (`city`) to identify the airports of the same city. The view also includes coordinates (`coordinates`) and the time zone (`timezone`).

The values of the `airport_name` and `city` fields are selected according to the chosen language. See [Section K.4.15](#) for details.

Column	Type	Modifiers	Description
<code>airport_code</code>	<code>char(3)</code>	<code>not null</code>	Airport code
<code>airport_name</code>	<code>text</code>	<code>not null</code>	Airport name
<code>city</code>	<code>text</code>	<code>not null</code>	City
<code>coordinates</code>	<code>point</code>	<code>not null</code>	Airport coordinates (longitude and latitude)
<code>timezone</code>	<code>text</code>	<code>not null</code>	Airport time zone

View definition:

```

SELECT ml.airport_code,
       ml.airport_name ->> lang() AS airport_name,
       ml.city ->> lang() AS city,
       ml.coordinates,
       ml.timezone
FROM airports_data ml;

```

K.4.5. Table `bookings.airports_data`

This is the base table for the `airports` view. This table contains translations of `airport_name` and `city` values to different languages, in the JSONB format. In most cases, this table is not supposed to be used directly.

Column	Type	Modifiers	Description
<code>airport_code</code>	<code>char(3)</code>	<code>not null</code>	Airport code
<code>airport_name</code>	<code>jsonb</code>	<code>not null</code>	Airport name
<code>city</code>	<code>jsonb</code>	<code>not null</code>	City
<code>coordinates</code>	<code>point</code>	<code>not null</code>	Airport coordinates (longitude and latitude)
<code>timezone</code>	<code>text</code>	<code>not null</code>	Airport time zone

Indexes:

```
PRIMARY KEY, btree (airport_code)
```

Referenced by:

```

TABLE "flights" FOREIGN KEY (arrival_airport)
REFERENCES airports_data(airport_code)
TABLE "flights" FOREIGN KEY (departure_airport)
REFERENCES airports_data(airport_code)

```

K.4.6. Table `bookings.boarding_passes`

At the time of check-in, which opens twenty-four hours before the scheduled departure, the passenger is issued a boarding pass. Like the flight segment, the boarding pass is identified by the ticket number and the flight number.

Boarding passes are assigned sequential numbers (`boarding_no`), in the order of check-ins for the flight (this number is unique only within the context of a particular flight). The boarding pass specifies the seat number (`seat_no`).

Column	Type	Modifiers	Description
<code>ticket_no</code>	<code>char(13)</code>	<code>not null</code>	Ticket number
<code>flight_id</code>	<code>integer</code>	<code>not null</code>	Flight ID
<code>boarding_no</code>	<code>integer</code>	<code>not null</code>	Boarding pass number
<code>seat_no</code>	<code>varchar(4)</code>	<code>not null</code>	Seat number

Indexes:

```
PRIMARY KEY, btree (ticket_no, flight_id)
UNIQUE CONSTRAINT, btree (flight_id, boarding_no)
UNIQUE CONSTRAINT, btree (flight_id, seat_no)
```

Foreign-key constraints:

```
FOREIGN KEY (ticket_no, flight_id)
REFERENCES ticket_flights(ticket_no, flight_id)
```

K.4.7. Table `bookings.bookings`

Passengers book tickets for themselves, and, possibly, for several other passengers, in advance (`book_date`, not earlier than one month before the flight). The booking is identified by its number (`book_ref`, a six-position combination of letters and digits).

The `total_amount` field stores the total cost of all tickets included into the booking, for all passengers.

Column	Type	Modifiers	Description
<code>book_ref</code>	<code>char(6)</code>	<code>not null</code>	Booking number
<code>book_date</code>	<code>timestampz</code>	<code>not null</code>	Booking date
<code>total_amount</code>	<code>numeric(10,2)</code>	<code>not null</code>	Total booking cost

Indexes:

```
PRIMARY KEY, btree (book_ref)
```

Referenced by:

```
TABLE "tickets" FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
```

K.4.8. Table `bookings.flights`

The natural key of the `bookings.flights` table consists of two fields — `flight_no` and `scheduled_departure`. To make foreign keys for this table more compact, a surrogate key is used as the primary key (`flight_id`).

A flight always connects two points — the airport of departure (`departure_airport`) and arrival (`arrival_airport`). There is no such entity as a “connecting flight”: if there are no non-stop flights from one airport to another, the ticket simply includes several required flight segments.

Each flight has a scheduled date and time of departure (`scheduled_departure`) and arrival (`scheduled_arrival`). The actual departure time (`actual_departure`) and arrival time (`actual_arrival`) can differ: the difference is usually not very big, but sometimes can be up to several hours if the flight is delayed.

Flight status (*status*) can take one of the following values:

Scheduled

The flight is available for booking. It happens one month before the planned departure date; before that time, there is no entry for this flight in the database.

On Time

The flight is open for check-in (in twenty-four hours before the scheduled departure) and is not delayed.

Delayed

The flight is open for check-in (in twenty-four hours before the scheduled departure) but is delayed.

Departed

The aircraft has already departed and is airborne.

Arrived

The aircraft has reached the point of destination.

Cancelled

The flight is canceled.

Column	Type	Modifiers	Description
flight_id	serial	not null	Flight ID
flight_no	char(6)	not null	Flight number
scheduled_departure	timestampz	not null	Scheduled departure time
scheduled_arrival	timestampz	not null	Scheduled arrival time
departure_airport	char(3)	not null	Airport of departure
arrival_airport	char(3)	not null	Airport of arrival
status	varchar(20)	not null	Flight status
aircraft_code	char(3)	not null	Aircraft code, IATA
actual_departure	timestampz		Actual departure time
actual_arrival	timestampz		Actual arrival time

Indexes:

PRIMARY KEY, btree (flight_id)
 UNIQUE CONSTRAINT, btree (flight_no, scheduled_departure)

Check constraints:

CHECK (scheduled_arrival > scheduled_departure)
 CHECK ((actual_arrival IS NULL)
 OR ((actual_departure IS NOT NULL AND actual_arrival IS NOT NULL)
 AND (actual_arrival > actual_departure)))
 CHECK (status IN ('On Time', 'Delayed', 'Departed',
 'Arrived', 'Scheduled', 'Cancelled'))

Foreign-key constraints:

FOREIGN KEY (aircraft_code)
 REFERENCES aircrafts(aircraft_code)
 FOREIGN KEY (arrival_airport)
 REFERENCES airports(airport_code)
 FOREIGN KEY (departure_airport)
 REFERENCES airports(airport_code)

Referenced by:

TABLE "ticket_flights" FOREIGN KEY (flight_id)
 REFERENCES flights(flight_id)

K.4.9. Table bookings.seats

Seats define the cabin configuration of each aircraft model. Each seat is defined by its number (`seat_no`) and has an assigned travel class (`fare_conditions`): Economy, Comfort or Business.

Column	Type	Modifiers	Description
aircraft_code	char(3)	not null	Aircraft code, IATA
seat_no	varchar(4)	not null	Seat number
fare_conditions	varchar(10)	not null	Travel class

Indexes:

PRIMARY KEY, btree (aircraft_code, seat_no)

Check constraints:

CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))

Foreign-key constraints:

FOREIGN KEY (aircraft_code)

REFERENCES aircrafts(aircraft_code) ON DELETE CASCADE

K.4.10. Table bookings.ticket_flights

A flight segment connects a ticket with a flight and is identified by their numbers.

Each flight has its cost (`amount`) and travel class (`fare_conditions`).

Column	Type	Modifiers	Description
ticket_no	char(13)	not null	Ticket number
flight_id	integer	not null	Flight ID
fare_conditions	varchar(10)	not null	Travel class
amount	numeric(10,2)	not null	Travel cost

Indexes:

PRIMARY KEY, btree (ticket_no, flight_id)

Check constraints:

CHECK (amount >= 0)

CHECK (fare_conditions IN ('Economy', 'Comfort', 'Business'))

Foreign-key constraints:

FOREIGN KEY (flight_id) REFERENCES flights(flight_id)

FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)

Referenced by:

TABLE "boarding_passes" FOREIGN KEY (ticket_no, flight_id)

REFERENCES ticket_flights(ticket_no, flight_id)

K.4.11. Table bookings.tickets

A ticket has a unique number (`ticket_no`) that consists of 13 digits.

The ticket includes a passenger ID (`passenger_id`) — the identity document number, — their first and last names (`passenger_name`), and contact information (`contact_data`).

Neither the passenger ID, nor the name is permanent (for example, one can change the last name or passport), so it is impossible to uniquely identify all tickets of a particular passenger.

Column	Type	Modifiers	Description
ticket_no	char(13)	not null	Ticket number
book_ref	char(6)	not null	Booking number
passenger_id	varchar(20)	not null	Passenger ID
passenger_name	text	not null	Passenger name

```

contact_data | jsonb | Passenger contact information
Indexes:
PRIMARY KEY, btree (ticket_no)
Foreign-key constraints:
FOREIGN KEY (book_ref) REFERENCES bookings(book_ref)
Referenced by:
TABLE "ticket_flights" FOREIGN KEY (ticket_no) REFERENCES tickets(ticket_no)

```

K.4.12. View bookings.flights_v

There is a `flights_v` view over the `flights` table that provides additional information:

- Details about the airport of departure — `departure_airport`, `departure_airport_name`, `departure_city`
- Details about the airport of arrival — `arrival_airport`, `arrival_airport_name`, `arrival_city`
- Local departure time — `scheduled_departure_local`, `actual_departure_local`
- Local arrival time — `scheduled_arrival_local`, `actual_arrival_local`
- Flight duration — `scheduled_duration`, `actual_duration`.

Column	Type	Description
<code>flight_id</code>	<code>integer</code>	Flight ID
<code>flight_no</code>	<code>char(6)</code>	Flight number
<code>scheduled_departure</code>	<code>timestamp</code>	Scheduled departure time
<code>scheduled_departure_local</code>	<code>timestamp</code>	Scheduled departure time, local time at the point of departure
<code>scheduled_arrival</code>	<code>timestamp</code>	Scheduled arrival time
<code>scheduled_arrival_local</code>	<code>timestamp</code>	Scheduled arrival time, local time at the point of destination
<code>scheduled_duration</code>	<code>interval</code>	Scheduled flight duration
<code>departure_airport</code>	<code>char(3)</code>	Departure airport code
<code>departure_airport_name</code>	<code>text</code>	Departure airport name
<code>departure_city</code>	<code>text</code>	City of departure
<code>arrival_airport</code>	<code>char(3)</code>	Arrival airport code
<code>arrival_airport_name</code>	<code>text</code>	Arrival airport name
<code>arrival_city</code>	<code>text</code>	City of arrival
<code>status</code>	<code>varchar(20)</code>	Flight status
<code>aircraft_code</code>	<code>char(3)</code>	Aircraft code, IATA
<code>actual_departure</code>	<code>timestamp</code>	Actual departure time
<code>actual_departure_local</code>	<code>timestamp</code>	Actual departure time, local time at the point of departure
<code>actual_arrival</code>	<code>timestamp</code>	Actual arrival time
<code>actual_arrival_local</code>	<code>timestamp</code>	Actual arrival time, local time at the point of destination
<code>actual_duration</code>	<code>interval</code>	Actual flight duration

K.4.13. View bookings.routes

The `bookings.flights` table contains some redundancies, which you can use to single out route information (flight number, airports of departure and destination) that does not depend on the exact flight dates.

Such information is shown in the `routes` view.

Column	Type	Description

flight_no	char(6)	Flight number
departure_airport	char(3)	Departure airport code
departure_airport_name	text	Departure airport name
departure_city	text	City of departure
arrival_airport	char(3)	Arrival airport code
arrival_airport_name	text	Arrival airport name
arrival_city	text	City of arrival
aircraft_code	char(3)	Aircraft code, IATA
duration	interval	Flight duration
days_of_week	integer[]	Days of the week on which flights are performed

K.4.14. Function `bookings.now`

The demo database contains “snapshots” of data — similar to a backup copy of a real system captured at some point in time. For example, if a flight has the `Departed` status, it means that the aircraft had already departed and was airborne at the time of the backup copy.

The “snapshot” time is saved in the `bookings.now()` function. You can use this function in demo queries for cases where you would use the `now()` function in a real database.

In addition, the return value of this function determines the version of the demo database. The latest version available is of August 15, 2017.

K.4.15. Function `bookings.lang`

Some fields in the demo database are available in English and Russian. Translations to other languages are not provided, but are easy to add. The `bookings.lang` returns the value of the `bookings.lang` parameter, that is, the language in which these fields will be displayed.

This function is used in the `aircrafts` and `airports` views and is not intended to be used directly in queries.

K.5. Usage

K.5.1. Schema `bookings`

The `bookings` schema contains all objects of the demo database. When you connect to the database, `search_path` configuration parameter is automatically set to `bookings, public`, so you do not need to specify the schema name explicitly.

However, for the `bookings.now` function, you always have to specify the schema to distinguish this function from the standard `now` function.

K.5.2. Translations

By default, values of several translatable fields are shown in Russian. These are `airport_name` and `city` of the `airports` view, as well as `model` of the `aircrafts` view.

You can choose to display these fields in another language (although only the English translation is provided in the demo database). To switch to English, set the `bookings.lang` parameter to `en`. It may be convenient to choose the language at the database level:

```
ALTER DATABASE demo SET bookings.lang = en;
```

You have to reconnect to the database for this command to take effect. For other methods of settings configuration parameters, see [Section 19.1](#).

In the examples below, the English language is selected for translatable fields.

K.5.3. Sample Queries

To better understand the contents of the demo database, let's take a look at the results of several simple queries.

The results displayed below were received on a small database version (demo-small) of August 15, 2017. If the same queries return different data on your system, check your demo database version (using the `bookings.now` function). Some minor deviations may be caused by the difference between your local time and Moscow time, or your locale settings.

All flights are operated by several types of aircraft:

```
SELECT * FROM aircrafts;
```

aircraft_code	model	range
773	Boeing 777-300	11100
763	Boeing 767-300	7900
SU9	Sukhoi SuperJet-100	3000
320	Airbus A320-200	5700
321	Airbus A321-200	5600
319	Airbus A319-100	6700
733	Boeing 737-300	4200
CN1	Cessna 208 Caravan	1200
CR2	Bombardier CRJ-200	2700

(9 rows)

For each aircraft type, a separate list of seats is supported. For example, in a small Cessna 208 Caravan, one can select the following seats:

```
SELECT  a.aircraft_code,
        a.model,
        s.seat_no,
        s.fare_conditions
FROM    aircrafts a
        JOIN seats s ON a.aircraft_code = s.aircraft_code
WHERE   a.model = 'Cessna 208 Caravan'
ORDER BY s.seat_no;
```

aircraft_code	model	seat_no	fare_conditions
CN1	Cessna 208 Caravan	1A	Economy
CN1	Cessna 208 Caravan	1B	Economy
CN1	Cessna 208 Caravan	2A	Economy
CN1	Cessna 208 Caravan	2B	Economy
CN1	Cessna 208 Caravan	3A	Economy
CN1	Cessna 208 Caravan	3B	Economy
CN1	Cessna 208 Caravan	4A	Economy
CN1	Cessna 208 Caravan	4B	Economy
CN1	Cessna 208 Caravan	5A	Economy
CN1	Cessna 208 Caravan	5B	Economy
CN1	Cessna 208 Caravan	6A	Economy
CN1	Cessna 208 Caravan	6B	Economy

(12 rows)

Bigger aircraft have more seats of various travel classes:

```
SELECT  s2.aircraft_code,
```

```

        string_agg (s2.fare_conditions || '(' || s2.num::text || ')',
                    ', ') as fare_conditions
FROM      (
        SELECT    s.aircraft_code, s.fare_conditions, count(*) as num
        FROM      seats s
        GROUP BY  s.aircraft_code, s.fare_conditions
        ORDER BY  s.aircraft_code, s.fare_conditions
        ) s2
GROUP BY  s2.aircraft_code
ORDER BY  s2.aircraft_code;
```

aircraft_code	fare_conditions
319	Business (20), Economy (96)
320	Business (20), Economy (120)
321	Business (28), Economy (142)
733	Business (12), Economy (118)
763	Business (30), Economy (192)
773	Business (30), Comfort (48), Economy (324)
CN1	Economy (12)
CR2	Economy (50)
SU9	Business (12), Economy (85)

(9 rows)

The demo database contains the list of airports of almost all major Russian cities. Most cities have only one airport. The exceptions are:

```

SELECT    a.airport_code as code,
          a.airport_name,
          a.city,
          a.coordinates
FROM      airports a
WHERE     a.city IN (
          SELECT    aa.city
          FROM      airports aa
          GROUP BY  aa.city
          HAVING    COUNT(*) > 1
          )
ORDER BY  a.city, a.airport_code;
```

code	airport_name	city	coordinates
DME	Domodedovo	Moscow	(37.9062995910645, 55.4087982177734)
	International Airport		
SVO	Sheremetyevo	Moscow	(37.4146, 55.972599)
	International Airport		
VKO	Vnukovo	Moscow	(37.2615013123, 55.5914993286)
	International Airport		
ULV	Ulyanovsk	Ulyanovsk	(48.2266998291, 54.2682991028)
	Baratayevka Airport		
ULY	Ulyanovsk East Airport	Ulyanovsk	(48.8027000427246, 54.4010009765625)

(5 rows)

To learn about your flying options from one point to another, it is convenient to use the `routes` materialized view that aggregates information on all flights. For example, here are the destinations where you can get from Volgograd on specific days of the week, with flight duration:

```
SELECT r.arrival_city as city,
       r.arrival_airport as code,
       r.arrival_airport_name as airport_name,
       r.days_of_week,
       r.duration
FROM   routes r
WHERE  r.departure_city = 'Volgograd';
```

city	code	airport_name	days_of_week	duration
Moscow	SVO	Sheremetyevo International Airport	{1,2,3,4,5,6,7}	01:15:00
Chelyabinsk	CEK	Chelyabinsk Balandino Airport	{1,2,3,4,5,6,7}	01:50:00
Rostov	ROV	Rostov-on-Don Airport	{1,2,3,4,5,6,7}	00:30:00
Moscow	VKO	Vnukovo International Airport	{1,2,3,4,5,6,7}	01:10:00
Cheboksary	CSY	Cheboksary Airport	{1,2,3,4,5,6,7}	02:45:00
Tomsk	TOF	Bogashevo Airport	{1}	03:50:00

(6 rows)

The database was formed at the moment returned by the `bookings.now()` function:

```
SELECT bookings.now() as now;
```

now
2017-08-15 18:00:00+03

In relation to this moment, all flights are classified as past and future flights:

```
SELECT  status,
        count(*) as count,
        min(scheduled_departure) as min_scheduled_departure,
        max(scheduled_departure) as max_scheduled_departure
FROM    flights
GROUP BY status
ORDER BY min_scheduled_departure;
```

status	count	min_scheduled_departure	max_scheduled_departure
Arrived	16707	2017-07-16 01:50:00+03	2017-08-15 17:25:00+03
Cancelled	414	2017-07-19 11:35:00+03	2017-09-14 20:55:00+03
Departed	58	2017-08-15 09:55:00+03	2017-08-15 17:50:00+03
Delayed	41	2017-08-15 15:15:00+03	2017-08-16 17:25:00+03
On Time	518	2017-08-15 17:55:00+03	2017-08-16 18:00:00+03
Scheduled	15383	2017-08-16 18:05:00+03	2017-09-14 20:40:00+03

(6 rows)

Let's find the next flight from Yekaterinburg to Moscow. The `flight` table is not very convenient for such queries, as it does not include information on the cities of departure and arrival. That is why we will use the `flights_v` view:

```
\x
SELECT  f.*
FROM    flights_v f
WHERE    f.departure_city = 'Yekaterinburg'
AND      f.arrival_city = 'Moscow'
```

```
AND      f.scheduled_departure > bookings.now()
ORDER BY f.scheduled_departure
LIMIT    1;
```

```
-[ RECORD 1 ]-----+-----
flight_id      | 10927
flight_no      | PG0226
scheduled_departure | 2017-08-16 08:10:00+03
scheduled_departure_local | 2017-08-16 10:10:00
scheduled_arrival | 2017-08-16 09:55:00+03
scheduled_arrival_local | 2017-08-16 09:55:00
scheduled_duration | 01:45:00
departure_airport | SVX
departure_airport_name | Koltsovo Airport
departure_city | Yekaterinburg
arrival_airport | SVO
arrival_airport_name | Sheremetyevo International Airport
arrival_city | Moscow
status | On Time
aircraft_code | 773
actual_departure |
actual_departure_local |
actual_arrival |
actual_arrival_local |
actual_duration |
```

Note that the `flights_v` view shows both Moscow time and local time at the airports of departure and arrival.

K.5.4. Bookings

Each booking can include several tickets, one for each passenger. The ticket, in its turn, can include several flight segments. The complete information about the booking is stored in three tables: `bookings`, `tickets`, and `ticket_flights`.

Let's find several most expensive bookings:

```
SELECT *
FROM bookings
ORDER BY total_amount desc
LIMIT 10;
```

book_ref	book_date	total_amount
3B54BB	2017-07-05 17:08:00+03	1204500.00
3AC131	2017-07-31 01:06:00+03	1087100.00
65A6EA	2017-07-03 06:28:00+03	1065600.00
D7E9AA	2017-08-08 05:29:00+03	1062800.00
EF479E	2017-08-02 15:58:00+03	1035100.00
521C53	2017-07-08 09:25:00+03	985500.00
514CA6	2017-07-27 05:07:00+03	955000.00
D70BD9	2017-07-05 12:47:00+03	947500.00
EC7EDA	2017-07-02 16:13:00+03	946800.00
8E4370	2017-07-28 02:04:00+03	945700.00

(10 rows)

Let's take a look at the tickets included into the booking with code 521C53:

```
SELECT ticket_no,
       passenger_id,
       passenger_name
FROM   tickets
WHERE  book_ref = '521C53';
```

ticket_no	passenger_id	passenger_name
0005432661914	8234 547529	IVAN IVANOV
0005432661915	2034 201228	ANTONINA KUZNECOVA

(2 rows)

If we would like to know, which flight segments are included into Antonina Kuznecova's ticket, we can use the following query:

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        tf.fare_conditions AS class,
        tf.amount
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

when	departure	arrival	class	amount
29.07.2017	Moscow (SVO)	Anadyr (DYR)	Business	185300.00
02.08.2017	Anadyr (DYR)	Khabarovsk (KHV)	Business	92200.00
03.08.2017	Khabarovsk (KHV)	Blagoveshchensk (BQS)	Business	18000.00
08.08.2017	Blagoveshchensk (BQS)	Khabarovsk (KHV)	Business	18000.00
12.08.2017	Khabarovsk (KHV)	Anadyr (DYR)	Economy	30700.00
17.08.2017	Anadyr (DYR)	Moscow (SVO)	Business	185300.00

(6 rows)

As we can see, high booking cost is explained by multiple long-haul flights in business class.

Some of the flight segments in this ticket have earlier dates than the `bookings.now()` return value: it means that these flights had already happened. The last flight had not happened yet at the time of the database creation. After the check-in, a boarding pass with the allocated seat number is issued. We can check the exact seats occupied by Antonina (note the outer left join with table `boarding_passes`):

```
SELECT  to_char(f.scheduled_departure, 'DD.MM.YYYY') AS when,
        f.departure_city || ' (' || f.departure_airport || ')' AS departure,
        f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
        f.status,
        bp.seat_no
FROM    ticket_flights tf
        JOIN flights_v f ON tf.flight_id = f.flight_id
        LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
        AND tf.ticket_no = bp.ticket_no
WHERE   tf.ticket_no = '0005432661915'
ORDER BY f.scheduled_departure;
```

when	departure	arrival	status	seat_no

```

29.07.2017 | Moscow (SVO)          | Anadyr (DYR)          | Arrived   | 5C
02.08.2017 | Anadyr (DYR)          | Khabarovsk (KHV)      | Arrived   | 1D

(6 rows)

```

K.5.5. New Booking

Let's try to send Aleksandr Radishchev from Saint Petersburg to Moscow — the route that made him famous. Naturally, he will travel for free and in business class. We have already found a flight for tomorrow, and a return flight a week later.

```
BEGIN;
```

```

INSERT INTO bookings (book_ref, book_date, total_amount)
VALUES      ('_QWE12', bookings.now(), 0);

```

```

INSERT INTO tickets (ticket_no, book_ref, passenger_id, passenger_name)
VALUES      ('_0000000000001', '_QWE12', '1749 051790', 'ALEKSANDR RADISHCHEV');

```

```

INSERT INTO ticket_flights (ticket_no, flight_id, fare_conditions, amount)
VALUES      ('_0000000000001', 8525, 'Business', 0),
            ('_0000000000001', 4967, 'Business', 0);

```

```
COMMIT;
```

To avoid conflicts with the range of values present in the database, identifiers are started with an underscore.

We will check in Aleksandr for tomorrow's flight right away:

```

INSERT INTO boarding_passes (ticket_no, flight_id, boarding_no, seat_no)
VALUES      ('_0000000000001', 8525, 1, '1A');

```

Now let's check the booking information:

```

SELECT      b.book_ref,
            t.ticket_no,
            t.passenger_id,
            t.passenger_name,
            tf.fare_conditions,
            tf.amount,
            f.scheduled_departure_local,
            f.scheduled_arrival_local,
            f.departure_city || ' (' || f.departure_airport || ')' AS departure,
            f.arrival_city || ' (' || f.arrival_airport || ')' AS arrival,
            f.status,
            bp.seat_no
FROM        bookings b
            JOIN tickets t ON b.book_ref = t.book_ref
            JOIN ticket_flights tf ON tf.ticket_no = t.ticket_no
            JOIN flights_v f ON tf.flight_id = f.flight_id
            LEFT JOIN boarding_passes bp ON tf.flight_id = bp.flight_id
                                AND tf.ticket_no = bp.ticket_no
WHERE       b.book_ref = '_QWE12'

```

ORDER BY t.ticket_no, f.scheduled_departure;

```
-[ RECORD 1 ]-----+-----
book_ref      | _QWE12
ticket_no     | _0000000000001
passenger_id  | 1749 051790
passenger_name | ALEKSANDR RADISHCHEV
fare_conditions | Business
amount        | 0.00
scheduled_departure_local | 2017-08-16 09:45:00
scheduled_arrival_local  | 2017-08-16 10:35:00
departure      | St. Petersburg (LED)
arrival        | Moscow (SVO)
status         | On Time
seat_no       | 1A
-[ RECORD 2 ]-----+-----
book_ref      | _QWE12
ticket_no     | _0000000000001
passenger_id  | 1749 051790
passenger_name | ALEKSANDR RADISHCHEV
fare_conditions | Business
amount        | 0.00
scheduled_departure_local | 2017-08-23 10:20:00
scheduled_arrival_local  | 2017-08-23 11:10:00
departure      | Moscow (SVO)
arrival        | St. Petersburg (LED)
status         | Scheduled
seat_no       |
```

We hope that these simple examples helped you get an idea of this demo database.

Appendix L. Acronyms

This is a list of acronyms commonly used in the Postgres Pro documentation and in discussions about Postgres Pro.

Appendix M. Glossary

This is a list of terms and their meaning in the context of PostgreSQL and relational database systems in general.

ACID		Atomicity , Consistency , Isolation , and Durability . This set of properties of database transactions is intended to guarantee validity in concurrent operation and even in event of errors, power failures, etc.
Aggregate function (routine)		A function that combines (<i>aggregates</i>) multiple input values, for example by counting, averaging or adding, yielding a single output value. For more information, see Section 9.21. See Also Window function (routine).
Analytic function		See Window function (routine) .
Analyze (operation)		The process of collecting statistics from data in tables and other relations to help the query planner to make decisions about how to execute queries. (Don't confuse this term with the <code>ANALYZE</code> option to the EXPLAIN command.) For more information, see ANALYZE.
Atomic		In reference to a datum: the fact that its value cannot be broken down into smaller components. In reference to a database transaction: see atomicity.
Atomicity		The property of a transaction that either all its operations complete as a single unit or none do. In addition, if a system failure occurs during the execution of a transaction, no partial results are visible after recovery. This is one of the ACID properties.
Attribute		An element with a certain name and data type found within a tuple .
Autovacuum (process)		A set of background processes that routinely perform vacuum and analyze operations. For more information, see Section 24.1.6.
Backend (process)		Process of an instance which acts on behalf of a client session and handles its requests. (Don't confuse this term with the similar terms Background Worker or Background Writer).
Background (process)	worker	Process within an instance, which runs system- or user-supplied code. Serves as infrastructure for several features in PostgreSQL, such as logical replication and parallel queries. In addition, Extensions can add custom background worker processes. For more information, see Chapter 49.
Background (process)	writer	A process that writes dirty data pages from shared memory to the file system. It wakes up periodically, but works only for a short period in order to distribute its expensive I/O activity over time to avoid generating larger I/O peaks which could block other processes. For more information, see Section 19.4.5.

Bloat	Space in data pages which does not contain current row versions, such as unused (free) space or outdated row versions.
Cast	A conversion of a <i>datum</i> from its current data type to another data type. For more information, see CREATE CAST.
Catalog	The SQL standard uses this term to indicate what is called a <i>database</i> in PostgreSQL's terminology. (Don't confuse this term with <i>system catalog</i>). For more information, see Section 22.1.
Check constraint	A type of <i>constraint</i> defined on a <i>relation</i> which restricts the values allowed in one or more <i>attributes</i>. The check constraint can make reference to any attribute of the same row in the relation, but cannot reference other rows of the same relation or other relations. For more information, see Section 5.4.
Checkpoint	A point in the <i>WAL</i> sequence at which it is guaranteed that the heap and index data files have been updated with all information from <i>shared memory</i> modified before that checkpoint; a <i>checkpoint record</i> is written and flushed to WAL to mark that point. A checkpoint is also the act of carrying out all the actions that are necessary to reach a checkpoint as defined above. This process is initiated when pre-defined conditions are met, such as a specified amount of time has passed, or a certain volume of records has been written; or it can be invoked by the user with the command <code>CHECKPOINT</code>. For more information, see Section 29.4.
Checkpointer (process)	A specialized process responsible for executing checkpoints.
Class (archaic)	See Relation .
Client (process)	Any process, possibly remote, that establishes a <i>session</i> by <i>connecting</i> to an <i>instance</i> to interact with a <i>database</i> .
Column	An <i>attribute</i> found in a <i>table</i> or <i>view</i> .
Commit	The act of finalizing a <i>transaction</i> within the <i>database</i>, which makes it visible to other transactions and assures its <i>durability</i>. For more information, see COMMIT.
Concurrency	The concept that multiple independent operations happen within the <i>database</i> at the same time. In PostgreSQL, concurrency is controlled by the <i>multiversion concurrency control</i> mechanism.
Connection	An established line of communication between a client process and a <i>back-end</i> process, usually over a network, supporting a <i>session</i>. This term is sometimes used as a synonym for session. For more information, see Section 19.3.
Consistency	The property that the data in the <i>database</i> is always in compliance with <i>integrity constraints</i> . Transactions may be allowed to violate some of the constraints transiently before it commits, but if such violations are not resolved

	by the time it commits, such a transaction is automatically <i>rolled back</i> . This is one of the ACID properties.
Constraint	A restriction on the values of data allowed within a <i>table</i>, or in attributes of a <i>domain</i>. For more information, see Section 5.4.
Data area	See Data directory .
Database	A named collection of <i>local SQL objects</i>. For more information, see Section 22.1.
Database cluster	A collection of databases and global SQL objects, and their common static and dynamic metadata. Sometimes referred to as a <i>cluster</i>. In PostgreSQL, the term <i>cluster</i> is also sometimes used to refer to an instance. (Don't confuse this term with the SQL command <code>CLUSTER</code>.)
Database server	See Instance .
Data directory	The base directory on the file system of a <i>server</i> that contains all data files and subdirectories associated with a <i>database cluster</i> (with the exception of <i>tablespaces</i>, and optionally <i>WAL</i>). The environment variable <code>PGDATA</code> is commonly used to refer to the data directory. A <i>cluster</i>'s storage space comprises the data directory plus any additional tablespaces. For more information, see Section 69.1.
Data page	The basic structure used to store relation data. All pages are of the same size. Data pages are typically stored on disk, each in a specific file, and can be read to <i>shared buffers</i> where they can be modified, becoming <i>dirty</i> . They become clean when written to disk. New pages, which initially exist in memory only, are also dirty until written.
Datum	The internal representation of one value of an SQL data type.
Delete	An SQL command which removes <i>rows</i> from a given <i>table</i> or <i>relation</i>. For more information, see DELETE.
Durability	The assurance that once a <i>transaction</i> has been <i>committed</i> , the changes remain even after a system failure or crash. This is one of the ACID properties.
Epoch	See Transaction ID .
Extension	A software add-on package that can be installed on an <i>instance</i> to get extra features. For more information, see Section 39.17.
File segment	A physical file which stores data for a given <i>relation</i>. File segments are limited in size by a configuration value (typically 1 gigabyte), so if a relation exceeds that size, it is split into multiple segments. For more information, see Section 69.1. (Don't confuse this term with the similar term <i>WAL segment</i>).

Foreign data wrapper	A means of representing data that is not contained in the local <i>database</i> so that it appears as if were in local <i>table(s)</i>. With a foreign data wrapper it is possible to define a <i>foreign server</i> and <i>foreign tables</i>. For more information, see CREATE FOREIGN DATA WRAPPER.
Foreign key	A type of <i>constraint</i> defined on one or more <i>columns</i> in a <i>table</i> which requires the value(s) in those <i>columns</i> to identify zero or one <i>row</i> in another (or, infrequently, the same) <i>table</i>.
Foreign server	A named collection of <i>foreign tables</i> which all use the same <i>foreign data wrapper</i> and have other configuration values in common. For more information, see CREATE SERVER.
Foreign table (relation)	A <i>relation</i> which appears to have <i>rows</i> and <i>columns</i> similar to a regular <i>table</i>, but will forward requests for data through its <i>foreign data wrapper</i>, which will return <i>result sets</i> structured according to the definition of the <i>foreign table</i>. For more information, see CREATE FOREIGN TABLE.
Fork	Each of the separate segmented file sets in which a relation is stored. The <i>main fork</i> is where the actual data resides. There also exist two secondary forks for metadata: the <i>free space map</i> and the <i>visibility map</i>. <i>Unlogged relations</i> also have an <i>init fork</i>.
Free space map (fork)	A storage structure that keeps metadata about each data page of a table's main fork. The free space map entry for each page stores the amount of free space that's available for future tuples, and is structured to be efficiently searched for available space for a new tuple of a given size. For more information, see Section 69.3.
Function (routine)	A type of routine that receives zero or more arguments, returns zero or more output values, and is constrained to run within one transaction. Functions are invoked as part of a query, for example via <code>SELECT</code>. Certain functions can return <i>sets</i>; those are called <i>set-returning functions</i>. Functions can also be used for <i>triggers</i> to invoke. For more information, see CREATE FUNCTION.
Grant	An SQL command that is used to allow a <i>user</i> or <i>role</i> to access specific objects within the <i>database</i>. For more information, see GRANT.
Heap	Contains the values of <i>row</i> attributes (i.e., the data) for a <i>relation</i>. The heap is realized within one or more <i>file segments</i> in the relation's <i>main fork</i>.
Host	A computer that communicates with other computers over a network. This is sometimes used as a synonym for <i>server</i>. It is also used to refer to a computer where <i>client processes</i> run.
Index (relation)	A <i>relation</i> that contains data derived from a <i>table</i> or <i>materialized view</i>. Its internal structure supports fast retrieval of and access to the original data. For more information, see CREATE INDEX.
Insert	An SQL command used to add new data into a <i>table</i>.

For more information, see [INSERT](#).

Instance	A group of backend and auxiliary processes that communicate using a common shared memory area. One postmaster process manages the instance; one instance manages exactly one database cluster with all its databases. Many instances can run on the same server as long as their TCP ports do not conflict. The instance handles all key features of a DBMS: read and write access to files and shared memory, assurance of the ACID properties, connections to client processes, privilege verification, crash recovery, replication, etc.
Isolation	The property that the effects of a transaction are not visible to concurrent transactions before it commits. This is one of the ACID properties. For more information, see Section 13.2.
Join	An operation and SQL keyword used in queries for combining data from multiple relations.
Key	A means of identifying a row within a table or other relation by values contained within one or more attributes in that relation.
Lock	A mechanism that allows a process to limit or prevent simultaneous access to a resource.
Log file	Log files contain human-readable text lines about events. Examples include login failures, long-running queries, etc. For more information, see Section 24.3.
Logged	A table is considered logged if changes to it are sent to the WAL. By default, all regular tables are logged. A table can be specified as unlogged either at creation time or via the <code>ALTER TABLE</code> command.
Logger (process)	If activated, the process writes information about database events into the current log file. When reaching certain time- or volume-dependent criteria, a new log file is created. Also called syslogger. For more information, see Section 19.8.
Log record	Archaic term for a WAL record.
Master (server)	See Primary (server).
Materialized	The property that some information has been pre-computed and stored for later use, rather than computing it on-the-fly. This term is used in materialized view, to mean that the data derived from the view's query is stored on disk separately from the sources of that data. This term is also used to refer to some multi-step queries to mean that the data resulting from executing a given step is stored in memory (with the possibility of spilling to disk), so that it can be read multiple times by another step.
Materialized view (relation)	A relation that is defined by a <code>SELECT</code> statement (just like a view), but stores data in the same way that a table does. It cannot be modified via <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> operations.

	For more information, see CREATE MATERIALIZED VIEW .
Multi-version concurrency control (MVCC)	A mechanism designed to allow several transactions to be reading and writing the same rows without one process causing other processes to stall. In PostgreSQL, MVCC is implemented by creating copies (<i>versions</i>) of tuples as they are modified; after transactions that can see the old versions terminate, those old versions need to be removed.
Null	A concept of non-existence that is a central tenet of relational database theory. It represents the absence of a definite value.
Optimizer	See Query planner .
Parallel query	The ability to handle parts of executing a query to take advantage of parallel processes on servers with multiple CPUs.
Partition	One of several disjoint (not overlapping) subsets of a larger set. In reference to a partitioned table : One of the tables that each contain part of the data of the partitioned table, which is said to be the <i>parent</i> . The partition is itself a table, so it can also be queried directly; at the same time, a partition can sometimes be a partitioned table, allowing hierarchies to be created. In reference to a window function in a query , a partition is a user-defined criterion that identifies which neighboring rows of the query's result set can be considered by the function.
Partitioned table (relation)	A relation that is in semantic terms the same as a table , but whose storage is distributed across several partitions .
Postmaster (process)	The very first process of an instance . It starts and manages the other auxiliary processes and creates backend processes on demand. For more information, see Section 18.3 .
Primary key	A special case of a unique constraint defined on a table or other relation that also guarantees that all of the attributes within the primary key do not have null values. As the name implies, there can be only one primary key per table, though it is possible to have multiple unique constraints that also have no null-capable attributes.
Primary (server)	When two or more databases are linked via replication , the server that is considered the authoritative source of information is called the <i>primary</i> , also known as a <i>master</i> .
Procedure (routine)	A type of routine. Their distinctive qualities are that they do not return values, and that they are allowed to make transactional statements such as COMMIT and ROLLBACK. They are invoked via the CALL command. For more information, see CREATE PROCEDURE .
Query	A request sent by a client to a backend , usually to return results or to modify data on the database.
Query planner	The part of PostgreSQL that is devoted to determining (<i>planning</i>) the most efficient way to execute queries . Also known as <i>query optimizer</i> , <i>optimizer</i> , or simply <i>planner</i> .
Record	See Tuple .

Recycling	See WAL file .
Referential integrity	A means of restricting data in one relation by a foreign key so that it must have matching data in another relation .
Relation	The generic term for all objects in a database that have a name and a list of attributes defined in a specific order. Tables, sequences, views, foreign tables, materialized views, composite types, and indexes are all relations. More generically, a relation is a set of tuples; for example, the result of a query is also a relation. In PostgreSQL, <i>Class</i> is an archaic synonym for <i>relation</i>.
Replica (server)	A database that is paired with a primary database and is maintaining a copy of some or all of the primary database's data. The foremost reasons for doing this are to allow for greater access to that data, and to maintain availability of the data in the event that the primary becomes unavailable.
Replication	The act of reproducing data on one server onto another server called a replica . This can take the form of <i>physical replication</i> , where all file changes from one server are copied verbatim, or <i>logical replication</i> where a defined subset of data changes are conveyed using a higher-level representation.
Result set	A relation transmitted from a backend process to a client upon the completion of an SQL command, usually a <code>SELECT</code> but it can be an <code>INSERT</code>, <code>UPDATE</code>, or <code>DELETE</code> command if the <code>RETURNING</code> clause is specified. The fact that a result set is a relation means that a query can be used in the definition of another query, becoming a <i>subquery</i>.
Revoke	A command to prevent access to a named set of database objects for a named list of roles. For more information, see REVOKE.
Role	A collection of access privileges to the instance. Roles are themselves a privilege that can be granted to other roles. This is often done for convenience or to ensure completeness when multiple users need the same privileges. For more information, see CREATE ROLE.
Rollback	A command to undo all of the operations performed since the beginning of a transaction. For more information, see ROLLBACK.
Routine	A defined set of instructions stored in the database system that can be invoked for execution. A routine can be written in a variety of programming languages. Routines can be functions (including set-returning functions and trigger functions), aggregate functions, and procedures. Many routines are already defined within PostgreSQL itself, but user-defined ones can also be added.
Row	See Tuple .
Savepoint	A special mark in the sequence of steps in a transaction . Data modifications after this point in time may be reverted to the time of the savepoint.

For more information, see [SAVEPOINT](#).

Schema

A schema is a namespace for [SQL objects](#), which all reside in the same [database](#). Each SQL object must reside in exactly one schema.

All system-defined SQL objects reside in schema `pg_catalog`.

More generically, the term *schema* is used to mean all data descriptions ([table](#) definitions, [constraints](#), comments, etc) for a given [database](#) or subset thereof.

For more information, see [Section 5.9](#).

Segment

See [File segment](#).

Select

The SQL command used to request data from a [database](#). Normally, `SELECT` commands are not expected to modify the [database](#) in any way, but it is possible that [functions](#) invoked within the query could have side effects that do modify data.

For more information, see [SELECT](#).

Sequence (relation)

A type of relation that is used to generate values. Typically the generated values are sequential non-repeating numbers. They are commonly used to generate surrogate [primary key](#) values.

Server

A computer on which PostgreSQL [instances](#) run. The term *server* denotes real hardware, a container, or a *virtual machine*.

This term is sometimes used to refer to an instance or to a host.

Session

A state that allows a client and a backend to interact, communicating over a [connection](#).

Shared memory

RAM which is used by the processes common to an [instance](#). It mirrors parts of [database](#) files, provides a transient area for [WAL records](#), and stores additional common information. Note that shared memory belongs to the complete instance, not to a single database.

The largest part of shared memory is known as *shared buffers* and is used to mirror part of data files, organized into pages. When a page is modified, it is called a dirty page until it is written back to the file system.

For more information, see [Section 19.4.1](#).

SQL object

Any object that can be created with a `CREATE` command. Most objects are specific to one database, and are commonly known as *local objects*.

Most local objects belong to a specific [schema](#) in their containing database, such as [relations](#) (all types), [routines](#) (all types), data types, etc. The names of such objects of the same type in the same schema are enforced to be unique.

There also exist local objects that do not belong to schemas; some examples are [extensions](#), [data type casts](#), and [foreign data wrappers](#). The names of such objects of the same type are enforced to be unique within the database.

Other object types, such as [roles](#), [tablespaces](#), replication origins, subscriptions for logical replication, and databases themselves are not local SQL objects since they exist entirely outside of any specific database; they are

	called <i>global objects</i>. The names of such objects are enforced to be unique within the whole database cluster. For more information, see Section 22.1.
SQL standard	A series of documents that define the SQL language.
Standby (server)	See Replica (server) .
Stats collector (process)	This process collects statistical information about the <i>instance</i>'s activities. For more information, see Section 27.2.
System catalog	A collection of <i>tables</i> which describe the structure of all <i>SQL objects</i> of the instance. The system catalog resides in the schema <code>pg_catalog</code>. These tables contain data in internal representation and are not typically considered useful for user examination; a number of user-friendlier <i>views</i>, also in schema <code>pg_catalog</code>, offer more convenient access to some of that information, while additional tables and views exist in schema <code>information_schema</code> (see Chapter 38) that expose some of the same and additional information as mandated by the <i>SQL standard</i>. For more information, see Section 5.9.
Table	A collection of <i>tuples</i> having a common data structure (the same number of <i>attributes</i>, in the same order, having the same name and type per position). A table is the most common form of <i>relation</i> in PostgreSQL. For more information, see CREATE TABLE.
Tablespace	A named location on the server file system. All <i>SQL objects</i> which require storage beyond their definition in the <i>system catalog</i> must belong to a single tablespace. Initially, a database cluster contains a single usable tablespace which is used as the default for all SQL objects, called <code>pg_default</code>. For more information, see Section 22.6.
Temporary table	<i>Tables</i> that exist either for the lifetime of a <i>session</i> or a <i>transaction</i>, as specified at the time of creation. The data in them is not visible to other sessions, and is not <i>logged</i>. Temporary tables are often used to store intermediate data for a multi-step operation. For more information, see CREATE TABLE.
TOAST	A mechanism by which large attributes of table rows are split and stored in a secondary table, called the <i>TOAST table</i>. Each relation with large attributes has its own TOAST table. For more information, see Section 69.2.
Transaction	A combination of commands that must act as a single <i>atomic</i> command: they all succeed or all fail as a single unit, and their effects are not visible to other <i>sessions</i> until the transaction is complete, and possibly even later, depending on the isolation level. For more information, see Section 13.2.
Transaction ID	The numerical, unique, sequentially-assigned identifier that each transaction receives when it first causes a database modification. Frequently abbreviated as <i>xid</i> . When stored on disk, xids are only 32-bits wide, so only approximately four billion write transaction IDs can be generated; to per-

mit the system to run for longer than that, *epochs* are used, also 32 bits wide. When the counter reaches the maximum xid value, it starts over at 3 (values under that are reserved) and the epoch value is incremented by one. In some contexts, the epoch and xid values are considered together as a single 64-bit value.

For more information, see [Section 8.19](#).

Transactions per second (TPS) Average number of transactions that are executed per second, totaled across all sessions active for a measured run. This is used as a measure of the performance characteristics of an instance.

Trigger A [function](#) which can be defined to execute whenever a certain operation (INSERT, UPDATE, DELETE, TRUNCATE) is applied to a [relation](#). A trigger executes within the same [transaction](#) as the statement which invoked it, and if the function fails, then the invoking statement also fails.

For more information, see [CREATE TRIGGER](#).

Tuple A collection of [attributes](#) in a fixed order. That order may be defined by the [table](#) (or other [relation](#)) where the tuple is contained, in which case the tuple is often called a *row*. It may also be defined by the structure of a result set, in which case it is sometimes called a *record*.

Unique constraint A type of [constraint](#) defined on a [relation](#) which restricts the values allowed in one or a combination of columns so that each value or combination of values can only appear once in the relation — that is, no other row in the relation contains values that are equal to those.

Because [null values](#) are not considered equal to each other, multiple rows with null values are allowed to exist without violating the unique constraint.

Unlogged The property of certain [relations](#) that the changes to them are not reflected in the [WAL](#). This disables replication and crash recovery for these relations.

The primary use of unlogged tables is for storing transient work data that must be shared across processes.

[Temporary tables](#) are always unlogged.

Update An SQL command used to modify [rows](#) that may already exist in a specified [table](#). It cannot create or remove rows.

For more information, see [UPDATE](#).

User A [role](#) that has the `LOGIN` privilege.

User mapping The translation of login credentials in the local [database](#) to credentials in a remote data system defined by a [foreign data wrapper](#).

For more information, see [CREATE USER MAPPING](#).

Vacuum The process of removing outdated [tuple versions](#) from tables or materialized views, and other closely related processing required by PostgreSQL's implementation of [MVCC](#). This can be initiated through the use of the `VACUUM` command, but can also be handled automatically via [autovacuum](#) processes.

For more information, see [Section 24.1](#) .

View A [relation](#) that is defined by a `SELECT` statement, but has no storage of its own. Any time a query references a view, the definition of the view is sub-

stituted into the query as if the user had typed it as a subquery instead of the name of the view.

For more information, see [CREATE VIEW](#).

Visibility map (fork)	A storage structure that keeps metadata about each data page of a table's main fork. The visibility map entry for each page stores two bits: the first one (<code>all-visible</code>) indicates that all tuples in the page are visible to all transactions. The second one (<code>all-frozen</code>) indicates that all tuples in the page are marked frozen.
WAL	See Write-ahead log .
WAL archiver (process)	A process that saves copies of WAL files for the purpose of creating backups or keeping replicas current. For more information, see Section 25.3 .
WAL file	Also known as <i>WAL segment</i> or <i>WAL segment file</i> . Each of the sequentially-numbered files that provide storage space for WAL . The files are all of the same predefined size and are written in sequential order, interspersing changes as they occur in multiple simultaneous sessions. If the system crashes, the files are read in order, and each of the changes is replayed to restore the system to the state it was in before the crash. Each WAL file can be released after a checkpoint writes all the changes in it to the corresponding data files. Releasing the file can be done either by deleting it, or by changing its name so that it will be used in the future, which is called <i>recycling</i> . For more information, see Section 29.6 .
WAL record	A low-level description of an individual data change. It contains sufficient information for the data change to be re-executed (<i>replayed</i>) in case a system failure causes the change to be lost. WAL records use a non-printable binary format. For more information, see Section 29.6 .
WAL segment	See WAL file .
WAL writer (process)	A process that writes WAL records from shared memory to WAL files . For more information, see Section 19.5 .
Window function (routine)	A type of function used in a query that applies to a partition of the query's result set ; the function's result is based on values found in rows of the same partition or frame. All aggregate functions can be used as window functions, but window functions can also be used to, for example, give ranks to each of the rows in the partition. Also known as <i>analytic functions</i> . For more information, see Section 3.5 .
Write-ahead log	The journal that keeps track of the changes in the database cluster as user- and system-invoked operations take place. It comprises many individual WAL records written sequentially to WAL files .

Appendix N. Color Support

Most programs in the PostgreSQL package can produce colorized console output. This appendix describes how that is configured.

N.1. When Color is Used

To use colorized output, set the environment variable `PG_COLORS` as follows:

1. If the value is `always`, then color is used.
2. If the value is `auto` and the standard error stream is associated with a terminal device, then color is used.
3. Otherwise, color is not used.

N.2. Configuring the Colors

The actual colors to be used are configured using the environment variable `PG_COLORS` (note plural). The value is a colon-separated list of *key=value* pairs. The keys specify what the color is to be used for. The values are SGR (Select Graphic Rendition) specifications, which are interpreted by the terminal.

The following keys are currently in use:

`error`

used to highlight the text “error” in error messages

`warning`

used to highlight the text “warning” in warning messages

`locus`

used to highlight location information (e.g., program name and file name) in messages

The default value is `error=01;31:warning=01;35:locus=01` (01;31 = bold red, 01;35 = bold magenta, 01 = bold default color).

Tip

This color specification format is also used by other software packages such as GCC, GNU coreutils, and GNU grep.

Appendix O. Obsolete or Renamed Features

Functionality is sometimes removed from PostgreSQL, feature, setting and file names sometimes change, or documentation moves to different places. This section directs users coming from old versions of the documentation or from external links to the appropriate new location for the information they need.

O.1. `recovery.conf` file merged into `postgresql.conf`

Postgres Pro 11 and below used a configuration file named `recovery.conf` to manage replicas and standbys. Support for this file was removed in Postgres Pro 12. See [the release notes for PostgreSQL 12](#) for details on this change.

On Postgres Pro 12 and above, [archive recovery](#), [streaming replication](#), and [PITR](#) are configured using [normal server configuration parameters](#). These are set in `postgresql.conf` or via `ALTER SYSTEM` like any other parameter.

The server will not start if a `recovery.conf` exists.

The `trigger_file` setting has been renamed to [promote_trigger_file](#).

The `standby_mode` setting has been removed. A `standby.signal` file in the data directory is used instead. See [Standby Server Operation](#) for details.

O.2. `pg_xlogdump` renamed to `pg_waldump`

Postgres Pro 9.6 and below provided a command named `pg_xlogdump` to read write-ahead-log (WAL) files. This command was renamed to `pg_waldump`, see [pg_waldump](#) for documentation of `pg_waldump` and see [the release notes for PostgreSQL 10](#) for details on this change.

O.3. `pg_resetxlog` renamed to `pg_resetwal`

Postgres Pro 9.6 and below provided a command named `pg_resetxlog` to reset the write-ahead-log (WAL) files. This command was renamed to `pg_resetwal`, see [pg_resetwal](#) for documentation of `pg_resetwal` and see [the release notes for PostgreSQL 10](#) for details on this change.

O.4. `pg_receivexlog` renamed to `pg_receivewal`

Postgres Pro 9.6 and below provided a command named `pg_receivexlog` to fetch write-ahead-log (WAL) files. This command was renamed to `pg_receivewal`, see [pg_receivewal](#) for documentation of `pg_receivewal` and see [the release notes for PostgreSQL 10](#) for details on this change.

Bibliography

Selected references and readings for SQL and PostgreSQL.

Some white papers and technical reports from the original POSTGRES development team are available at the University of California, Berkeley, Computer Science Department [web site](#).
